vmware by Broadcom

VMware vSphere 9.1

Contents

Release Notes 67
vSphere Express 68
ESX Installation and Setup 70
Installing and Setting Up ESX 70
How to Install ESX 70
Preparing for Installing ESX 71
Download the ESX Installer 71
Required Information for ESX Installation 71
Media Options for Booting the ESX Installer 72
ESX Requirements 75
ESX System Storage Overview 75
ESX Hardware Requirements 79
Using Remote Management Applications 80
Recommendations for Enhanced ESX Performance 81
Required Free Space for System Logging 82
VMware Host Client System Requirements 83
What is VMware vSphere Distributed Services Engine® 83
High Availability with VMware vSphere Distributed Services Engine 85
Error Handling, Failover, and Rollback for VMware vSphere Distributed Services Engine 85
Customizing Installations with vSphere ESX Image Builder 86
How the vSphere ESX Image Builder Works 86
Image Profiles 88
Working with Acceptance Levels 88
Change the Host Acceptance Level 89
Set the Image Profile Acceptance Level 90
Structure of ImageProfile, SoftwarePackage, and ImageProfileDiff Objects 90
Configure vSphere ESX Image Builder 93
Configure the vSphere ESX Image Builder 94
Using VMware.ImageBuilder Cmdlets 94
VMware.ImageBuilder Cmdlets Overview 95
ESX Image Profile Tasks 96
Add a Software Depot 96
Import a Software Depot 97
Clone an Image Profile 98
Create an Image Profile 99
Edit an Image Profile 102
Compare Image Profiles 103
Move an Image Profile to a Different Software Depot 105
Export an Image Profile to ISO or Offline Bundle ZIP 105

Regenerate an Image Profile ... 107
Preserve Image Profiles Across Sessions with VCF PowerCLI ... 107
Compare VIBs with VCF PowerCLI Cmdlets ... 107
vSphere ESX Image Builder Workflows with VCF PowerCLI Cmdlets ... 108
Examine Depot Contents ... 108
Create Image Profiles by Cloning Workflow ... 109
Create New Image Profiles Workflow ... 110
Edit Image Profiles Workflow ... 111
Installing ESX ... 113
Installing ESX Interactively ... 113
Install ESX Interactively ... 113
Install ESX on a Software iSCSI Disk ... 115
Installing ESX by Using a Script ... 115
Scripted ESX Installation ... 116
Installation and Upgrade Scripts Used for ESX Installation ... 118
Configuring External Entropy Sources During Scripted Installation ... 128
Network Booting the ESX Installer ... 132
Overview of the Network Boot Installation Process ... 132
Network Boot Background Information ... 133
PXELINUX Configuration Files ... 134
Boot the ESX Installer by Using PXE and TFTP ... 135
Boot the ESX Installer by Using iPXE and HTTP ... 137
Boot the ESX Installer by Using Native UEFI HTTP ... 138
Sample DHCP Configurations ... 140
Installing ESX Using vSphere Auto Deploy ... 143
Understanding vSphere Auto Deploy ... 143
Install and Configure vSphere Auto Deploy ... 148
How vSphere Auto Deploy Works with VCF PowerCLI ... 151
vSphere Auto Deploy Tasks by Using the vSphere Client ... 159
Provision ESX Hosts with vSphere Auto Deploy ... 171
Use vSphere Auto Deploy for Stateless Caching and Stateful Installs ... 179
Configure a Host Profile to Use Stateless Caching ... 181
Configure a Host Profile to Enable Stateful Installs ... 184
Setting Up a vSphere Auto Deploy Reference Host ... 186
Configure an ESX Dump Collector ... 186
Configure Syslog from Host Profiles in the vSphere Client ... 187
Enable NTP Client on a Reference Host in the vSphere Client ... 188
Configure Networking for Your vSphere Auto Deploy Host in the vSphere Client ... 188
Configure a Reference Host for Auto-Partitioning ... 189
Converting Stateless Hosts to Stateful Hosts ... 189
Using Zero Touch Provisioning ... 193
vSphere Auto Deploy Best Practices ... 200
vSphere PowerCLI Scenario for vSphere Auto Deploy ... 206

Troubleshooting vSphere Auto Deploy....212
vSphere Auto Deploy Rule Takes Long to Complete....213
vSphere Auto Deploy TFTP Timeout Error at Boot Time....213
vSphere Auto Deploy Host Boots with Wrong Configuration....213
Host Is Not Redirected to vSphere Auto Deploy Server....213
Package Warning Message When You Assign an Image Profile to a vSphere Auto Deploy Host....214
vSphere Auto Deploy Host with a Built-In USB Flash Drive Does Not Send Coredumps to Local Disk....214
vSphere Auto Deploy Host Reboots After Five Minutes....214
vSphere Auto Deploy Host Cannot Contact TFTP Server....215
vSphere Auto Deploy Host Cannot Retrieve ESX Image from vSphere Auto Deploy Server....215
vSphere Auto Deploy Host Does Not Get a DHCP Assigned Address....216
vSphere Auto Deploy Host Does Not Network Boot....216
Recovering from Database Corruption on the vSphere Auto Deploy Server....216
Setting Up ESX....217
Initial ESX Configuration....217
ESX Autoconfiguration....217
Managing ESX Remotely....218
About the Direct Console ESX Interface....218
Configure the Keyboard Layout for the Direct Console....218
Create a Security Banner for the Direct Console....218
Redirecting the Direct Console to a Serial Port....219
Redirect the Direct Console to a Serial Port by Setting the Boot Options Manually....219
Redirect the Direct Console to a Serial Port from the vSphere Client....219
Redirect the Direct Console to a Serial Port in a Host Deployed with Auto Deploy....220
Enable ESX Shell and SSH Access with the Direct Console User Interface....220
Set the Password for the Administrator Account....221
Configuring the BIOS Boot Settings....221
Change the BIOS Boot Setting for ESX....221
Configure the Boot Setting for Virtual Media....222
Configuring Network Settings....222
Network Access to Your ESX Host....222
Choose Network Adapters for the Management Network....223
Set the VLAN ID....223
Configuring IP Settings for ESX....223
Configure IP Settings from the Direct Console....224
Configure IP Settings from the vSphere Client....224
Configuring DNS for ESX....224
Configure DNS Settings from the Direct Console....224
Configure DNS Suffixes....225
Configure the Network Settings on a Host That Is Not Attached to the Network....225
Test the Management Network....225
Restart the Management Agents....225
Restart the Management Network....226

Test Connectivity to Devices and Networks ... 226
Restoring the Standard Switch ... 226
Configuring System Logging ... 226
Configure Syslog on ESX Hosts ... 227
Fine-tune Syslog on ESX Hosts ... 228
ESX Syslog Options ... 233
Protocols, Formats, and Framing of ESX Syslog Messages ... 237
Log File Formats ... 238
ESX Syslog Message Transmission Formats ... 240
Configure Log Filtering on ESX Hosts ... 242
Set the Host Image Profile Acceptance Level ... 243
Remove All Custom Packages on ESX ... 243
Modify ESX Configuration Files ... 244
Deactivate Support for Non-ASCII Characters on ESX ... 244
Reset the System Configuration ... 244
After You Install and Set Up ESX ... 245
View System Logs ... 245
Troubleshooting ESX Booting ... 245
Host Stops Unexpectedly at Bootup When Sharing a Boot Disk with Another Host ... 245
Host Fails to Boot After You Install ESX in UEFI Mode ... 246
Decommission an ESX Host ... 246
ESX Upgrade ... 248
Overview of the ESX Host Upgrade Process ... 248
Upgrading Virtual Machines and VMware Tools ... 250
Before Upgrading ESX Hosts ... 251
Upgrading Hosts That Have Third-Party Custom VIBs ... 251
Upgrading ESX Hosts in an Environment With VMware NSX ... 252
Upgrade Hosts Interactively ... 252
Installing or Upgrading Hosts by Using a Script ... 253
How to Upgrade Hosts by Using ESXCLI Commands ... 253
Upgrading Hosts by Using ESXCLI Commands ... 254
VIBs, Image Profiles, and Software Depots ... 254
Understanding Acceptance Levels for VIBs and Hosts ... 254
Match a Host Acceptance Level with an Update Acceptance Level ... 255
See if ESX Host Update Requires Maintenance Mode or Reboot ... 256
Place a Host in Maintenance Mode ... 256
Update a Host with Individual VIBs ... 257
Upgrade or Update a Host with Image Profiles ... 258
Update ESX Hosts by Using Zip Files ... 260
Remove VIBs from a Host ... 261
Add Third-Party Extensions to Hosts with an ESXCLI Command ... 264
Perform a Dry Run of an ESXCLI Installation or Upgrade ... 264
List the Available VIBs and Profiles After Host Reboot ... 264

Display the Image Profile and Acceptance Level of the Host....265
Using vSphere Auto Deploy to Reprovision Hosts....265
After You Upgrade ESX Hosts....265
Run the Secure Boot Validation Script After ESX Upgrade....266
Configure System Logging....267
Collect Logs for Troubleshooting Failed ESX Upgrades....267
vCenter Deployment and Setup....268
Introduction to vSphere Deployment and Setup....268
How to Deploy and Set Up vSphere....268
vCenter Components and Services....270
What is the vCenter Appliance....271
Understanding vSphere Domains and Domain Names....271
vCenter Enhanced Linked Mode....271
vCenter Enhanced Linked Mode for vCenter Appliance....272
Deploying the vCenter Appliance....273
System Requirements for the vCenter Appliance....274
Hardware Requirements for the vCenter Appliance....274
Storage Requirements for the vCenter Appliance....274
Software Requirements for the vCenter Appliance....275
DNS Requirements for the vCenter Appliance....275
vSphere Client Software Requirements....276
Preparing for Deployment of the vCenter Appliance....276
System Requirements for the vCenter Installer....276
Download and Mount the vCenter Installer....277
Synchronizing the Client and Server System Clock....278
Prerequisites for Deploying the vCenter Appliance....278
GUI Deployment of the vCenter Appliance....279
Required Information for Deploying a vCenter Appliance....279
Deploy the vCenter Appliance by Using the GUI....282
CLI Deployment of the vCenter Appliance....286
Prepare Your JSON Configuration File for CLI Deployment....286
Syntax of the CLI Deployment Command....297
Deploy a vCenter Appliance by Using the CLI....298
Deploy Multiple vCenter Appliances Using the CLI....299
File-Based Backup and Restore of vCenter....299
Considerations and Limitations for File-Based Backup and Restore....300
Schedule a File-Based Backup....302
Manually Back Up vCenter by Using the vCenter Management Interface....303
Restore vCenter from a File-Based Backup....304
Stage 1 - Deploy a New Appliance....306
Stage 2 - Transfer Data to the Newly Deployed Appliance....308
Image-Based Backup and Restore of a vCenter Environment....309
Considerations and Limitations for Image-Based Backup and Restore....309

Restore a vCenter Image-based Environment..... 311
Restore a vCenter Instance.....313
Restore a vCenter Enhanced Linked Mode Environment.....313
After You Deploy the vCenter Appliance.....313
Log in to Your vCenter.....314
Repoint vCenter to Another vCenter in a Different Domain.....314
Repoint a Single vCenter Node to an Existing vCenter Single Sign-On Domain without a Replication Partner.....314
Repoint a vCenter Node to an Existing vCenter Single Sign-On Domain with a Replication Partner..... 316
Repoint a vCenter Node to a New vCenter Single Sign-On Domain.....318
Syntax of the Domain Repoint Command.....320
Understanding Tagging and Authorization Conflicts.....321
vCenter Domain Repoint License Considerations..... 324
Troubleshooting vCenter Deployment..... 324
Collecting Logs for Troubleshooting a vCenter Deployment or Upgrade.....324
Retrieve Installation Logs Manually.....325
Collect Deployment Log Files for the vCenter Appliance..... 325
Export a vCenter Support Bundle for Troubleshooting..... 325
vCenter Upgrade..... 326
vSphere Upgrade Options.....326
How to Upgrade vSphere..... 326
Overview of the vCenter Upgrade Process.....328
vCenter Upgrade Compatibility.....329
Differences Between vSphere Upgrades, Patches, and Updates.....330
Component Behavior Changes That Affect vCenter Upgrade..... 330
Support for Upgrading a vCenter with Multi-Homing..... 331
Support for Federal Information Processing Standard 140-2.....331
Support for Transport Security Layer 1.3.....331
Upgrading the vCenter Appliance.....331
About the Upgrade Process of the vCenter appliance.....333
Preparing to Upgrade the vCenter appliance.....333
Transferring Data from an Existing vCenter Appliance.....334
Prepare ESX Hosts for vCenter Appliance Upgrade..... 334
Prerequisites for Upgrading the vCenter Appliance..... 335
GUI Upgrade of the vCenter Appliance.....336
Required Information for Upgrading a vCenter Appliance 8.0 and Later to Version 9.1..... 337
Upgrade a vCenter Appliance 8.0 or later to Version 9.1 by Using the GUI.....340
Upgrading vCenter in High Availability Environments..... 346
Prerequisites for Upgrading vCenter High Availability Environments.....346
Upgrade a vCenter Appliance HA Cluster by Using the GUI.....346
CLI Upgrade of the vCenter Appliance..... 352
Prepare Your JSON Configuration File for CLI Upgrade..... 352
Upgrade a vCenter Appliance by Using the CLI.....361

Syntax of the CLI Upgrade Command....362
Reduced Downtime Upgrade....363
About the Reduced Downtime Upgrade Process....364
Reduced Downtime Upgrade in High Availability Environments....364
Reduced Downtime GUI Upgrade....364
Configure a Custom Repository URL....365
Download and Mount the ISO Image....366
Download Updates from the Broadcom Online Repository....366
Upgrade the vCenter Lifecycle Plug-in....367
Configure the Target vCenter appliance....369
Prepare Upgrade and Switch Over to the Target vCenter appliance....370
Reduced Downtime CLI Upgrade....371
Prepare Your JSON Configuration File for the Reduced Downtime CLI Upgrade....371
JSON Templates for the Reduced Downtime CLI Upgrade....371
Perform a Reduced Downtime Upgrade by Using the CLI....372
After Upgrading vCenter....372
Verify Your vCenter Upgrade Is Successful....373
Reregister Plug-In Solution in vCenter After Upgrade or Migration....373
Monitor and Manage Historical Data Migration....374
Managing Software Updates, Upgrades, and Product Compatibility....374
Monitor Interoperability for the Current vCenter Version....375
Generate an Interoperability Report for Target vCenter Versions....376
Generate Pre-Update Reports....377
Use the Latest Interoperability Data in an Air-Gapped Environment....377
Patching and Updating vCenter 9.1 Deployments....378
vCenter Quick Patches....379
Patching vCenter Using the vCenter Management Interface....379
Automatic Creation of LVM Snapshot....379
Check for and Stage Patches to the vCenter Appliance....382
Configure the Repository for URL-Based Patching....383
Install vCenter Patches....384
Enable Automatic Checks for vCenter Patches....385
Patching the vCenter Appliance by Using the Appliance Shell....385
View a List of All Installed Patches in the vCenter Appliance....385
Configure URL-Based Patching....386
Stage Patches to the vCenter Appliance....387
Install vCenter Patches....388
Patching a vCenter High Availability Environment....389
Troubleshooting vCenter Upgrade....389
Errors and Warnings Returned by the Installation and Upgrade Precheck Script....389
Upgrade Issues with vCenter Containing Host Profiles....391
vCenter Configuration....392
How to Configure vCenter....392

Using the vCenter Management Interface to Configure vCenter....393
Log In to the vCenter Appliance Management Interface....393
View vCenter Health Status....393
Reboot or Shut Down vCenter....394
Create a Support Bundle....394
Monitor CPU and Memory Use....394
Monitor Disk Use....395
Monitor Network Use....395
Monitor Database Use....395
Enable or Disable SSH and Bash Shell Access....396
Configure the DNS, IP Address, and Proxy Settings....396
Reconfigure the Primary Network Identifier....398
Edit the Firewall Settings....399
Configure the System Time Zone and Time Synchronization Settings....399
Start, Stop, and Restart Services....400
Configure Update Settings....400
Change the Password and Password Expiration Settings of the Root User....401
Forward vCenter Log Files to Remote Syslog Server....401
Configure Log Insight Agent to Send Custom vCenter Logs to Log Management....402
Configure and Schedule Backups....403
Using the vSphere Client to Configure vCenter....404
Configuring vCenter....404
Configuring Statistics Settings....404
Configure Runtime Settings for vCenter....405
Configure User Directory Settings....405
Configure Mail Sender Settings....406
Configure SNMP Settings....407
View Port Settings....408
Configure the Timeout Settings for the vSphere Client....408
Configure Logging Options....408
Configure Advanced Settings....409
Send a Message to Other Logged In Users....409
Add a User to the SystemConfiguration.BashShellAdministrators Group....409
Reboot a Node....410
Export a Support Bundle....410
Using the Appliance Shell to Configure vCenter....410
Access the Appliance Shell....411
Enable and Access the Bash Shell from the Appliance Shell....411
Keyboard Shortcuts for Editing Commands....411
Get Help on APIs and Utilities....412
Plug-Ins in vCenter Shell....412
Browse Log Files Using showlog Plug-In....413
API Commands in Appliance Shell....413

Configuring SNMP for vCenter....418
Configure the SNMP Agent for Polling....418
Configure vCenter for SNMP v1 and v2c....418
Configure vCenter for SNMP v3....419
Configure SNMP Agent to Filter Notifications....421
Configure SNMP Management Client Software....422
Reset SNMP Settings to Factory Defaults....422
Configuring Time Synchronization Settings in vCenter....422
Use VMware Tools Time Synchronization....423
Add or Replace NTP Servers in the vCenter Configuration....423
Synchronize the Time in vCenter with an NTP Server....423
Managing Appliance Local User Accounts in vCenter....424
User Roles in vCenter....424
Get a List of the Appliance Local User Accounts in vCenter....424
Create an Appliance Local User Account in vCenter....424
Update Password of an Appliance Local User in vCenter....425
Update an Appliance Local User Account in vCenter....425
Delete an Appliance Local User Account in vCenter....426
Monitor Health Status and Statistics in vCenter....426
Using the Direct Console User Interface to Configure vCenter....426
Log In to the Direct Console User Interface....426
Change the Password of the Root User....427
Configure the Management Network of vCenter....427
Restart the Management Network of vCenter....428
Enable Access to the Bash Shell....428
Access the Bash Shell for Troubleshooting....428
vSphere Authentication....429
Getting Started with vSphere Certificate Management and Authentication....429
vSphere Authentication Options....431
Managing vCenter Certificates....432
Manage vCenter Certificates Using the vSphere Client....432
Manage vCenter Certificates Using CLIs....432
Managing vCenter Authentication Services....433
Manage vCenter Authentication Services Using the vSphere Client....434
Manage vCenter Authentication Services Using Scripts....434
Managing the vCenter....434
Manage vCenter Using the Management Interface....435
Manage vCenter Using the vCenter Shell....435
vSphere Security Certificates....435
vSphere Certificate Requirements for Different Solution Paths....436
vSphere Certificate Management....439
Replacing vSphere Certificates....440
Where vSphere Uses Certificates....443

VMware Certificate Authority and VMware Core Identity Services ... 445
VMware Endpoint Certificate Store ... 445
Managing vSphere Certificate Revocation ... 447
Replacing vSphere Certificates in Large Deployments ... 447
Managing Certificates Using the vSphere Client ... 448
Explore Certificate Stores Using the vSphere Client ... 448
Set the Threshold for vCenter Certificate Expiration Warnings Using the vSphere Client ... 449
Renew VMCA Certificates with New VMCA-Signed Certificates Using the vSphere Client ... 449
Replace Certificates with Custom Certificates Using the vSphere Client ... 450
Managing Certificates Using the vSphere Certificate Manager Utility ... 453
Regenerate a New VMCA Root Certificate and Replace All Certificates Using the Certificate Manager ... 454
Make VMCA an Intermediate Certificate Authority Using the Certificate Manager ... 455
Replace All Certificates with a Custom Certificate Using the Certificate Manager ... 458
Revert Last Performed Operation by Republishing Old Certificates Using the Certificate Manager ... 461
Reset All Certificates Using the Certificate Manager ... 461
Manual vSphere Certificate Replacement ... 462
Guidelines for Stopping and Starting of vCenter Services ... 462
Replace Existing VMCA-Signed Certificates with New VMCA-Signed Certificates Using the CLI ... 462
Make VMCA Into an Intermediate Certificate Authority Using the CLI ... 468
Replace Certificates with Custom Certificates Using the CLI ... 475
vSphere Certificates and Services CLI Command Reference ... 477
certool Initialization Commands Reference ... 479
certool Management Commands Reference ... 481
vecs-cli Command Reference ... 483
dir-cli Command Reference ... 487
vSphere Authentication with vCenter Single Sign-On ... 492
How vCenter Single Sign-On Protects Your Environment ... 493
vCenter Identity Provider Federation ... 496
How vCenter Identity Provider Federation Works ... 496
vCenter Identity Provider Federation Caveats and Interoperability ... 499
vCenter Identity Provider Federation Life Cycle ... 501
vCenter Identity Provider Federation and Enhanced Linked Mode ... 502
Activation Process for External Identity Providers in Enhanced Linked Mode Configurations ... 505
Configuring vCenter Identity Provider Federation ... 506
vCenter Identity Provider Federation Configuration Process Flow ... 506
Use the Trusted Root Certificates Store Instead of the JRE truststore ... 509
Configure vCenter Identity Provider Federation for AD FS ... 509
Configure vCenter Identity Provider Federation for Okta ... 512
Configure vCenter Identity Provider Federation for Microsoft Entra ID ... 514
Configuring vCenter Identity Provider for PingFederate ... 517
Configure VMware Single Sign-On ... 528
Managing VMware Identity Services ... 530
vCenter Single Sign-On ... 531

vCenter Single Sign-On Components 531
Using vCenter Single Sign-On with vSphere 532
Groups in the vCenter Single Sign-On Domain 533
Configuring vCenter Single Sign-On Identity Sources 535
Identity Sources for vCenter with vCenter Single Sign-On 535
Set the Default Domain for vCenter Single Sign-On 536
Managing the vCenter Security Token Service 536
Refresh a vCenter STS Certificate Using the vSphere Client 537
Import and Replace a vCenter STS Certificate Using the vSphere Client 538
Replace a vCenter STS Certificate Using the Command Line 539
View the Active vCenter STS Signing Certificate Chain Using the vSphere Client 540
Determine the Expiration Date of an LDAPS SSL Certificate Using the Command Line 540
Managing vCenter Single Sign-On Policies 540
Edit the vCenter Single Sign-On Password Policy 541
Edit the vCenter Single Sign-On Lockout Policy 542
Edit the vCenter Single Sign-On Token Policy 542
Managing vCenter Single Sign-On Users and Groups 543
Add vCenter Single Sign-On Users 543
Deactivate and Activate vCenter Single Sign-On Users 544
Delete a vCenter Single Sign-On User 545
Edit a vCenter Single Sign-On User 545
Add a vCenter Single Sign-On Group 546
Add Members to a vCenter Single Sign-On Group 546
Remove Members from a vCenter Single Sign-On Group 547
Change Your vCenter Single Sign-On Password 547
Managing the Login Message to the vSphere Client Login Page 548
Manage the Login Message to the vSphere Client Login Page 548
vCenter Single Sign-On Security Best Practices 549
Troubleshooting vCenter Authentication 549
Determining the Cause of a Lookup Service Error 549
vCenter Login Fails Because the User Account Is Locked 550
VMware Directory Service Replication Can Take a Long Time 550
Export a vCenter Support Bundle 551
vCenter Authentication Services Logs Reference 551
vCenter and Host Management 552
Main vSphere Concepts and Features 552
Basics of Virtualization 552
Physical Topology of a vSphere Data Center 552
Software Components of vSphere 553
Client Interfaces for vSphere 554
Managed Inventory Objects in vSphere 554
Advanced vCenter Components 556
vCenter Plug-Ins 556

Using the vSphere Client **557**
Use and Configure Your vSphere Client 557
Manage the Login Message to the vSphere Client Login Page 557
Configure the vSphere Client Timeout Value 558
Refresh Data in Your vSphere Client 558
Use the vSphere Client Inventory 558
Use the Global Inventory Lists Navigator 559
Inventory Keyboard Shortcuts in the vSphere Client 559
Sort Your vSphere Client Inventory 560
Use Quick Filters in vSphere Client Inventory 560
Use Advanced Filters in vSphere Client Inventory 561
Search Your vSphere Client Inventory 561
Export vSphere Inventory Lists 562
Manage vCenter Client Plug-Ins 563
Start, Stop, and Restart Services 565
How to Provide Feedback in the vSphere Client 565
Use the VCF Feature Requests Portal to Submit vSphere Feature Requests 566
Configuring the Customer Experience Improvement Program **566**
VMware Customer Experience Improvement Program 566
Join or Leave Customer Experience Improvement Program in vSphere Client 566
Organizing Your vSphere Inventory **567**
Create a vSphere Data Center 568
Create a Folder 568
Add a Host to a Folder or a Data Center 569
How Do You Create and Configure Clusters in the vSphere Client 569
Create a Cluster 570
Extend and Configure a Cluster by Using the Quickstart Workflow 571
Add a Host to a Cluster by Using the Quickstart Workflow 572
Configure a Cluster by Using the Quickstart Workflow 573
Extend a Cluster with Host Networking Configuration 575
Extend and Configure a Cluster Manually 576
vSphere Tags and Custom Attributes **577**
What Are vSphere Tags and How to Use Them 577
Create and Edit a Tag Category 578
Delete a Tag Category 579
Create and Edit a Tag 579
Delete a Tag 580
Use Advanced Filters to Filter Tags in the vSphere Client 580
Assign or Remove a Tag 581
Add Permissions for Tags and Tag Categories 581
vSphere Tagging Best Practices 582
Custom Attributes 582
Add and Edit Custom Attributes 582

vSphere Compute Policies **584**
Create a VM-Host Affinity Policy 585
Create a VM-Host Anti-Affinity Policy 587
Create a Limit VM Placement Span Plus One Host For Maintenance Policy 588
Create a VM Evacuation by Best Effort Restart on Best Host Policy 588
Create a VM-VM Affinity Policy 589
Create a VM-VM Anti-Affinity Policy 590
Working with vSphere Tasks **591**
View Tasks 591
Cancel a Task 591
Filter Tasks 592
Export Tasks 593
Export Tasks with Advanced Export 593
Scheduling vSphere Tasks 594
Create a Scheduled Task 595
Change or Reschedule a Scheduled Task 596
Remove a Scheduled Task 597
vSphere Host Configuration **597**
Configure the Boot Device on an ESX Host 597
Configure Agent VM Settings 598
Set Advanced Host Attributes 599
Advanced Memory Attributes 599
Advanced NUMA Attributes 600
Configuring the Time on Your ESX Host 601
Configure the Date and Time on Your ESX Host Manually 601
Use NTP Servers for Time and Date Synchronization of Your ESX Host 602
Use PTP for Time and Date Synchronization of Your ESX Host 603
Manage the NTP and PTP Service Status on Your ESX Host 604
Delete a Time Synchronization Service on Your ESX Host 604
Managing Hosts in the vSphere Client **604**
Disconnecting and Reconnecting an ESX Host 605
Disconnect a Managed Host 605
Reconnect a Managed Host 605
Reconnect Hosts After Changes to the vCenter SSL Certificate 606
Rename an ESX Host FQDN 606
Relocate a Host 606
Remove a Host from vCenter 607
Reboot or Shut Down an ESX Host 608
Verify SSL Certificates for Legacy Hosts 608
Enabling SGX Remote Attestation on Multi-Socket ESX Hosts 609
View the SGX Registration Status of a Host 609
Register a Multi-Socket ESX Host with the Intel SGX Registration Server 610
vSphere Virtual Machines Migration **610**

Cold Migration in Your vSphere Environment.... 611
Migrate a Powered Off or Suspended Virtual Machine....612
Hot Migration....615
Host Configuration for vSphere vMotion.... 615
Virtual Machine Conditions and Limitations for vSphere vMotion....618
Using vSphere vMotion to Migrate vGPU Virtual Machines....618
Set a Stun Time Limit for a vMotion Migration of a Virtual Machine with a PCI Device....622
Virtual Machines Swap File Location and vSphere vMotion Compatibility....624
vSphere vMotion Notifications for Latency Sensitive Applications....624
Migrate a Virtual Machine to a New Compute Resource....625
Migration with Storage vMotion.... 627
Migrate Your Virtual Machine to a New Compute Resource and Storage.... 629
vSphere vMotion in Environments Without Shared Storage.... 631
Migrating Virtual Machines Between vCenter Systems....632
Requirements for vMotion Between vCenter Instances....632
Network Compatibility Checks During vMotion Between vCenter Instances.... 633
MAC Address Management During Migration Between vCenter Systems.... 633
Export or Clone a Virtual Machine with Advanced Cross vCenter vMotion.... 633
Import or Clone a Virtual Machine with Advanced Cross vCenter vMotion.... 637
Migrating Virtual Machines Between Servers with DPU Devices....641
Encrypted vSphere vMotion....641
Activate Encrypted vMotion on a Virtual Machine....643
How to Isolate Traffic for Migrating Your Virtual Machines.... 643
Place vMotion Traffic on the vMotion TCP/IP Stack of a Host.... 643
Place Traffic for Cold Migration on the Provisioning TCP/IP Stack.... 645
vCenter Limits on Simultaneous Migrations....647
vMotion Migration Compatibility Checks....648

Edit a Link Aggregation Group....1148
Limitations of the LACP Support on a vSphere Distributed Switch....1149
Back Up and Restore Network Configurations....1149
Back Up and Restore a vSphere Distributed Switch Configuration....1149
Export vSphere Distributed Switch Configurations....1149
Import a vSphere Distributed Switch Configuration....1150
Restore a vSphere Distributed Switch Configuration....1151
Export, Import, and Restore vSphere Distributed Port Group Configurations....1151
Export vSphere Distributed Port Group Configurations....1151
Import a vSphere Distributed Port Group Configuration....1152
Restore a vSphere Distributed Port Group Configuration....1152
ESX Configuration Manager Integration....1153
Export Host Configuration....1153
Import Host Configuration....1154
Rollback and Recovery of the Management Network....1155
vSphere Networking Rollback....1155
Disable Network Rollback....1156
Disable Network Rollback by Using the vCenter Configuration File....1156
Resolve Errors in the Management Network Configuration on a vSphere Distributed Switch....1156
vSphere Networking Policies....1157
Apply Networking Policies on a vSphere Standard or Distributed Switch....1157
Configure Overriding Networking Policies on Port Level....1158
What is Teaming and Failover Policy....1158
Load Balancing Algorithms Available for Virtual Switches....1159
Configure NIC Teaming, Failover, and Load Balancing on a vSphere Standard Switch or Standard Port Group....1162
Configure NIC Teaming, Failover, and Load Balancing on a Distributed Port Group or Distributed Port....1164
What is VLAN Policy....1166
Configure VLAN Tagging on a Distributed Port Group or Distributed Port....1166
Configure VLAN Tagging on an Uplink Port Group or Uplink Port....1166
What is Security Policy....1167

Configure the Security Policy for a vSphere Standard Switch or Standard Port Group....1167
Configure the Security Policy for a Distributed Port Group or Distributed Port....1169
What is Traffic Shaping Policy....1170
Configure Traffic Shaping for a vSphere Standard Switch or Standard Port Group....1170
Edit the Traffic Shaping Policy on a Distributed Port Group or Distributed Port....1171
What is Resource Allocation Policy....1172
Edit the Resource Allocation Policy on a Distributed Port Group....1172
What is Traffic Filtering and Marking Policy....1172
Traffic Filtering and Marking on a Distributed Port Group or Uplink Port Group....1173
Traffic Filtering and Marking on a Distributed Port or Uplink Port....1177
Qualifying Traffic for Filtering and Marking....1182
Manage Policies for Multiple Port Groups on a vSphere Distributed Switch....1184
Port Blocking Policies....1187
Edit the Port Blocking Policy for a Distributed Port Group....1187
Edit the Blocking Policy for a Distributed Port or Uplink Port....1187
What is the MAC Learning Policy....1188
How to Use VLANs to Isolate Network Traffic....1188
VLAN Configuration....1188
Private VLANs....1189
Create a Private VLAN....1189
Remove a Primary Private VLAN....1190
Remove a Secondary Private VLAN....1190
Manage Network Resources....1190
DirectPath I/O....1190
Enable Passthrough for a Network Device on a Host....1191
Hot-add and Hot-remove support for VM DirectPath Devices....1192
Enable Hot-Add and Hot-Remove of VM DirectPath Devices....1193
Prepare and configure VM....1194
Verify If the Hot Plug Operation is Successful using vSphere Client....1194
Verify If the Hot Plug Operation is Successful using VM....1195
What is Single Root I/O Virtualization (SR-IOV)....1195
SR-IOV Support....1196
SR-IOV Component Architecture and Interaction....1197
vSphere and Virtual Function Interaction....1199
DirectPath I/O vs SR-IOV....1199
Configure a Virtual Machine to Use SR-IOV....1200
Networking Options for the Traffic Related to an SR-IOV Enabled Virtual Machine....1204
Using an SR-IOV Physical Adapter to Handle Virtual Machine Traffic....1204
Enable SR-IOV by Using Host Profiles or an ESXCLI Command....1205
What is Remote Direct Memory Access for Virtual Machines....1206
PVRDMA Support....1207
Configure an ESX Host for PVRDMA....1208
Assign a PVRDMA Adapter to a Virtual Machine....1208

Configure a Virtual Machine to Use PVRDMA Native Endpoints....1209
Configure a Virtual Machine to use PVRDMA Asynchronous Mode....1209
Network Requirements for RDMA over Converged Ethernet....1210
Configure Remote Direct Memory Access Network Adapters....1211
View RDMA Capable Network Adapter....1211
Configure Remote Direct Memory Access Network Adapters....1211
Capture RDMA Packets on an ESX Host....1213
Use rdmaperf to Validate and Evaluate RDMA Connectivity Between ESX Hosts....1214
What are Jumbo Frames....1216
Enable Jumbo Frames on a vSphere Distributed Switch....1216
Enable Jumbo Frames on a vSphere Standard Switch....1217
Enable Jumbo Frames for a VMkernel Adapter....1217
Enable Jumbo Frame Support on a Virtual Machine....1217
What is TCP Segmentation Offload....1218
Manage Software TSO in the VMkernel....1218
How to determine whether TSO is Supported on the Physical Network Adapters on an ESX Host....1218
Manage TSO on an ESX Host....1219
How to find if TSO Is Enabled on an ESX Host....1219
Manage TSO on a Linux Virtual Machine....1219
Manage TSO on a Windows Virtual Machine....1220
What is Large Receive Offload....1220
Manage Hardware LRO for All VMXNET3 Adapters on an ESX Host....1220
Manage Software LRO for All VMXNET3 Adapters on an ESX Host....1221
Determine Whether LRO Is Enabled for VMXNET3 Adapters on an ESX Host....1221
Change the Size of the LRO Buffer for VMXNET 3 Adapters....1221
Activate or Deactivate LRO for All VMkernel Adapters on an ESX Host....1221
Change the Size of the LRO Buffer for VMkernel Adapters....1222
Manage LRO on a VMXNET3 Adapter on a Linux Virtual Machine....1222
Manage LRO on a VMXNET3 Adapter on a Windows Virtual Machine....1222
Manage LRO Globally on a Windows Virtual Machine....1223
NetQueue and Networking Performance....1223
Activate NetQueue on a Host....1223
Deactivate NetQueue on a Host....1224
vSphere Network I/O Control....1224
What is vSphere Network I/O Control....1224
Enable Network I/O Control on a vSphere Distributed Switch....1224
Allocate Bandwidth for System Traffic....1225
Bandwidth Allocation Parameters for System Traffic....1225
Example of Bandwidth Reservation for System Traffic....1226
How to Allocate Bandwidth for System Traffic....1226
Allocate Bandwidth for Virtual Machine Traffic....1227
How to Allocate Bandwidth for Virtual Machines....1227
Bandwidth Allocation Parameters for Virtual Machine Traffic....1229

Admission Control for Virtual Machine Bandwidth.... 1229
Create a Network Resource Pool.... 1230
Add a Distributed Port Group to a Network Resource Pool.... 1231
Configure Bandwidth Allocation for a Virtual Machine.... 1231
Configure Bandwidth Allocation on Multiple Virtual Machines.... 1232
Modify the Quota of a Network Resource Pool.... 1233
Remove a Distributed Port Group from a Network Resource Pool.... 1233
Delete a Network Resource Pool.... 1233
Move a Physical Adapter Out of Network I/O Control.... 1234
MAC Address Management.... 1234
MAC Address Assignment from vCenter.... 1234
What is VMware OUI Allocation.... 1235
What is Prefix-Based MAC Address Allocation.... 1235
What is Range-Based MAC Address Allocation.... 1235
Assigning a MAC Address.... 1236
MAC Address Generation on ESX Hosts.... 1237
How to set a Static MAC Address to a Virtual Machine.... 1238
VMware OUI in Static MAC Addresses.... 1238
Assign a Static MAC Address.... 1239
Assign a Static MAC Address in the Virtual Machine Configuration File.... 1239
Configure vSphere for IPv6.... 1239
vSphere IPv6 Connectivity.... 1240
Deploy vSphere on IPv6.... 1241
Enable IPv6 on a vSphere Installation.... 1241
Enable IPv6 on an Upgraded vSphere Environment.... 1241
Activate or Deactivate IPv6 Support on a Host.... 1243
Set Up IPv6 on an ESX Host.... 1243
Set Up IPv6 on vCenter.... 1244
Monitor Network Connection and Traffic.... 1245
How to Capture Network Packets.... 1245
Capture and Trace Network Packets by Using the pktcap-uw Utility.... 1246
pktcap-uw Command Syntax for Capturing Packets.... 1246
pktcap-uw Command Syntax for Tracing Packets.... 1248
pktcap-uw Options for Output Control.... 1249
pktcap-uw Options for Filtering Packets.... 1249
Capturing Packets by Using the pktcap-uw Utility.... 1251
How to Trace Packets using the pktcap-uw Utility.... 1258
Configure the NetFlow Settings of a vSphere Distributed Switch.... 1259
What is Port Mirroring.... 1259
What is Port Mirroring Interoperability.... 1259
Create a Port Mirroring Session.... 1261
View Port Mirroring Session Details.... 1264
Edit Port Mirroring Session Details, Sources, and Destinations.... 1264

vSphere Distributed Switch Health Check....1265
Manage vSphere Distributed Switch Health Check....1266
View vSphere Distributed Switch Health Status....1266
Switch Discovery Protocol....1267
Enable Cisco Discovery Protocol on a vSphere Distributed Switch....1267
Enable Link Layer Discovery Protocol on a vSphere Distributed Switch....1267
View Switch Information....1268
Configure Protocol Profiles for Virtual Machine Networking....1268
Add a Network Protocol Profile....1269
Select the Network Protocol Profile Name and Network....1270
Specify Network Protocol Profile IPv4 Configuration....1270
Specify Network Protocol Profile IPv6 Configuration....1270
Specify Network Protocol Profile DNS and Other Configuration....1271
Complete the Network Protocol Profile Creation....1271
Associate a Port Group with a Network Protocol Profile....1271
What is Multicast Filtering....1272
Multicast FilterinBasic Multicast FilteringIn basic multicast filtering mog Modes....1272
Enable Multicast Snooping on a vSphere Distributed Switch....1273
Edit the Query Time Interval for Multicast Snooping....1273
Edit the Number of Source IP Addresses for IGMP and MLD....1273
What is Stateless Network Deployment....1273
vSphere Networking Best Practices....1274
Troubleshoot vSphere Networking....1275
Troubleshoot MAC Address Allocation....1275
Duplicate MAC Addresses of Virtual Machines on the Same Network....1275
Attempt to Power On a Virtual Machine Fails Due to a MAC Address Conflict....1277

Documentation Legal Notice..... 2298

Release Notes

Release notes include product enhancements and notices, bug fixes, and resolved issues.

For vSphere 9.1 release notes, read VMware Cloud Foundation 9.1.1 release notes.

For single host management release notes, read VMware Host Client 9.1 release notes.

vSphere Express

Learn how to deploy, upgrade, and license a vSphere Express environment.

Components in vSphere Express

The full functionality is implemented by a set of mandatory and optional components.

Mandatory components:

- ESX
- vCenter
- VCF Operations
- License server

Optional components:

- vSphere Replication (part of protection and recovery)
- VMware Tools
- VMware Remote Console

Deploying vSphere Express

You can build a fully operational environment by deploying and configuring components manually.

Table 1: Deployment Order

#	Component	Documentation
1	ESX	Deploy ESX Hosts
2	vCenter	Deploy vCenter
3	VCF Operations	Deploy VCF Operations
4	License server	Deploy a License Server
5	(Optional) vSphere Replication	Deploy Protection and Recovery
6	(Optional) VMware Tools	Installing VMware Tools
7	(Optional) VMware Remote Console	Installing VMware Remote Console

Upgrading from vSphere 8 to vSphere Express

To upgrade your vSphere 8.x and Aria Operations 8.x virtual infrastructure to a fully functional and licensed vSphere Express 9.1.1 and later, comply with the source versions of your existing components and follow the order of upgrade and deployment procedures.

Minimum required version for components to upgrade:

- vCenter Server 8.0
- ESXi 8.0
- (Optional) Aria Operations 8.18.6
- (Optional) vSphere Replication 9.0.2.2

Table 2: Upgrade Order

#	Component	Documentation
1	vSphere Replication	Converge or Upgrade to Protection and Recovery 9.1
2	Aria Operations	Deploy VCF Operations 9.1 or Upgrade Aria Operations 8.18 and later
3	License server	Deploy a License Server
4	vCenter	Upgrade the vCenter Instance
5	ESX	Upgrade the ESX Hosts
6	vSphere Distributed Switch	Upgrade vSphere Distributed Switches
7	VMware Tools	Upgrade VMware Tools to 13.1
8	Virtual machine compatibility	Upgrade Virtual Machines

Converging vSphere Express to VCF

You can use your existing vSphere Express virtual infrastructure as building blocks to converge it to a full VCF deployment. See Converge a vCenter Instance, ESX Hosts, VMware Aria Operations.

Extending to vSphere Foundation

You can extend your existing vSphere Express virtual infrastructure to a vSphere Foundation environment by applying the respective license and optionally deploy VCF management services. See Deploy VCF Management Services for vSphere Foundation.

Licensing vSphere Express

vSphere Express uses the same licensing infrastructure as VMware Cloud Foundation and vSphere Foundation with some restrictions to license management functions.

You purchase a subscription, a default primary license appears in the VCF Business Services console, you add a license to VCF Operations and the license server, and you assign the license to assets by using VCF Operations. To license vSphere Express, you use this workflow with some restrictions on maximum license capacity, VCF Operations capabilities, and license management operations.

The following restrictions apply to vSphere Express.

License capacity maximum	A maximum of 128 cores per customer. The VCF Business Services console prevents any allocation that exceeds 128 cores per customer or site ID.
Default license only	You use only the default license to license your environment. You cannot split the default license into smaller licenses. You cannot share the default license across sites.
VCF Operations for licensing	With vSphere Express, you use VCF Operations only for licensing your environment.
You cannot use add-on licenses	No add-ons are available for vSphere Express.
Version 8 license keys are not available	vSphere Express is only available for version 9 or later.

For more information about the licensing model and how to manage and assign licenses, see the VCF Licensing guide.

vSphere Features in vSphere Express

vSphere Express entitles you to certain vSphere features. For more information on vSphere Express features, consult your sales representative.

ESX Installation and Setup

VMware ESX Installation and Setup describes how to install and configure VMware ESX™.

At VMware, we value inclusion. To foster this principle within our customer, partner, and internal community, we have updated this guide to remove instances of non-inclusive language.

Intended Audience

VMware ESX Installation and Setup is intended for experienced administrators who want to install and configure ESX.

This information is written for experienced Windows or Linux system administrators who are familiar with virtual machine technology and data center operations. The information about using the Image Builder and VMware vSphere®Auto Deploy™ is written for administrators who have experience with Microsoft PowerShell and VMware Cloud Foundation® PowerCLI™.

In this guide, see:

- Installing and Setting Up ESX
- What is VMware vSphere Distributed Services Engine
- Customizing Installations with vSphere ESX Image Builder
- Installing ESX
- Setting Up ESX
- Troubleshooting ESX Booting
- Decommission an ESX Host

Installing and Setting Up ESX

See how install and set up ESX on your physical hardware so that it acts as a platform for virtual machines.

The two core components of vSphere are ESX and vCenter. ESX is the virtualization platform on which you can create and run virtual machines and virtual appliances. vCenter is a service that acts as a central administrator for ESX hosts connected in a network. vCenter lets you pool and manage the resources of multiple hosts. For detailed information about the vCenter deployment process, see vCenter Deployment and Setup.

In this guide, see how to install and set up ESX. Start with How to Install ESX and follow up with:

- Preparing for Installing ESX
- ESX Requirements
- Installing ESX
- Setting Up ESX
- After You Install and Set Up ESX

How to Install ESX

ESX is the virtualization platform on which you can create and run virtual machines and virtual appliances.

ESX 9.1 and later provides various options for installation and setup that define a corresponding sequence of tasks, but the basic sequence is as follows:

- Read the release notes for ESX 9.1 and later.
- Verify that your system meets the minimum hardware requirements. See ESX Requirements.
  Determine the ESX installation option to use: interactive, scripted or by using vSphere Auto Deploy.

  Attention:

  You can provision ESX hosts by using vSphere Auto Deploy, but Auto Deploy is installed together with vCenter, which is the service that acts as a central administrator for ESX hosts connected in a network. vCenter lets you pool and manage the resources of multiple hosts.

Determine where you want to locate and boot the ESX installer. See Media Options for Booting the ESX Installer If you are using PXE to boot the installer, verify that your network PXE infrastructure is properly set up. See Network Booting the ESX Installer.

Create a worksheet with the information you will need when you install ESX. See Required Information for ESX Installation.

Read and consider the General ESX Security Recommendations.

- Install ESX:
  - Install ESX Interactively
  - Scripted Installation
  - Installing ESX Using vSphere Auto Deploy
- Configure the ESX boot and network settings, the direct console, and other settings. See Setting Up ESX and After You Install and Set Up ESX.
- Consider setting up a syslog server for remote logging, to ensure sufficient disk storage for log files. Setting up logging on a remote host is especially important for hosts with limited local storage. See Required Free Space for System Logging and Configure Syslog on ESX Hosts.
- You deploy the vCenter appliance, a preconfigured virtual machine optimized for running vCenter and the vCenter components. You can deploy the vCenter appliance on ESX hosts or on vCenter instances. For detailed information about the vCenter installation process, see vCenter Installation and Setup.

About ESX Evaluation and Licensed Modes

Starting with ESX 9.0, you no longer license ESX hosts by using the vSphere Client. For more information on how to license your environment, see Licensing Overview in the *Licensing* guide.

The evaluation period is 90 days and begins when you turn on the ESX hosts, except for hosts that you provision by using Auto Deploy as stateless hosts. Such hosts have no evaluation period because booting ESX hosts by network with in-memory or cached images, preserving no state, was deprecated in ESX 9.0.

Preparing for Installing ESX

Before you install ESX, determine the installation option that is suitable for your environment and prepare for the installation process.

- To get started with ESX installation, you first need to read:
  - Download the ESX Installer
  - Required Information for ESX Installation
  - Media Options for Booting the ESX Installer

Download the ESX Installer

You can obtain the ESX installer software either from an OEM or from the Broadcom Support Portal.

Register for an account on the Broadcom Support Portal. For more information, see Broadcom knowledge base article 145581.

1. For product download instructions, see Broadcom knowledge base article 142814.
2. For download of offline bundle ZIP files for ESX patches and updates, see Broadcom knowledge base article 194106.
3. For more information, see Broadcom knowledge base article 278681.

Required Information for ESX Installation

Interactive installation prompts you for the required system information, but you must supply this information in the installation script.

In an interactive installation, the system prompts you for the required system information. In a scripted installation, you must supply this information in the installation script. For future use, note the values you use during the installation. These notes are useful if you must reinstall ESX and reenter the values that you originally selected.

Table 3: Required Information for ESX Installation

Information	Required or Optional	Default	Comments
Keyboard layout	Required	U.S. English	
VLAN ID	Optional	None	Range: 0 through 4095
IP address	Optional	DHCP	You can allow DHCP to configure the network during installation. After installation, you can change the network settings.
Subnet mask	Optional	Calculated based on the IP address	
Gateway	Optional	Based on the configured IP address and subnet mask	
Primary DNS	Optional	Based on the configured IP address and subnet mask	
Secondary DNS	Optional	None	
Host name	Required for static IP settings	None	The vSphere Client can use either the host name or the IP address to access the ESX host.
Install location	Required	None	Must be at least 8 GB if you install the components on a single disk.
Root password	Required	None	The root password must contain between 8 and 40 characters. For information about passwords see the *vSphere Security* documentation.

Media Options for Booting the ESX Installer

The installer must be accessible to the system on which you are installing ESX.

The following boot media are supported for the ESX installer:

- Boot from a CD/DVD. See Download and Burn the ESX Installer ISO Image to a CD or DVD.
- Boot from a USB flash drive. See Format a USB Flash Drive to Boot the ESX Installation or Upgrade.
- Boot from a network. See Network Booting the ESX Installer.
- Boot from a remote location using a remote management application. See Using Remote Management Applications.

Download and Burn the ESX Installer ISO Image to a CD or DVD

If you do not have an ESX installation CD/DVD, you can create one.

You can also create an installer ISO image that includes a custom installation script. See Create an Installer ISO Image with a Custom Installation or Upgrade Script.

1. Burn the ISO image to a CD or DVD.
2. Follow the procedure Preparing for Installing ESX.

Format a USB Flash Drive to Boot the ESX Installation or Upgrade

You can format a USB flash drive to boot the ESX installation or upgrade.

- Linux machine with superuser access to it.
- USB flash drive that can be detected by the Linux machine.
- The ESX ISO image, `VMware-VMvisor-Installer-`*`version_number-build_number`*`.x86_64.iso`, which includes the `isolinux.cfg` file.

The instructions in this procedure assume that the USB flash drive is detected as `/dev/sdb`.

Note:
The `ks.cfg` file that contains the installation script cannot be located on the same USB flash drive that you are using to boot the installation or upgrade. The kickstart file does not have any dependency on BIOS or UEFI boot.

1. Boot Linux, log in, and enter superuser mode by using a `su` or `sudo root` command.
2. If your USB flash drive is not detected as `/dev/sdb`, or you are not sure how your USB flash drive is detected, determine how it is detected.
   a) Plug in your USB flash drive.
   b) At the command line, run the command for displaying the current log messages.

      ```
      tail -f /var/log/messages
      ```

      You see several messages that identify the USB flash drive in a format similar to the following message.

      ```
      Oct 25 13:25:23 ubuntu kernel: [  712.447080] sd 3:0:0:0: [sdb] Attached SCSI
       removable disk
      ```

      In this example, `sdb` identifies the USB device. If your device is identified differently, use that identification in place of *`sdb`*.
3. Overwrite the entire USB drive with the ISO image. This operation overwrites the partition table and any previous content on the USB drive.

   ```
   dd bs=10M if=VMware-VMvisor-Installer-version_number-build_number.x86_64.iso of=/dev/
   sdb
   ```
4. Eject the USB drive.

   ```
   eject /dev/sdb
   ```

You can use the USB flash drive to boot the ESX installer.

Create a USB Flash Drive to Store the ESX Installation Script or Upgrade Script

You can use a USB flash drive to store the ESX installation script or upgrade script that is used during scripted installation or upgrade of ESX.

- Linux machine.
- ESX installation or upgrade script, the `ks.cfg` kickstart file.
- USB flash drive.

When multiple USB flash drives are present on the installation machine, the installation software searches for the installation or upgrade script on all attached USB flash drives.

The instructions in this procedure assume that the USB flash drive is detected as `/dev/sdb`.

Note:
Do not store the `ks` file containing the installation or upgrade script on the same USB flash drive that you are using to boot the installation or upgrade.

1. Attach the USB flash drive to a Linux machine that has access to the installation or upgrade script.
2. Create a partition table.

   ```
   /sbin/fdisk /dev/sdb
   ```
   a) Type `d` to delete partitions until they are all deleted.
   b) Type `n` to create primary partition 1 that extends over the entire disk.
   c) Type `t` to set the type to an appropriate setting for the FAT32 file system, such as `c`.
   d) Type `p` to print the partition table.

      The result should be similar to the following text:

      ```
      Disk /dev/sdb: 2004 MB, 2004877312 bytes
      255 heads, 63 sectors/track, 243 cylinders
      Units = cylinders of 16065 * 512 = 8225280 bytes
         Device Boot      Start         End      Blocks   Id  System
      ```

```
/dev/sdb1            1          243      1951866   c   W95 FAT32 (LBA)
```

e) Type `w` to write the partition table and quit.

3. Format the USB flash drive with the FAT32 file system.

   ```
   /sbin/mkfs.vfat -F 32 -n USB /dev/sdb1
   ```

4. Create a destination directory and mount the USB flash drive to it.

   ```
   mkdir -p /usbdisk
   mount /dev/sdb1 /usbdisk
   ```

5. Copy the ESX installation script to the USB flash drive.

   ```
   cp ks.cfg /usbdisk
   ```

6. Unmount the USB flash drive.

   ```
   umount /usbdisk
   ```

The USB flash drive contains the installation or upgrade script for ESX.

When you boot the ESX installer, point to the location of the USB flash drive for the installation or upgrade script. See Enter Boot Options to Run an Installation or Upgrade Script and PXELINUX Configuration Files.

Create an Installer ISO Image with a Custom Installation or Upgrade Script

You can customize the standard ESX installer ISO image with your own installation or upgrade script. This customization enables you to perform a scripted, unattended installation or upgrade when you boot the resulting installer ISO image.

- Linux machine.
- The ESX ISO image `VMware-VMvisor-Installer-x.x.x-XXXXXX.x86_64.iso`, where *x.x.x* is the version of ESX you are installing, and *XXXXXX* is the build number of the installer ISO image.
- Your custom installation or upgrade script, the `KS_CUST.CFG` kickstart file.

See also Installing ESX by Using a Script and About the boot.cfg File .

1. Download the ESX ISO image from the Broadcom Support Portal.
2. Mount the ISO image in a folder.

   ```
   mount -o loop VMware-VMvisor-Installer-x.x.x-XXXXXX.x86_64.iso /esx_cdrom_mount
   ```

   `XXXXXX` is the ESX build number for the version that you are installing or upgrading to.

3. Copy the contents of `esx_cdrom` to another folder.

   ```
   cp -r /esx_cdrom_mount/* /esx_cdrom
   ```

4. Copy the kickstart file to `/esx_cdrom`.

   ```
   cp KS_CUST.CFG /esx_cdrom
   ```

5. Modify the `boot.cfg` file in both `/esx_cdrom/efi/boot/boot.cfg` (for UEFI boot) and `/esx_cdrom/boot.cfg` (for legacy BIOS boot) to specify the location of the installation or upgrade script by using the `kernelopt` option.

   You must use uppercase characters to provide the path of the script, for example,

   ```
   kernelopt=runweasel ks=cdrom:/KS_CUST.CFG
   ```

   The installation or upgrade becomes completely automatic, without the need to specify the kickstart file during the installation or upgrade.

6. Recreate the ISO image using the `mkisofs` or the `genisoimage` command.

Command	Syntax
mkisofs	`mkisofs -relaxed-filenames -J -R -o custom_esx.iso -b ISOLINUX.BIN -c BOOT.CAT -no-emul-boot -boot-load-size 4 -boot-info-table -eltorito-alt-boot -eltorito-platform efi -b EFIBOOT.IMG -no-emul-boot /esx_cdrom`

Command	Syntax
genisoimage	`genisoimage -relaxed-filenames -J -R -o custom_esx.iso -b ISOLINUX.BIN -c BOOT.CAT -no-emul-boot -boot-load-size 4 -boot-info-table -eltorito-alt-boot -e EFIBOOT.IMG -no-emul-boot /esx_cdrom`

You can use this ISO installer image for regular boot or UEFI secure boot. However, the vSphere Lifecycle Manager cannot verify the checksum of such an ISO image and you cannot use it for upgrades by using vSphere Lifecycle Manager workflows.

The ISO image includes your custom installation or upgrade script.

Install ESX from the ISO image.

ESX Requirements

To install or upgrade ESX, your system must meet specific hardware and software requirements.

See the full list of ESX requirements:

- ESX System Storage Overview
- ESX Hardware Requirements
- Using Remote Management Applications
- Recommendations for Enhanced ESX Performance
- Incoming and Outgoing Firewall Ports for ESX Hosts
- Required Free Space for System Logging
- VMware Host Client System Requirements
- ESX Passwords and Account Lockout

ESX System Storage Overview

ESX 9.1 and later has a system storage layout that allows flexible management of partitions and third-party components, while facilitating debugging.

ESX System Storage

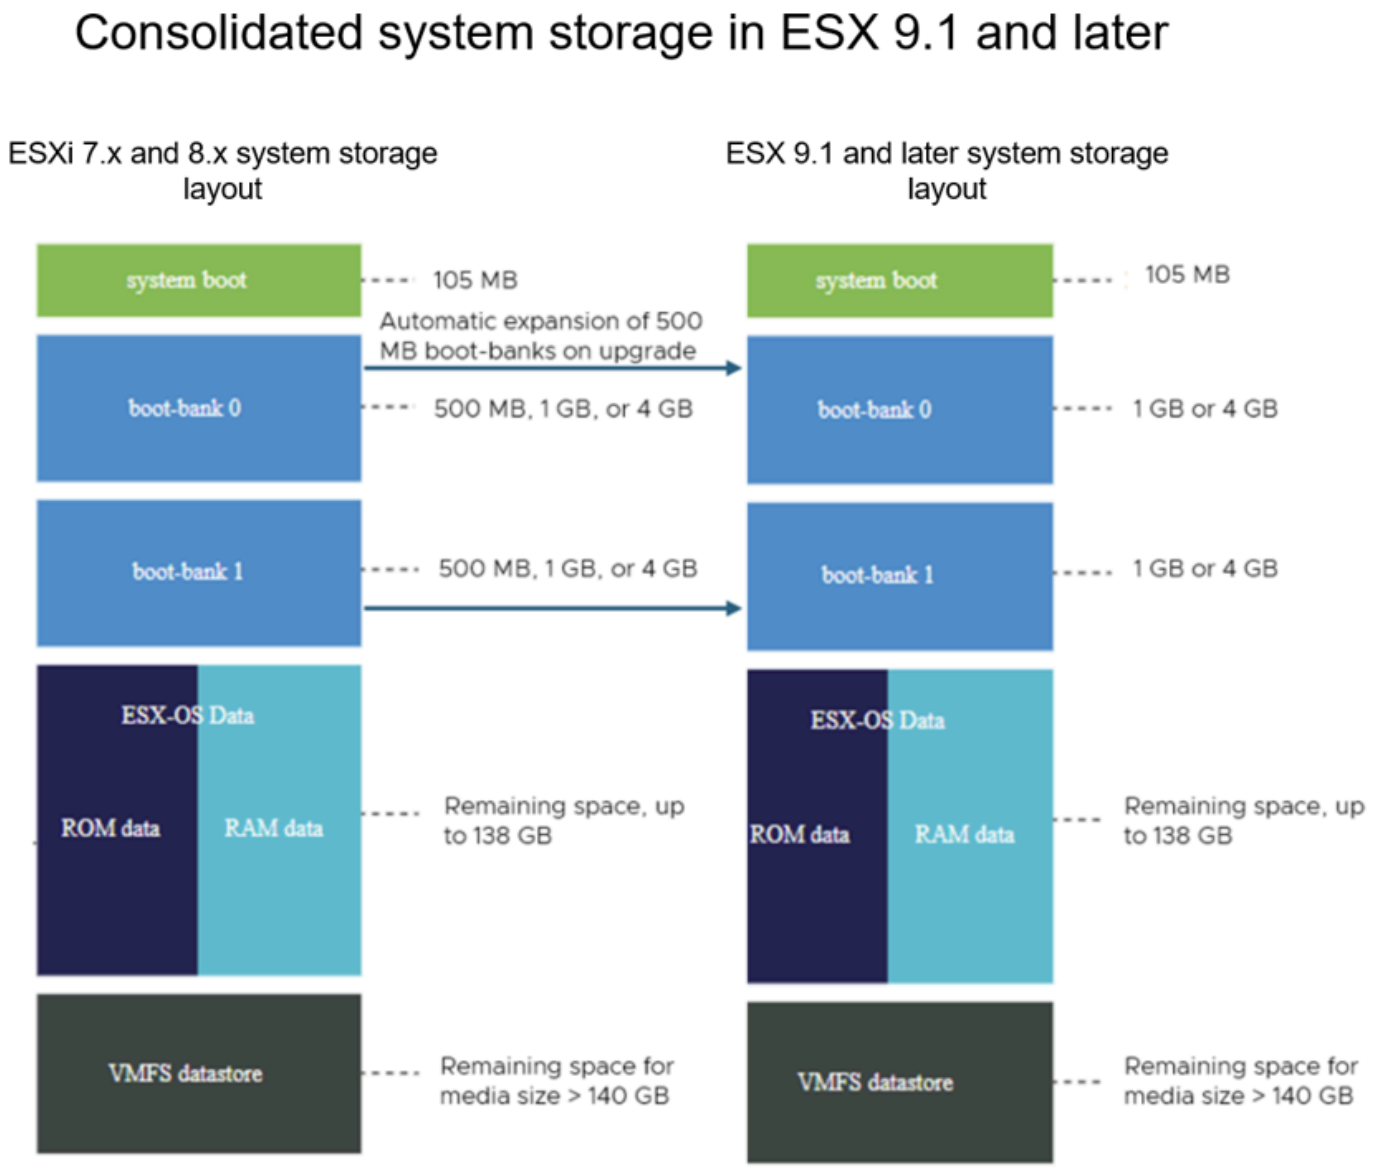
The ESX 9.1 and later system storage layout consists of four partitions:

Table 4: ESX system storage partitions:

Partition	Use	Type
System Boot	Stores boot loader and EFI modules.	FAT16
Boot-bank 0	System space to store ESX boot modules.	FAT16
Boot-bank 1	System space to store ESX boot modules.	FAT16
ESX-OSData	Acts as the unified location to store additional modules. Not used for booting and virtual machines. Consolidates the legacy `/scratch` partition, locker partition for VMware Tools, and core dump destinations. **CAUTION:** In case the installation media is a USB or an SD card device, best practice is to create ESX-OSData partitions on persistent storage device that is not shared between ESX hosts.	VMFS-L

The ESX-OSData volume is divided into two high-level categories of data, persistent and non-persistent data. Persistent data contains of data written infrequently, for example, VMware Tools ISOs, configurations, and core dumps.

Non-persistent data contains of frequently written data, for example, logs, VMFS global traces, vSAN Entry Persistence Daemon (EPD) data, vSAN traces, and real-time databases.



ESX System Storage Sizes

Partition sizes, except for the system boot partition, can vary depending on the size of the boot media used. If the boot media is a high-endurance one with capacity larger than 140 GB, a VMFS datastore is created automatically to store virtual machine data.

You can review the boot media capacity and the automatic sizing as configured by the ESX installer by using the vSphere Client and navigating to the **Partition Details** view. Alternatively, you can use ESXCLI, for example the `esxcli storage filesystem list` command.

Table 5: ESX System Storage Sizes, Depending on the Used Boot Media and Its Capacity.

Boot Media Size	8-32 GB	32-128 GB	>128 GB
System Boot	~ 105 MB	~ 105 MB	~ 105 MB
Boot-bank 0	~ 1 GB	~ 4 GB	~ 4 GB
Boot-bank 1	~ 1 GB	~ 4 GB	~ 4 GB
ESX-OSData	remaining space	remaining space	up to 138 GB
VMFS datastore			remaining space for media size > 140 GB

You can use the ESX installer boot option `systemMediaSize` to increase the size of system storage partitions on the boot media. The `systemMediaSize` parameter accepts the following values:

- default (138 GB)
- max (consume all available space, for multi-terabyte servers)

To set the boot option at install time, refer to Enter Boot Options to Run an Installation or Upgrade Script. For more information, see Broadcom knowledge base article 345195.

ESX System Storage Links

The sub-systems that require access to the ESX partitions, access these partitions by using the following symbolic links:

Table 6: ESX system storage symbolic links.

System Storage Volume	Symbolic Link
Boot-bank 0	`/bootbank`
Boot-bank 1	`/altbootbank`

Persistent data	`/productLocker`
	`/locker`
	`/var/core`
	`/usr/lib/vmware/isoimages`
	`/usr/lib/vmware/floppies`

Non-persistent data	`/var/run`
	`/var/log`
	`/var/vmware`
	`/var/tmp`
	`/scratch`

Storage Behavior

When you start ESX, the host enters an autoconfiguration phase during which system storage devices are configured with defaults.

When you reboot the ESX host after installing the ESX image, the host configures the system storage devices with default settings. Starting with ESX 7.0, you can activate the option autoPartition, which automatically formats all available empty devices with VMFS, except for legacy SD and USB devices. The default is `autoPartition=FALSE`, which formats with VMFS only boot devices with size larger than 140 GB. For more information, see Broadcom knowledge base article 313264.

> **CAUTION:**
> ESX overwrites any disks that appear to be blank. Disks are considered to be blank if they do not have a valid partition table or partitions. If you are using software that uses such disks, in particular if you are using logical

volume manager (LVM) instead of, or in addition to, conventional partitioning schemes, ESX might cause local LVM to be reformatted. Back up your system data before you power on ESX for the first time.

On the hard drive or USB device that the ESX host is booting from, the disk-formatting software retains existing diagnostic partitions that the hardware vendor creates. In the remaining space, the software creates the partitions described below.

Partitions Created by ESX on the Host Drive

For fresh installations, several new partitions are created for the system boot, boot banks, and ESX-OSData. Fresh ESX installations use GUID Partition Tables (GPT) instead of MSDOS-based partitioning. The installer creates boot banks of varying size depending on the size of the disk. For more information on the scratch partition see About the Scratch Partition.

The installer affects only the installation disk. The installer does not affect other disks of the server. When you install on a disk, the installer overwrites the entire disk. When the installer autoconfigures storage, the installer does not overwrite hardware vendor partitions.

To create the VMFS datastore, the ESX installer requires a minimum of 140 GB of free space on the installation disk.

You might want to override this default behavior if, for example, you use shared storage devices instead of local storage. To prevent automatic disk formatting, detach the local storage devices from the host under the following circumstances:

- Before you start the host for the first time.
- Before you start the host after you reset the host to the configuration defaults.

To override the VMFS formatting if automatic disk formatting already occurred, you can remove the datastore.

Upgrade on Systems with Existing 500 MB Boot-banks

Starting with ESX 9.0, boot-banks on the boot disk can only be 1 GB or 4 GB. For systems with existing 500 MB boot-banks, the upgrade process to ESX 9.1 or later automatically repartitions the boot device to create 1 GB boot-banks.

The following events occur during the repartitioning process:

- Existing 500 MB boot banks expand to ~1GB.
- The ESX-OSData volume is reduced by ~1 GB.
- Some non-critical system data might be lost.

Important:

Rollback from ESX 9.1 to 8.x is not possible in these cases due to the repartitioning process of the boot device. Rollback from ESX 9.1 to 8.x is possible as long as no changes to the bootbank partitions have been made and no corrupt partition is detected.

About the Scratch Partition

For new installations of ESX, during the autoconfiguration phase, a scratch partition is created as part of the ESX-OSData partition.

The scratch partition serves to store system logs, which you need when you create a support bundle. If the scratch partition is not present, system logs are stored in a ramdisk. If no scratch partition is created, you can configure one. You can also override the default configuration.

You can create the scratch partition on a remote SAN or NFS-mounted directory.

Set the Scratch Partition from the vSphere Client

If a scratch partition is not set up, you might want to configure one, especially if the host is low on memory. When a scratch partition is not present, system logs are stored in a ramdisk.

The directory to use for the scratch partition must exist on the host.

1. From the vSphere Client, connect to vCenter.
2. Select the ESX host in the inventory.
3. Click the **Configure** tab.
4. Select **System**.
5. Select **Advanced System Settings**.
   The setting **ScratchConfig.CurrentScratchLocation** shows the current location of the scratch partition.
6. In the **ScratchConfig.ConfiguredScratchLocation** text box, enter a directory path that is unique for this host. For example, `/vmfs/volumes/DatastoreUUID/DatastoreFolder`.
7. Reboot the host for the changes to take effect.

ESX Hardware Requirements

Make sure that the ESX host meets the minimum hardware configurations supported by ESX 9.1 and later.

Hardware and System Resources

Note:

Starting with VCF 9.1, support is deprecated and will be removed in the next major release for the following:

- USB and SD boot devices.
- ESX without a persistent system storage device for OSDATA partition.
- ESX with system storage device of less than 32 GB.
- APIs for reconfiguring the system storage locations.

To install or upgrade ESX, your hardware and system resources must meet the following requirements:

- Supported server platform. For a list of supported platforms, see the Broadcom Compatibility Guide.
- ESX 9.1 and later requires a host with at least two CPU cores.
- ESX 9.1 and later supports a broad range of multi-core 64-bit x86 processors. For a complete list of supported processors, see the Broadcom Compatibility Guide.
- ESX 9.1 and later requires the NX/XD bit to be enabled for the CPU in the BIOS.
- ESX 9.1 and later requires a minimum of 8 GB of physical RAM. Provide at least 12 GB of RAM to run virtual machines in typical production environments.
- To support 64-bit virtual machines, support for hardware virtualization (Intel VT-x or AMD RVI) must be enabled on x64 CPUs.
- One or more Gigabit or faster Ethernet controllers. For a list of supported network adapter models, see the Broadcom Compatibility Guide.
- ESX 9.1 and later requires a boot disk of at least 32 GB of persistent storage such as HDD, SSD, or NVMe. A boot device must not be shared between ESX hosts.
- SCSI disk or a local, non-network, RAID LUN with unpartitioned space for the virtual machines.
- For Serial ATA (SATA), a disk connected through supported SAS controllers or supported on-board SATA controllers. SATA disks are considered remote, not local. These disks are not used as a scratch partition by default because they are seen as remote.

Storage Systems

For a list of supported storage systems, see the Broadcom Compatibility Guide.

ESX Booting Requirements

- In ESX 9.1and later, support for legacy BIOS is limited and booting ESX hosts from the Unified Extensible Firmware Interface (UEFI) is recommended. For more information on Broadcom plans to deprecate support for legacy BIOS in server platforms, see Deprecation of legacy BIOS support in vSphere.

- With UEFI, you can boot systems from hard drives, CD-ROM drives, or USB media. vSphere Auto Deploy supports network booting and provisioning of ESX hosts with UEFI.
- If your system has supported Data Processing Units (DPU), you can only use UEFI to install and boot ESX on the DPUs.
- If the system firmware and the firmware on any add-in card that you are using support it, ESX can boot from a disk larger than 2 TB. See the vendor documentation.

Storage Requirements for ESX 9.1 Installation or Upgrade

For best performance of an ESX 9.1 installation, when deploying new servers, use a persistent storage device that is a minimum of 128 GB for boot devices. Upgrading servers with boot disk of size less than 8 GB to ESX 9.1 is blocked.

Note:

In ESX 9.1, the ESX-OSData volume is considered a unified partition and the separate components, such as `/scratch` and VMware Tools, are consolidated into a single persistent OSDATA partition.

Other options for best performance of an ESX 9.1 installation are the following:

- A persistent storage device that supports the minimum of 128 TB written (TBW).
- A device that delivers at least 100 MB/s of sequential write speed.
- To provide resiliency in case of device failure, a RAID 1 mirrored device is recommended.

Legacy SD and USB devices are supported with the following limitations:

- SD and USB devices are supported for boot bank partitions. The use of SD and USB devices for storing ESX-OSData partitions is being deprecated and best practice is to provide a separate persistent local device with a minimum of 128 GB to store the ESX-OSData volume. The persistent local boot device can be an industrial grade M.2 flash (SLC and MLC), SAS, SATA, HDD, SSD, or a NVMe device.
- If you do not provide persistent storage, you see an alarm such as `Secondary persistent device not found. Please move installation to persistent storage as support for SD-Card/USB only configuration is being deprecated`.
- You must use an SD flash device that is approved by the server vendor for the particular server model on which you want to install ESX on an SD flash storage device. You can find a list of validated devices in the Broadcom Compatibility Guide.
- See SD card/USB boot device revised guidance on updated guidance for SD card or USB-based environments.

If you use USB or SD devices to perform an upgrade, best practice is to allocate an ESX-OSData region on an available persistent disk or a SAN LUN. If persistent storage or a SAN LUN are not available, ESX-OSData is automatically created on a RAM disk. VMFS can also be used for ESX-OSData partition.

After upgrade, if ESX-OSData resides on a RAM disk and a new persistent device is found on subsequent boots, and this device has the setting `autoPartition=True`, ESX-OSData is automatically created on the new persistent device. ESX-OSData does not move between persistent storage automatically, but you can manually change the ESX-OSData location on a supported storage.

To reconfigure `/scratch`, see Set the Scratch Partition from the vSphere Client.

To configure the size of ESX system partitions, you can use the `systemMediaSize` option. For more information, see Boot option to configure the size of ESX system partitions.

In vSphere Auto Deploy installations, the installer attempts to allocate a scratch region on an available local disk or datastore. If no local disk or datastore is found, installation fails.

For environments that boot from a SAN or use vSphere Auto Deploy, the ESX-OSData volume for each ESX host must be set up on a separate SAN LUN.

Using Remote Management Applications

Remote management applications allow you to install ESX on servers that are in remote locations.

Remote management applications supported for installation include HP Integrated Lights-Out (iLO), Dell Remote Access Card (DRAC), IBM management module (MM), Fujitsu iRMC, and Remote Supervisor Adapter II (RSA II). For support on remote management applications, contact the vendor.

You can use remote management applications to do both interactive and scripted installations of ESX remotely.

If you use remote management applications to install ESX, the virtual CD might encounter corruption problems with systems or networks operating at peak capacity. If a remote installation from an ISO image fails, complete the installation from the physical CD media.

Supported Remote Management Server Models and Firmware Versions

You can use remote management applications to install or upgrade ESX, or to manage hosts remotely.

Table 7: Supported Remote Management Server Models and Minimum Firmware Versions

Remote Management Server Model	Firmware Version	Java
Dell DRAC 10	1.10.17.00	N/A
Dell DRAC 9	6.0.30.00	N/A
Dell DRAC 7	1.30.30 (Build 43)	1.7.0_60-b19
Dell DRAC 6	1.54 (Build 15), 1.70 (Build 21)	1.6.0_24
Dell DRAC 5	1.0, 1.45, 1.51	1.6.0_20,1.6.0_203
Dell DRAC 4	1.75	1.6.0_23
Fujitsu iRMC S5	1.10P	1.7.0_60-b19
Fujitsu iRMC S6	1.06S	N/A
HP ILO	1.81, 1.92	1.6.0_22, 1.6.0_23
HP ILO 2	1.8, 1.81	1.6.0_20, 1.6.0_23
HP ILO 3	1.28	1.7.0_60-b19
HP ILO 4	1.13	1.7.0_60-b19
HP ILO 5	2.72	N/A
HPE ILO 6	1.10	N/A
HPE ILO 7	1.20	N/A
IBM RSA 2	1.03, 1.2	1.6.0_22
Lenovo XClarity Controller 2 (XCC2)	8.10 (iyx346k-8.10)	N/A
Lenovo XClarity Controller 3 (XCC3)	9.11 (qgx3a2g-9.11)	N/A

Recommendations for Enhanced ESX Performance

To enhance performance, install or upgrade ESX on a robust system with more RAM than the minimum required and with multiple physical disks.

For ESX system requirements, see ESX Hardware Requirements.

Table 8: Recommendations for Enhanced Performance

System Element	Recommendation
RAM	ESX hosts require more RAM than typical servers. ESX 9.1 requires a minimum of 8 GB of physical RAM. Provide at least 12 GB of RAM to take full advantage of ESX features and run virtual machines in typical production environments. An ESX host must have sufficient RAM to run concurrent virtual machines. For possible memory savings from using variable overhead memory for each virtual machine, see *vSphere Resource Management*.
Dedicated Fast Ethernet adapters for virtual machines	Place the management network and virtual machine networks on different physical network cards. Dedicated Gigabit Ethernet cards for virtual machines, such as Intel PRO 1000 adapters, improve throughput to virtual machines with high network traffic.
Disk location	Place all data that your virtual machines use on physical disks allocated specifically to virtual machines. Performance is better when you do not place your virtual machines on the disk containing the ESX boot image. Use physical disks that are large enough to hold disk images that all the virtual machines use.
VMFS6 partitioning	The ESX installer creates the initial VMFS volumes on the first blank local disk found. To add disks or modify the original configuration, use the vSphere Client. This practice ensures that the starting sectors of partitions are 64K-aligned, which improves storage performance. **Note:** For SAS-only environments, the installer might not format the disks. For some SAS disks, it is not possible to identify whether the disks are local or remote. After the installation, you can use the vSphere Client to set up VMFS.
Processors	Faster processors improve ESX performance. For certain workloads, larger caches improve ESX performance.
Hardware compatibility	Use devices in your server that are supported by ESX drivers. See the Broadcom Compatibility Guide.

Required Free Space for System Logging

See the recommended minimum size and rotation configuration for hostd, vpxa, and fdm logs.

If you use Auto Deploy to install your ESX 9.1 host, or if you set up a log directory separate from the default location in a scratch directory on the VMFS volume, you might need to change your current log size and rotation settings to ensure that enough space is available for system logging. All vSphere components use this infrastructure. The default values for log capacity in this infrastructure vary, depending on the amount of storage available and on how you have configured system logging. ESX hosts that are deployed with Auto Deploy store logs on a RAM disk, which means that the amount of space available for logs is small.

If your ESX host is deployed with Auto Deploy, reconfigure your log storage in one of the following ways:

- Redirect logs over the network to a remote host, called syslog collector, such as VCF Operations Log Management (formerly
  VCF Operations for Logs, VMware vRealize Log Insight, and vCenter Log Insight), to collect syslog messages.
- Redirect logs to a NAS or NFS store.

If you redirect logs to non-default storage, such as a NAS or NFS store, you might also want to reconfigure log sizing and rotations for ESX hosts that are installed to disk.

You do not need to reconfigure log storage for ESX hosts that use the default configuration, which stores logs in a scratch directory on the VMFS volume. For these hosts, ESX 9.1 configures logs to best suit your installation, and provides enough space to accommodate log messages.

Table 9: Recommended Minimum Size and Rotation Configuration for hostd, vpxa, and fdm Logs

Log	Maximum Log File Size	Number of Log Files to Preserve	Minimum Disk Space Required
Management Agent (hostd)	10 MB	10	100 MB
VirtualCenter Agent (vpxa)	5 MB	10	50 MB
vSphere HA agent (Fault Domain Manager, fdm)	5 MB	10	50 MB

For information about setting up a remote log server, see Configure Syslog on ESX Hosts.

You can optionally install Log Management, which provides log aggregation and analytics. For more information, see Deploy Log Management.

VMware Host Client System Requirements

Make sure that your browser supports the VMware Host Client.

The following guest operating systems and Web browser versions are supported for the VMware Host Client.

Supported Browsers	Mac OS	Windows 32-bit and 64-bit	Linux
Google Chrome	120+	120+	120+
Mozilla Firefox	115+	115+	115+
Microsoft Edge	120+	120+	N/A

What is VMware vSphere Distributed Services Engine®

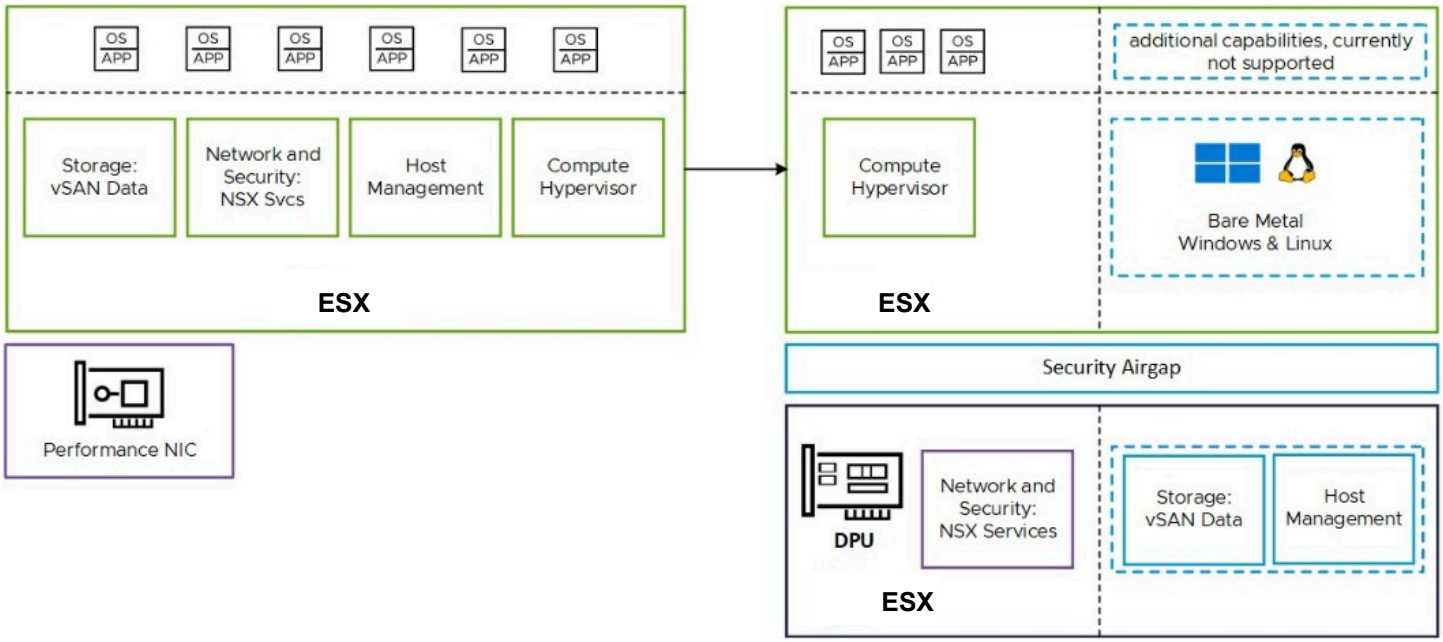
vSphere Distributed Services Engine® is a core vSphere capability that enables customers to use DPUs with vSphere and VMware Cloud Foundation.

ESX 8.0 and later enables breakthrough workload performance to meet ever-increasing throughput and latency needs. With vSphere Distributed Services Engine, infrastructure services are distributed across the different compute resources available on the ESX host, with networking functions offloaded to the DPU. Such a capability works well for modern applications, which are developed using a microservices architecture approach that seeks to break down the application into multiple independent but cooperating services. This increased complexity places new demand for the CPU. For example, processing storage requests or shuttling network traffic for these microservices leaves fewer CPU cycles for the actual workload. In this context, purpose-built accelerators such as DPUs can take on the new compute burden and help you improve the performance and efficiency of infrastructure.

With vSphere Distributed Services Engine, DPUs can accelerate the performance of your network and increase data throughput, while placing no operational burden of managing the lifecycle of DPUs, as the existing Day-0, Day-1, and Day-2 vSphere experience does not change. vSphere Distributed Services Engine is supported by DPUs from NVIDIA and AMD, and server designs from Dell, HPE, Lenovo, and Fujitsu. vSphere Distributed Services Engine is available on servers with pre-installed DPUs.

Starting with ESX 8.0, you can offload functionality that runs on the core CPU onto the DPU to significantly improve the network and security performance. As illustrated in the Evolving vSphere Architecture diagram, DPUs can also handle additional capabilities such as storage offload and bare metal management, but these additional capabilities are currently not supported.

Figure 1: Evolving vSphere Architecture



vSphere Distributed Services Engine offloads and accelerates infrastructure functions on the DPU by introducing a VMware vSphere Distributed Switch on the DPU and VMware NSX Networking and Observability, which allows you to proactively monitor, identify, and mitigate network infrastructure bottlenecks without complex network taps. The DPU becomes a new control point to scale infrastructure functions and enables security controls that are agentless and decoupled from the workload domain.

With vSphere Distributed Services Engine, you can:

- Install and update ESX images simultaneously on the x86 server and the attached supported DPU to reduce operational overhead of DPU lifecycle management with integrated vSphere workflows.
- Set alarms for DPU hardware alerts and monitor performance metrics on core, memory, and network throughput from the familiar vCenter interfaces, without the need of new tools.
- Accelerate vSphere Distributed Switch on the DPU to improve network performance and utilize available CPU cycles to achieve higher workload consolidation per ESX host.
- Get vSphere DRS and vSphere vMotion support for VMs running on ESX hosts with DPUs attached to get the benefits of passthrough without sacrificing on VM portability.
- Improve the security of infrastructure with zero-trust security.

vSphere Distributed Services Engine does not require a separate ESX license. An internal network that is isolated from other networks, connects the DPUs with ESX hosts. ESX 8.0 and later server builds are unified images, which contain both x86 and DPU content. In your environment, you see DPUs as new objects during installation and upgrade, and in networking, storage, and host profile workflows.

High Availability with VMware vSphere Distributed Services Engine

With ESX 8.0 Update 3 and later, you can opt for a VMware vSphere Distributed Services Engine installation with 2 data processing units (DPUs) to achieve high availability.

In vSphere systems with a single DPU, the device might become the single point of failure for workloads offloaded to the DPU, such as networking functions, and impact data and productivity. Starting with ESX 8.0 Update 3, vSphere Distributed Services Engine is also available on servers with 2 pre-installed DPUs, which provides hardware redundancy and resiliency.

You can utilize the two DPUs in Active/Standby mode to provide high availability. Such configuration provides redundancy in the event one of the DPUs fails. In the high availability configuration, both DPUs are assigned to the same NSX-backed vSphere Distributed Switch. For example, DPU-1 is attached to vmnic0 and vmnic1 of the vSphere Distributed Switch and DPU-2 is attached to vmnic2 and vmnic3 of the same vSphere Distributed Switch.

You can also utilize the two DPUs as independent devices to increase offload capacity per ESX host. Each DPU is attached to a separate vSphere Distributed Switch and you have no failover between DPUs in such configuration.

Dual-DPU systems can use NVIDIA or Pensando devices. In ESX 8.0 Update 3 and later, dual-DPU systems are supported by Lenovo server designs. The DPU devices on a dual DPU server must be identical in all aspects: same vendor, same hardware version and same firmware. For a list of current vendors and server designs for VMware vSphere Distributed Services Engine, see the Broadcom Compatibility Guide.

Installation of VMware vSphere Distributed Services Engine with 2 DPUs

vSphere Distributed Services Engine does not require a separate ESX license. ESX 8.0 Update 3 and later server builds are unified images, which contain both x86 and DPU content, and you cannot install x86 and DPU content separately. The installation procedure on both DPUs, either interactive or scripted, also happens in parallel and you see minimal performance loss as compared to a single-DPU system.

Starting with ESX 8.0 Update 3, you can get a pre-installed server configuration with 2 DPUs from Dell or Lenovo, or add a second DPU to a single DPU system on the supported dual DPU servers from Dell or Lenovo.

Note:

In any case, you need to run a complete fresh ESX 8.0 Update 3 or later installation on your system, not only on the newly added DPUs.

Error Handling, Failover, and Rollback for VMware vSphere Distributed Services Engine

Before installing VMware vSphere Distributed Services Engine, see the error handling, failover, and rollback options.

Error Handling

An installation failure of either x86 and DPU content on an ESX host marks the entire installation procedure as failed.

While the expectation is that the software state of DPUs remains identical at all times, in the unlikely case of an error during a lifecycle operation, such as installation or upgrade of a component, the operation might pass on one DPU but fail on the other. Since each lifecycle operation occurs within the boundaries of each DPU, errors do not affect the state of the other DPU, but the overall result of the installation is still marked as a failure.

During interactive install, in vSphere Lifecycle Manager workflows, and when you use ESXCLI, you receive information about the DPU on which the operation failed.

After a successful installation, in case of DPU errors, the recommended action is to restart the affected ESX host. If the DPU is still accessible from the ESX host, the general log bundle collection is sufficient for troubleshooting. If the DPU is

not accessible from the ESX host, logging in to the DPU from a BMC, iLO, or iDRAC interface can provide troubleshooting logs.

Failover

Failover support in ESX 8.0 Update 3 and later is limited to one of the DPUs becoming non-functional due to software errors within the DPU or a physical disconnect of one of the DPUs, such as cable disconnect. Failover due to Peripheral Component Interconnect (PCI) level errors is not supported.

Rollback

Rollback is a best effort mechanism to restore the system to a previous working state in case of a failure before the jumpstart phase of the ESX boot. Rollback on both x86 servers and the attached supported DPUs is automatic in case of an error during booting. You can also opt for a manual rollback by pressing `Shift+R` before the bootloader starts, to return to a previous good state.

Any failure after the jumpstart phase starts does not result in a rollback.

Table 10: Rollback scenarios for VMware vSphere Distributed Services Engine installation

Scenario	Number of reboots required
Both DPUs boot correctly. ESX does not boot correctly.	2
Both DPUs do not boot correctly. ESX boots correctly.	1
One of the DPUs boots with an earlier version than the other DPU and ESX .	2
One of the DPUs boots with an earlier version than the other DPU and ESX does not boot correctly.	2

Customizing Installations with vSphere ESX Image Builder

You can use VMware vSphere®ESX™ Image Builder CLI to create ESX installation images with a customized set of updates, patches, and drivers.

You can use vSphere ESX Image Builder with the vSphere Client or with VCF PowerCLI to create an ESX installation image with a customized set of ESX updates and patches. You can also include third-party network or storage drivers that are released between vSphere releases.

You can deploy an ESX image created with vSphere ESX Image Builder in either of the following ways:

- By burning it to an installation DVD.
- Through vCenter, using the Auto Deploy feature.

In this chapter, you can read about:

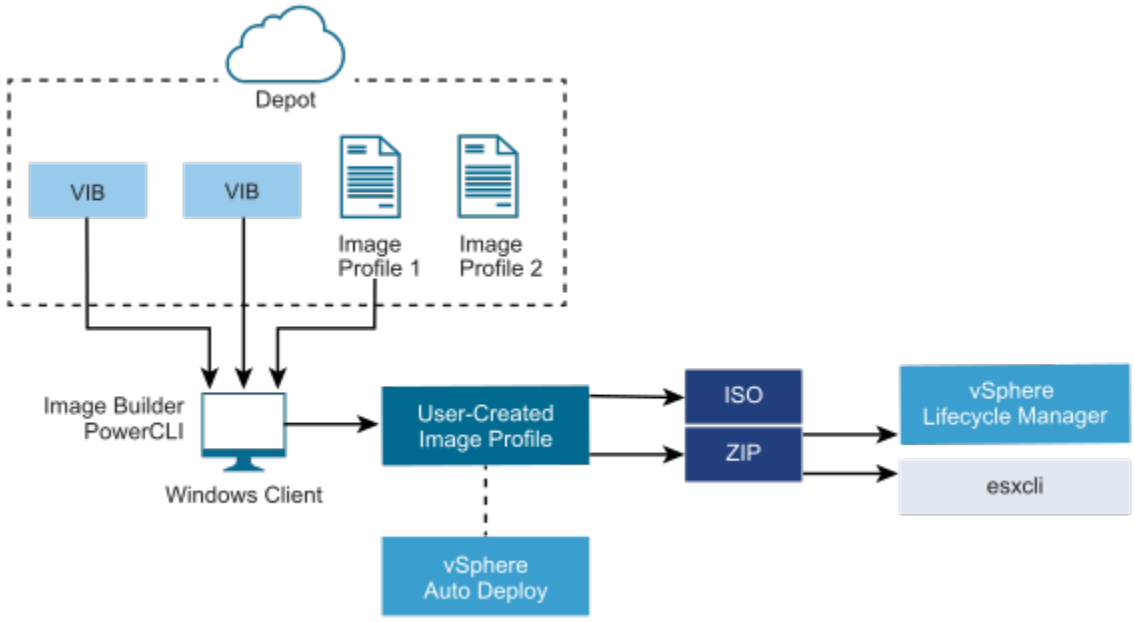
- How the vSphere ESX Image Builder Works
- Structure of ImageProfile, SoftwarePackage, and ImageProfileDiff Objects
- Configure vSphere ESX Image Builder
- Using VMware.Image Builder Cmdlets
- ESX Image Profile Tasks
- vSphere ESX Image Builder Workflows with VCF PowerCLI Cmdlets

How the vSphere ESX Image Builder Works

Create ESX image profiles for use by vSphere Auto Deploy, add custom third-party drivers to image profiles and export them, or perform upgrades.

With vSphere ESX Image Builder you can create ESX image profiles for use by vSphere Auto Deploy, add custom third-party drivers to existing image profiles and export to ISO or bundle, and perform upgrades. For basic concepts related to the way vSphere software is created, packaged, and distributed, see the Software Packaging Units That vSphere Lifecycle Manager Can Consume topic in the *Managing Host and Cluster Lifecycle* guide.

Figure 2: Image Builder Architecture



You use vSphere ESX Image Builder cmdlets for managing the software to deploy to your ESX hosts in several different situations.

Table 11: Cases Where You Can Use vSphere ESX Image Builder

Use Case for vSphere ESX Image Builder	Description
Create image profiles for use by vSphere Auto Deploy	Use vSphere ESX Image Builder to create an image profile that defines the VIBs that vSphere Auto Deploy uses to provision hosts.
Add custom third-party drivers to existing image profile and export to ISO or bundle	When you add a third-party driver or extension custom VIBs to your ESX hosts, use vSphere ESX Image Builder to clone the base image provided by Broadcom, add the custom VIBs, and export to ISO or to offline bundle ZIP file.
Perform upgrades	If you upgrade a system that includes custom extensions or drivers, you can use vSphere ESX Image Builder to create a custom image profile that includes vSphere 8.0 and later compatible VIBs for the custom extensions. Export the custom image profile to an ISO or to a ZIP to upgrade your system by using vSphere Lifecycle Manager baselines.

The vSphere ESX Image Builder cmdlets take image profiles and VIBs as input and produce various outputs.

Table 12: Input and Output to the vSphere ESX Image Builder Cmdlets

Parameter	Description
Input	Image profiles and VIBs that are located in a software depot are used as input to VCF PowerCLI cmdlets running on a Windows client.
Output	VCF PowerCLI cmdlets create custom image profiles that can be exported to an ISO image or an offline depot ZIP file. ISO images are used for installation. The ZIP depot can be used by vSphere Lifecycle Manager or by `esxcli software` commands to update or install images. Image profiles are also used in vSphere Auto Deploy rules to customize the software to provision ESX hosts with.

Image Profiles

Image profiles define the set of VIBs that an ESX installation or update process uses. Image profiles apply to ESX hosts provisioned with vSphere Auto Deploy. You define and manipulate image profiles with vSphere ESX Image Builder.

Image Profile Requirements

You can create a custom image profile from scratch or clone an existing profile and add or remove VIBs. A profile must meet the following requirements to be valid.

- Each image profile must have a unique name and vendor combination.
- Each image profile has an acceptance level. When you add a VIB to an image profile with an vSphere ESX Image Builder cmdlet, Image Builder checks that the VIB matches the acceptance level defined for the profile.
- You cannot remove VIBs that are required by other VIBs.
- You cannot include two versions of the same VIB in an image profile. When you add a new version of a VIB, the new version replaces the existing version of the VIB.

Image Profile Validation

An image profile and its VIBs must meet several criteria to be valid.

- Image profiles must contain at least one base VIB and one bootable kernel module.
- If any VIB in the image profile depends on another VIB, that other VIB must also be included in the image profile. VIB creators store that information in the SoftwarePackage object's Depends property.
- VIBs must not conflict with each other. VIB creators store conflict information in the SoftwarePackage object's Conflicts property.
- Two VIBs with the same name, but two different versions, cannot coexist. When you add a new version of a VIB, the new version replaces the existing version of the VIB.
- No acceptance level validation issues exist.

When you make a change to an image profile, vSphere ESX Image Builder checks that the change does not invalidate the profile.

Dependency Validation	When you add or remove a VIB, vSphere ESX Image Builder checks that package dependencies are met. Each SoftwarePackage object includes a Depends property that specifies a list of other VIBs that VIB depends on. See Structure of ImageProfile, SoftwarePackage, and ImageProfileDiff Objects .
Acceptance Level Validation	vSphere ESX Image Builder performs acceptance level validation each time an image profile is created or changed. vSphere ESX Image Builder checks the acceptance level of VIBs in the image profile against the minimum allowed acceptance level of the profile. The acceptance level of the VIB is also validated each time the signature of a VIB is validated.

VIB Validation During Export

When you export an image profile to an ISO, vSphere ESX Image Builder validates each VIB by performing the following actions.

- Checks that no conflicts exist by checking the Conflicts property of each SoftwarePackage object.
- Performs VIB signature validation. Signature validation prevents unauthorized modification of VIB packages. The signature is a cryptographic checksum that guarantees that a VIB was produced by its author. Signature validation also happens during installation of VIBs on an ESX host and when the vSphere Auto Deploy server uses VIBs.
- Checks that VIBs follow file path usage rules. VMware tests `VMwareCertified` and `VMwareAccepted` VIBs to guarantee those VIBs always follow file path usage rules.

Working with Acceptance Levels

Hosts, image profiles, and individual VIBs have acceptance levels. VIB acceptance levels show how the VIB was tested. Understanding what each acceptance level implies, how to change levels, and what a change implies is an important part of installation and update procedures.

Acceptance levels are set for hosts, image profiles, and individual VIBs. The default acceptance level for an ESX image or image profile is PartnerSupported.

Host acceptance levels The host acceptance level determines which VIBs you can install on a host. You can change a host's acceptance level with ESXCLI commands. By default, ESX hosts have an acceptance level of `PartnerSupported` to allow for easy updates with `PartnerSupported` VIBs.

> **Note:**
>
> VMware supports hosts at the `PartnerSupported` acceptance level. For problems with individual VIBs with `PartnerSupported` acceptance level, contact your partner's support organization.

Image profile acceptance levels The image profile acceptance level is set to the lowest VIB acceptance level in the image profile. If you want to add a VIB with a low acceptance level to an image profile, you can change the image profile acceptance level with the `Set-EsxImageProfile` cmdlet. See Set the Image Profile Acceptance Level.

The vSphere Lifecycle Manager does not display the actual acceptance level. Use vSphere ESX Image Builder cmdlets to retrieve the acceptance level information for VIBs and image profiles.

VIB acceptance levels A VIB's acceptance level is set when the VIB is created. Only the VIB creator can set the acceptance level.

If you attempt to provision a host with an image profile or VIB that has a lower acceptance level than the host, an error occurs. Change the acceptance level of the host to install the image profile or VIB. See Change the Host Acceptance Level. Changing the acceptance level of the host changes the support level for that host.

The acceptance level of a host, image profile, or VIB lets you determine who tested the VIB and who supports the VIB. VMware supports the following acceptance levels .

VMwareCertified The VMwareCertified acceptance level has the most stringent requirements. VIBs with this level go through thorough testing fully equivalent to VMware in-house Quality Assurance testing for the same technology. Today, only I/O Vendor Program (IOVP) program drivers are published at this level. VMware takes support calls for VIBs with this acceptance level.

VMwareAccepted VIBs with this acceptance level go through verification testing, but the tests do not fully test every function of the software. The partner runs the tests and VMware verifies the result. Today, CIM providers and PSA plug-ins are among the VIBs published at this level. VMware directs customers with support calls for VIBs with this acceptance level to contact the partner's support organization.

PartnerSupported VIBs with the PartnerSupported acceptance level are published by a partner that VMware trusts. The partner performs all testing. VMware does not verify the results. This level is used for a new or nonmainstream technology that partners want to enable for VMware systems. Today, driver VIB technologies such as Infiniband, ATAoE, and SSD are at this level with nonstandard hardware drivers. VMware directs customers with support calls for VIBs with this acceptance level to contact the partner's support organization.

CommunitySupported The CommunitySupported acceptance level is for VIBs created by individuals or companies outside of VMware partner programs. VIBs at this level have not gone through any VMware-approved testing program and are not supported by VMware Technical Support or by a VMware partner.

Change the Host Acceptance Level

You can lower the host acceptance level to match the acceptance level for a VIB or image profile you want to install.

Install ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.

The acceptance level of each VIB on a host must be at least as high as the acceptance level of the host. For example, you cannot install a VIB with PartnerSupported acceptance level on a host with `VMwareAccepted` acceptance level. You must first lower the acceptance level of the host. For more information on acceptance levels, see Working with Acceptance Levels.

> **Warning:**
>
> Changing the host acceptance level to `CommunitySupported` affects the supportability of your host and might affect the security of your host.

1. Retrieve the acceptance level for the VIB or image profile.

Option	Description
View information for all VIBs	`esxcli --server=`*`server_name`* `software`

Option	Description
	`sources vib list --depot=depot_URL`
View information for a specified VIB	`esxcli --server=server_name software sources vib list --viburl=vib_URL`
View information for all image profiles	`esxcli --server=server_name software sources profile list --depot=depot_URL`
View information for a specified image profile	`esxcli --server=server_name software sources profile get --depot=depot_URL --profile=profile_name`

2. View the host acceptance level.
   `esxcli --server=server_name software acceptance get`
3. Change the acceptance level of the host.
   ```
   esxcli
       --server=server_name software acceptance set --level=acceptance_level
   ```
   The value for *acceptance_level* can be `VMwareCertified`, `VMwareAccepted`, `PartnerSupported`, or `CommunitySupported`. The values for *acceptance_level* are case-sensitive.

   Note:
   If the host has a higher acceptance level than the VIB or image profile you want to add, you can run commands in the `esxcli software vib` or `esxcli software profile` namespace with the --force option. When you use the --force option, a warning appears because you enforce a VIB or image profile with lower acceptance level than the acceptance level of the host and your setup is no longer consistent. The warning is repeated when you install VIBs, remove VIBs, or perform certain other operations on the host that has inconsistent acceptance levels.

Set the Image Profile Acceptance Level

If you want to add a VIB to an image profile, and the acceptance level of the VIB is lower than that of the image profile, you can clone the image profile with a lower acceptance level or change the image profile's acceptance level.

Install VCF PowerCLI and all prerequisite software. See Configure vSphere ESX Image Builder.

You can specify `VMwareCertified`, `VMwareAccepted`, `PartnerSupported`, or `CommunitySupported` as an acceptance level of an image profile. If you lower the acceptance level, the level of support for the image profile and hosts that you provision with it changes. For more information, see Working with Acceptance Levels.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

   The cmdlet returns one or more `SoftwareDepot` objects.
2. Get the acceptance level for the image profile.
   `Get-EsxImageProfile -Name string`
3. Set the acceptance level of the image profile.
   `Set-EsxImageProfile -Name string -AcceptanceLevel level`

Structure of ImageProfile, SoftwarePackage, and ImageProfileDiff Objects

Knowing the structure of `ImageProfile`, `SoftwarePackage`, and `ImageProfileDiff` objects helps you manage deployment and upgrade processes.

ImageProfile Object Properties

The `ImageProfile` object, which is accessible with the `Get-EsxImageProfile` VCF PowerCLI cmdlet, has the following properties.

Name	Type	Description
`AcceptanceLevel`	`AcceptanceLevel`	Determines which VIBs you can add to the profile. Levels are VMwareCertified, VMwareAccepted, PartnerSupported, and CommunitySupported. See Working with Acceptance Levels.
`Author`	`System.String`	The person who created the profile. 60 characters or fewer
`CreationTime`	`System.DateTime`	The timestamp of creation time
`Description`	`System.String`	The full-text description of profile. No length limit.
`GUID`	`System.String`	Globally unique ID of the image profile.
`ModifiedTime`	`System.DateTime`	The timestamp of last modification time.
`Name`	`System.String`	The name of the image profile. 80 characters or fewer.
`ReadOnly`	`System.Boolean`	When set to `true`, the profile cannot be edited. Use `Set-EsxImageProfile -Readonly` to make your custom image profiles read only.
`Rules`	`ImageProfileRule[]`	Any OEM hardware requirements and restrictions that the image profile might have. If matching hardware is available, vSphere Auto Deploy verifies the value of this property when deploying an image profile and deploys the profile.
`Vendor`	`System.String`	The organization that publishes the profile. 40 characters or fewer.
`VibList`	`SoftwarePackage[]`	The list of VIB IDs the image contains.

SoftwarePackage Object Properties

When preparing an image profile, you can examine software packages to decide which packages are suitable for inclusion. The `SoftwarePackage` object has the following properties.

Name	Type	Description
`AcceptanceLevel`	`AcceptanceLevel`	The acceptance level of this VIB.
`Conflicts`	`SoftwareConstraint[]`	A list of VIBs that cannot be installed at the same time as this VIB. Each constraint uses the following format: `package-name[<<|<=|=|>=|<< version]`
`Depends`	`SoftwareConstraint[]`	A list of VIBs that must be installed at the same time as this VIB. Same constraint format as `Conflicts` property.
`Description`	`System.String`	The long description of the VIB.
`Guid`	`System.String`	The unique ID for the VIB.
`LiveInstallOk`	`System.Boolean`	True if live installations of this VIB are supported.
`LiveRemoveOk`	`System.Boolean`	True if live removals of this VIB are supported.
`MaintenanceMode`	`System.Boolean`	True if hosts must be in maintenance mode for installation of this VIB.

Name	Type	Description
Name	System.String	The name of the VIB. Uniquely describes the package on a running ESX system.
Provides	SoftwareProvides	The list of virtual packages or interfaces this VIB provides. See SoftwareProvide Object Properties.
ReferenceURLs	SupportReference[]	The list of SupportReference objects with in-depth support information. The SupportReference object has two properties, Title and URL, both of type System.String.
Replaces	SoftwareConstraint[]	The list of SoftwareConstraint objects that identify VIBs that replace this VIB or make it obsolete. VIBs automatically replace VIBs with the same name but lower versions.
ReleaseDate	System.DateTime	Date and time of VIB publication or release.
SourceUrls	System.String[]	The list of source URLs from which this VIB can be downloaded.
StatelessReady	System.Boolean	True if the package supports host profiles or other technologies that make it suitable for use with vSphere Auto Deploy.
Summary	System.String	A one-line summary of the VIB.
Tags	System.String[]	An array of string tags for this package, defined by the vendor or publisher. Tags can be used to identify characteristics of a package.
Vendor	System.String	The VIB vendor or publisher.
Version	System.String	The VIB version.
VersionObject	Software.Version	The VersionObject property is of type SoftwareVersion. The SoftwareVersion class implements a static Compare method to compare two versions of strings. See SoftwareVersion Object Properties.

ImageProfileDiff Object Properties

When you run the Compare-EsxImageProfile cmdlet, you pass in two parameters, first the reference profile, and then the comparison profile. The cmdlet returns an ImageProfileDiff object, which has the following properties.

Name	Type	Description
CompAcceptanceLevel	System.String	The acceptance level for the second profile that you passed to Compare-EsxImageProfile.
DowngradeFromRef	System.String[]	The list of VIBs in the second profile that are downgrades from VIBs in the first profile.
Equal	System.Boolean	True if the two image profiles have identical packages and acceptance levels.
OnlyInComp	System.String	The list of VIBs found only in the second profile that you passed to Compare-EsxImageProfile.
OnlyInRef	System.String[]	The list of VIBs found only in the first profile that you passed to Compare-EsxImageProfile.
PackagesEqual	System.Boolean	True if the image profiles have identical sets of VIB packages.

Name	Type	Description
RefAcceptanceLevel	System.String	The acceptance level for the first profile that you passed to Compare-EsxImageProfile.
UpgradeFromRef	System.String[]	The list of VIBs in the second profile that are upgrades from VIBs in the first profile.

SoftwareVersion Object Properties

The SoftwareVersion object lets you compare two version strings. The object includes a Compare static method that accepts two strings as input. If the first version string is a higher number than the second version stringand, it returns 1. Compare returns 0 if two versions strings are equal. Compare returns -1 if the second version string is a higher number than the first string. The object has the following properties.

Name	Type	Description
Version	System.String	The part of the version before the hyphen. This part indicates the primary version.
Release	System.String	The part of the version after the hyphen. This part indicates the release version.

SoftwareConstraint Object Properties

The SoftwareConstraint object implements a MatchesProvide method. The method accepts a SoftwareProvides or SoftwarePackage object as input. If the constraint matches the SoftwareProvide or the SoftwarePackage, it returns True or returns False otherwise.

The SoftwareConstraint object includes the following properties.

Name	Type	Description
Name	System.String	The name of the constraint. This name should match a corresponding SoftwareProvideName property.
Relation	System.String	An enum, or one of the following comparison indicators: <<, <=, = >=, >>. This property can be $null if the constraint does not have a Relation and Version property.
Version	System.String	The version to match the constraint against. This property can be $null if the constraint does not have a Relation and Version property.
VersionObject	SoftwareVersion	The version represented by a SoftwareVersion object.

SoftwareProvide Object Properties

The SoftwareProvide object includes the following properties.

Name	Type	Description
Name	System.String	The name of the provide.
Version	System.String	The version of the provide. Can be $null if the provider does not specify a version.
Release	System.String	The version of the provide as represented by a SoftwareVersion object. See Structure of ImageProfile, SoftwarePackage, and ImageProfileDiff Objects.

Configure vSphere ESX Image Builder

Before you can run vSphere ESX Image Builder cmdlets, you must install VCF PowerCLI and all prerequisite software.

Before you can run vSphere ESX Image Builder cmdlets, you must install VCF PowerCLI and all prerequisite software. The vSphere ESX Image Builder module is included with the VCF PowerCLI installation. If you want to manage vSphere ESX Image Builder with VCF PowerCLI cmdlets, verify that PowerShell 7.5 is installed. See the VCF PowerCLI User's Guide.

1. Open PowerShell on your workstation.
2. To install all VCF PowerCLI modules, run the command: `Install-Module VCF.PowerCLI -Scope CurrentUser`. Alternatively, you can install individual VCF PowerCLI modules by running the `Install-Module` cmdlet with the module name. If you see a warning that you are installing modules from an untrusted repository, press **y** and then press **Enter** to confirm the installation.

   You can verify that the VCF PowerCLI module is available by using the command:

   ```
   Get-Module -Name VMware.PowerCLI* -ListAvailable
   ```

Review Using VMware.Image Builder Cmdlets. If you are new to VCF PowerCLI, read the *VCF PowerCLI User's Guide*.

Use vSphere ESX Image Builder cmdlets and other VCF PowerCLI cmdlets and PowerShell cmdlets to manage image profiles and VIBs. Use `Get-Help cmdlet_name` at any time for command-line help.

Configure the vSphere ESX Image Builder

Before you can use vSphere ESX Image Builder with the vSphere Client, you must verify that the service is enabled and running.

Starting with ESX 9.0, due to the increase in the ESX image size, the default cache size of the vSphere Auto Deploy repository is set to 6 GB. The vSphere Auto Deploy server uses the repository to store data it needs, including the rules and rule sets you create and the VIBs and image profiles that you specify in your rules. Best practice is to allocate enough room for four image profiles and some extra space. Determine how much space to reserve for the vSphere Auto Deploy repository by considering how many image profiles you expect to use.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. Click **Enable Image Builder** to activate the service.

   The **Software Depots** tab appears.

- Add a Software Depot.
- Import a Software Depot.
- Clone an Image Profile.
- Create an Image Profile.
- Prepare Your System for vSphere Auto Deploy.
- You can change the default configuration properties of the **Image Builder Service**. For more information, see "Configuring vCenter" in the *vCenter and Host Management* documentation.

Using VMware.ImageBuilder Cmdlets

With VMware.ImageBuilder cmdlets, you can take advantage of all VCF PowerCLI features.

VMware.Image Builder cmdlets are implemented as Microsoft PowerShell cmdlets and included in VCF PowerCLI. You can take advantage of all VCF PowerCLI features by using VMware.ImageBuilder cmdlets. Experienced PowerShell users can use VMware.ImageBuilder cmdlets just like other PowerShell cmdlets. If you are new to PowerShell and VCF PowerCLI, follow these tips.

You can type cmdlets, parameters, and parameter values in thePowerShell console.

- Get help for any cmdlet by running `Get-Help cmdlet_name`.
- Remember that PowerShell is not case-sensitive.
- Use tab completion for cmdlet names and parameter names.
- Format any variable and cmdlet output by using `Format-List` or `Format-Table` or their short forms `fl` or `ft`. See `Get-Help Format-List`.

- Use wildcards for searching and filtering VIBs and image profiles. All wildcard expressions are supported.

Passing Parameters by Name

You can pass in parameters by name in most cases and surround parameter values that contain spaces or special characters with double quotes.

```
Add-EsxSoftwarePackage -ImageProfile profile42 -SoftwarePackage "partner package 35"
```

Passing Parameters as Objects

If you want to do scripting and automation, you can pass parameters as objects. You can use the technique with cmdlets that return multiple objects or with cmdlets that return a single object.

1. Bind the output of a cmdlet that returns multiple objects to a variable.
   ```
   $profs = Get-EsxImageProfile
   ```
2. When you run the cmdlet that needs the object as input, access the object by position, with the list starting with 0.
   ```
   Add-EsxSoftwarePackage -ImageProfile $profs[4] -SoftwarePackage partner-pkg
   ```

The example adds the specified software package to the fifth image profile in the list returned by `Get-EsxImageProfile`.

Most of the examples in the *vCenter Deployment and Setup* documentation pass in parameters by name. vSphere ESX Image Builder Workflows with VCF PowerCLI Cmdlets includes examples that pass parameters as objects.

VMware.ImageBuilder Cmdlets Overview

The VMware.ImageBuilder component of VCF PowerCLI provides cmdlets for managing VIBs, image profiles, and other content in software depots.

vSphere 7.0 and later introduce new ways of packaging VIBs along with legacy bulletins and patches. Software depots contain base images, vendor addons, and components, along with VIBs and image profiles. VCF.PowerCLI provide cmdlets that work with the new content in software depots.

VMware.ImageBuilder includes the following cmdlets.

> **Note:**
> When you run VMware.ImageBuilder cmdlets, provide all parameters on the command line when you invoke the cmdlet. Supplying parameters in interactive mode is not recommended.

Run `Get-Help` *`cmdlet_name`* at the VCF PowerCLI prompt for detailed reference information.

Table 13: VMware.ImageBuilder Cmdlets Used with Legacy Content in Software Depots

Cmdlet	Description
`Add-EsxSoftwareDepot`	Adds the software depot or ZIP file at the specified location to your current environment. Downloads metadata from the depot and analyzes VIBs for dependencies.
`Remove-EsxSoftwareDepot`	Disconnects from the specified software depot.
`Get-EsxSoftwareDepot`	Returns a list of software depots that are in the current environment. If you want to examine and manage image profiles and VIBs, you must first add the corresponding software depot to your environment.
`Get-EsxSoftwarePackage`	Returns a list of software package objects (VIBs). Use this cmdlet's options to filter the results.
`Get-EsxImageProfile`	Returns an array of `ImageProfile` objects from all currently added depots.
`New-EsxImageProfile`	Creates a new image profile. In most cases, creating a new profile by cloning an existing profile is recommended. See Clone an Image Profile with VCF PowerCLI Cmdlets.
`Set-EsxImageProfile`	Modifies a local `ImageProfile` object and performs validation tests on the modified profile. The cmdlet returns the modified object but does not persist it.
`Export-EsxImageProfile`	Exports an image profile as either an ESX ISO image for ESX installation, or as a ZIP file.

Cmdlet	Description
`Compare-EsxImageProfile`	Returns an `ImageProfileDiff` structure that shows whether the two profiles have the same VIB list and acceptance level. See Working with Acceptance Levels.
`Remove-EsxImageProfile`	Removes the image profile from the software depot.
`Add-EsxSoftwarePackage`	Adds one or more new packages (VIBs) to an existing image profile.
`Remove-EsxSoftwarePackage`	Removes one or more packages (VIBs) from an image profile.
`Set-ESXImageProfileAssociation`	Associates the specified image profile with the specified ESX system.

Table 14: VMware.ImageBuilder Cmdlets Used with New Content in Software Depots

Cmdlet	Description
`Get-DepotAddons`	Retrieves an array of objects that provide basic information about addons in a software depot.
`Get-DepotBaseImages`	Retrieves an array of objects that provide basic information about base images in a software depot.
`Get-DepotComponents`	Retrieves an array of objects that provide basic information about components in a software depot.
`Get-DepotInfo`	Retrieves basic information about the software depot located at the specified file path or URL address.
`Get-DepotVibs`	Retrieves an array of objects that provide basic information about VIBs in a software depot.
`New-IsoImage`	Generates an ISO image by using the specified software depot and software specification at the specified file path.
`New-PxeImage`	Generates a PXE image by using the specified software depot and software specification at the specified file path.
`New-OfflineBundle`	Generates a collection of metadata and VIBs in an offline bundle that you can use for ESX updates.

ESX Image Profile Tasks

Manipulate software depots, image profiles, and VIBs by using either the VMware.Image Builder component of VCF PowerCLI or the vSphere Client.

- Add a Software Depot
- Import a Software Depot
- Clone an Image Profile
- Create an Image Profile
- Edit an Image Profile
- Compare Image Profiles
- Move an Image Profile to a Different Software Depot
- Export an Image Profile to ISO or Offline Bundle ZIP
- Regenerate an Image Profile
- Preserve Image Profiles Across Sessions with VCF PowerCLI
- Compare VIBs with VCF PowerCLI Cmdlets

Add a Software Depot

Add one or more software depots to the vSphere ESX Image Builder inventory to customize image profiles.

Before you can work with software depots and customize image profiles, you must add one or more software depots to the vSphere ESX Image Builder inventory. You can add a software depot by using the vSphere Client.

Verify that the vSphere ESX Image Builder service is enabled and running. See Configure the vSphere ESX Image Builder.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere ESX Image Builder service.

2. On the **Software Depots** tab, click **New**.

   The **Add Software Depot** window appears.

   Note:

   The URLs of the official VMware online depot are now unique for each customer. To update the download sources URLs, see the following Broadcom knowledge base articles 390121 and 390123.

3. Select the type of depot that you want to create.

Option	Action
Online Depot	1. Enter a name of the depot in the inventory. 2. Enter the URL of the online depot.
Custom Depot	Enter the name of the depot in the inventory.

   The VMware online software depot is located at a url such as https://dl.broadcom.com/<Your Download Token>/PROD/COMP/ESX_HOST/main/vmw-depot-index.xml.

4. Click **Add**.
5. Optional: Click the **Software Packages** tab to view the contents of the selected depot and additional information about the packages.
6. Optional: If you added an **Online depot**, you can also:
   - **Check for Updates** to get the latest depot packages.
   - Click **More info** to get additional depot details.

The software depot is added to the list.

- You can associate an image profile with a new vSphere Auto Deploy rule to provision ESX hosts. See Create a Deploy Rule or Clone a Deploy Rule.
- You can associate an image profile with an ESX host. See Add a Host to the vSphere Auto Deploy Inventory.
- Edit the Image Profile Association of a Host.
- **Remove** a custom software depot.

Import a Software Depot

If an offline depot is located on your local file system, import the ZIP file to the vSphere ESX Image Builder inventory.

If an offline depot is located on your local file system, you can import the ZIP file to the vSphere ESX Image Builder inventory by using the vSphere Client.

Verify that the vSphere ESX Image Builder service is enabled and running. see *Configure vSphere ESX Image Builder*.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere ESX Image Builder service.

2. On the **Software Depots** tab, click **Import** .
3. Enter the name of the software depot in the inventory.
4. Click **Browse** and select a ZIP file from the local system, that contains the software depot you want to import.
5. Click **Upload**.

- You can associate an image profile with a new vSphere Auto Deploy rule to provision ESX hosts. See *Create a Deploy Rule* or *Clone a Deploy Rule*.
- You can associate an image profile with an ESX host. See *Add a Host to the vSphere Auto Deploy Inventory*.
- *Edit the Image Profile Association of a Host*.

Clone an Image Profile

Use the vSphere Client to clone image profiles.

You can use the vSphere Client to clone image profiles. You can clone an image profile when you want to make small changes to the VIB list in a profile. Another use case is when you want to use hosts from different vendors and plan to use the same basic profile, but also add vendor-specific VIBs.

- Verify that the vSphere ESX Image Builder service is enabled and running. See *Configure the vSphere Image Builder*.
- Add or import a software depot to the vSphere ESX Image Builder inventory. See *Add a Software Depot* or *Import a Software Depot*.
- Verify that there is at least one custom depot in the vSphere ESX Image Builder inventory.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere ESX Image Builder service.
2. On the **Software Depots** tab, use the drop-down menu to select the software depot that contains the image profile that you want to work with.
3. From the list of image profiles in the depot, select the image profile that you want to clone and click **Clone**.
4. Enter an image profile name, vendor, and description.

   You must enter a unique image profile name.
5. From the **Software depot** drop-down menu, select in which custom depot to add the new image profile.
6. Click **Next**. The Select software packages page appears.
7. From the drop-down menu, select an acceptance level for the image profile.

   The acceptance level of the VIBs you add to the base image must be at least as high as the level of the base image. If you add a VIB with a lower acceptance level to the image profile, you must lower the image profile acceptance level. For more information, see *Working with Acceptance Levels*.
8. Select the VIBs that you want to add to the image profile and deselect the ones that you want to remove, and click **Next**.

   Note:
   The image profile must contain a bootable ESX image to be valid.

   vSphere ESX Image Builder verifies that the change does not invalidate the profile. Some VIBs depend on other VIBs and become invalid if you include them in an image profile separately. When you add or remove a VIB, vSphere ESX Image Builder checks whether the package dependencies are met.
9. On the **Ready to complete** page, review the summary information for the new image profile and click **Finish**.

- You can associate an image profile with a new vSphere Auto Deploy rule to provision ESX hosts. See *Create a Deploy Rule* or *Clone a Deploy Rule*.
- You can associate an image profile with an ESX host. See *Add a Host to the vSphere Auto Deploy Inventory*.
- *Edit the Image Profile Association of a Host*.

Clone an Image Profile with VCF PowerCLI Cmdlets

Cloning a published profile is the easiest way to create a custom image profile. Cloning a profile is especially useful if you want to remove a few VIBs from a profile. You might also want to use hosts from different vendors and reuse the same basic profile, but add vendor-specific VIBs. VMware partners or large installations might consider creating a profile.

- Install the VCF PowerCLI and all prerequisite software. See Configure vSphere ESX Image Builder.
- Verify that you have access to the software depot that contains the image profile you want to clone.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.

Option	Action
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

The cmdlet returns one or more `SoftwareDepot` objects.

2. Optional: Run the `Get-EsxImageProfile` cmdlet to find the name of the profile that you want to clone.

   You can use filtering options with `Get-EsxImageProfile`.

3. Run the `New-EsxImageProfile` cmdlet to create the new profile and use the `-CloneProfile` parameter to specify the profile you want to clone.

   ```
   New-EsxImageProfile -CloneProfile My_Profile -Name "Test Profile 42" -Vendor <vendor-name>
   ```

   This example clones the profile named *My_Profile* and assigns it the name Test Profile 42. You must specify a unique combination of name and vendor for the cloned profile.

See Examine Depot Contents for some examples of filtering.

Customize the image profile by adding or removing VIBs. See Add VIBs to an Image Profile with VCF PowerCLI Cmdlets.

Create an Image Profile

You can create a new image profile by using the vSphere Client instead of cloning an existing one.

You might consider creating a new image profile if it differs significantly from the image profiles in your inventory.

- Verify that the vSphere ESX Image Builder service is enabled and running. See *Configure the vSphere Image Builder*.
- Add or import a software depot to the vSphere ESX Image Builder inventory. See *Add a Software Depot* or *Import a Software Depot*.
- Verify that there is at least one custom depot in the vSphere ESX Image Builder inventory.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere ESX Image Builder service.

2. From the **Software depot** drop-down menu, select in which custom depot to add the new image profile.
3. On the Image Profiles tab, click **New Image Profile**.
4. Enter an image profile name, vendor, and description.

   You must enter a unique image profile name.

5. Click **Next**. The Select software packages page appears.
6. From the drop-down menu, select an acceptance level for the image profile.

   The acceptance level of the VIBs you add to the base image must be at least as high as the level of the base image. If you add a VIB with a lower acceptance level to the image profile, you must lower the image profile acceptance level. For more information, see *Working with Acceptance Levels*.

7. Select the VIBs that you want to add to the image profile and deselect the ones that you want to remove, and click **Next**.

   Note:
   The image profile must contain a bootable ESX image to be valid.

   vSphere ESX Image Builder verifies that the change does not invalidate the profile. Some VIBs depend on other VIBs and become invalid if you include them in an image profile separately. When you add or remove a VIB, vSphere ESX Image Builder checks whether the package dependencies are met.

8. On the **Ready to complete** page, review the summary information for the new image profile and click **Finish**.

- You can associate an image profile with a new vSphere Auto Deploy rule to provision ESX hosts. See *Create a Deploy Rule* or *Clone a Deploy Rule*.

- You can associate an image profile with an ESX host. See *Add a Host to the vSphere Auto Deploy Inventory*.
- *Edit the Image Profile Association of a Host*.
- Select and **Delete** an Image profile.
- **View Software Packages** for the selected image profile.

Create a Custom ESX ISO Image with VCF PowerCLI Cmdlets

With ESX Image Builder, you can customize an ESX image profile, but not combine content from different depots to generate an ISO image. With VCF PowerCLI, you can customize ISO images by using content from multiple software depots and a custom software specification.

- Verify that your VCF PowerCLI version is 9.1 or later.
- Verify that you downloaded the following ZIP files.
  - ESX patch for the ESX version specified in the VMware Cloud Foundation Release Notes or in the list of supported async patches in Broadcom knowledge base article 88287. You can download patches from the Broadcom Support Portal.
  - OEM add-on for ESX from the Broadcom Support Portal. If the ESX version specified in the BOM is not available, contact your vendor to determine which OEM add-on version to use.

1. Gather the required information for the software spec that is used to create the custom ISO.
   a) In VCF PowerCLI, use the Get-DepotBaseImages cmdlet to get the base image version from the zip file for the ESX patch that you downloaded from the patches portal. For example: `Get-DepotBaseImages "c:\temp\VMware-ESX-9.1.x-xxxxxxx-depot.zip"`
   b) Use the Get-DepotAddons cmdlet to get the add-on name and version from the zip file for the OEM add-on for ESX that you downloaded from the Broadcom Support Portal. (if applicable). For example: `Get-DepotAddons "c:\temp\HPE-9.1.x.x.x-xxx-Synergy-Addon-depot.zip"`
2. Create the software spec using the information you gathered in step 1.The software spec is a JSON file that contains information about the ESX version and vendor add-on (if applicable). For example:

```
{
"add_on": {
   "name": "HPE-Custom-Syn-AddOn",
   "version": "9.1.x.x.x.x-xx"
},
"base_image": {
   "version": "9.1.x-x.xx.xxxxxxxx"
},
"components": null,
"hardware_support": null,
"solutions": null
}
```

3. In VCF PowerCLI, use the New-IsoImage cmdlet to generate a custom ISO. For example: `New-IsoImage -SoftwareSpec "c:\temp\HPE-70U1d-custom.JSON" -Depots "c:\temp\VMware-ESX-9.0-17551050-depot.zip" , "c:\temp\HPE-9.1.x.xx.x.x.xx-xxxxxxx-Synergy-Addon-depot.zip" -Destination "c:\temp\HPE-9.1-custom.iso"`

Provide the path to the software spec you created in step 2. The depot(s) include the path to the zip files for the supported ESX version and vendor add-on.The destination includes the path and file name for the custom ISO file.For more information about the New-IsoImage cmdlet, see New-IsoImage.

Create a Custom PXE Image with VCF PowerCLI Cmdlets

Starting with VCF PowerCLI, you can create a custom PXE image by using any software depot and a custom software specification.

- Install VCF PowerCLI.
- Verify that you have access to the software depot that contains the software specification you want to use.

1. Gather the required information for the software specification that you use to create a custom PXE image.
   1. Get the base image version for the required patch or upgrade by running the `Get-DepotBaseImages` cmdlet:
      ```
      PS C:\> Get-DepotBaseImages -Depot C:\VMware-ESX-9.xxxx-xxxxx-depot.zip
      ```
      The command output is:
      ```
      Version                                 Vendor                                  Release date
      -------                                 ------                                  ------------
      9.x.x.xxx.xxxxx                      VMware, Inc.                            04/29/20xx 00:00:00
      ```
   2. Get other packages, such as OEM addons, with cmdlets used with new metadata in software depots. For example:
      ```
      PS C:\> Get-DepotAddons -Depot C:\addon-depot.zip
      ```

   The command output is:
   ```
   Name                    Version                 ID                      Vendor                  Release
    date
   ----                    -------                 --                      ------
    ------------
   testaddonv1             1.0.0-1                 testaddonv1:1.0.0-1     ESXLifecycle QE         02/20/20xx
    18:28:23
   ```

   You can also list all components in a sofware depot with the `Get-DepotComponents` cmdlet:
   ```
   PS C:\> Get-DepotComponents -Depot C:\Intel-i40en_1.12.3.0-1OEM.700.1.0.15843807_18058526.zip
   ```

   The command output is:
   ```
   Name                            Version                         ID
            Vendor
   ----                            -------                         --
           ------
   Intel-i40en                     1.12.3.0-1OEM.xxxxx    Intel-i40en:1.12.3.0-1OEM.xxxxx     Intel
   ```

   You can use any number and combination of online and offline software depots.

2. Create a software specification. For example:
   ```
   {
       "base_image": {
           "version": "9.1.xxxxx"
       },
       "add_on": {
           "name": "testaddonv1",
           "version": "1.0.0-1"
       },
       "components": {
          "Intel-i40en": "1.12.3.0-1OEM.xxxxx"
      }
   }
   ```

   The software specification is a JSON file that contains information about the ESX base image and additional packages, such as a vendor add-on.

3. Generate a custom PXE image by running the `New-PxeImage` cmdlet with the parameters `Depots`,`SoftwareSpec` and `Destination`. For example:
   ```
   New-PxeImage -Depots “c:\temp\VMware-ESX-9.1xxxxx-xxxxx-depot.zip” , “c:\temp\HPE-9.1xxxxx-xxx-Synergy-
   Addon-depot.zip” -SoftwareSpec “c:\temp\HPE-xxx-custom.JSON” -Destination “C:\pxe-image”
   ```

   The depot(s) include the path to the zip files for the supported ESX version and vendor add-on. The destination include the path and file name for the custom PXE file.

   You can pass additional kernel options, create a live image, overwrite existing files, or check acceptance levels for individual VIBs used during the creation of the image. For more information about the `New-PxeImage` cmdlet, see https://developer.broadcom.com/powercli/latest/vmware.imagebuilder/commands/new-pxeimage.

You can use the PXE image in remediation workflows of PXE booted ESX hosts.

Edit an Image Profile

You can edit image profiles by using the vSphere Client. You can change the name, details, and VIB list of an image profile.

- Verify that the vSphere ESX Image Builder service is enabled and running. See *Configure the vSphere Image Builder*.
- Add or import a software depot to the vSphere ESX Image Builder inventory. See *Add a Software Depot* or *Import a Software Depot*.
- Verify that there is at least one custom depot in the vSphere ESX Image Builder inventory.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere ESX Image Builder service.

2. On the **Software Depots** tab, use the drop-down menu to select the software depot that contains the image profile that you want to work with.
3. On the **Image Profiles** tab, select the image profile that you want to edit and click **Edit**.

   The **Edit Image Profile** wizard appears.
4. Optional: Change the vendor and description information of the image profile.
5. Click **Next**.

   The **Select software packages** page appears. DHCP server that you can configure for PXE boot
6. From the drop-down menu, select an acceptance level for the image profile.

   The acceptance level of the VIBs you add to the base image must be at least as high as the level of the base image. If you add a VIB with a lower acceptance level to the image profile, you must lower the image profile acceptance level. For more information, see *Working with Acceptance Levels*.
7. Select the VIBs that you want to add to the image profile and deselect the ones that you want to remove, and click **Next**.

   Note:
   The image profile must contain a bootable ESX image to be valid.

   vSphere ESX Image Builder verifies that the change does not invalidate the profile. Some VIBs depend on other VIBs and become invalid if you include them in an image profile separately. When you add or remove a VIB, vSphere ESX Image Builder checks whether the package dependencies are met.
8. On the **Ready to complete** page, review the summary information for the edited image profile and click **Finish**.

- You can associate an image profile with a new vSphere Auto Deploy rule to provision ESX hosts. See *Create a Deploy Rule* or *Clone a Deploy Rule*.
- You can associate an image profile with an ESX host. See *Add a Host to the vSphere Auto Deploy Inventory*.
- *Edit the Image Profile Association of a Host*.

Add VIBs to an Image Profile with VCF PowerCLI Cmdlets

If an image profile is not set to read only, you can add one or more VIBs to that image profile. If the new VIB depends on other VIBs or conflicts with other VIBs in the profile, a message is displayed at the PowerShell prompt and the VIB is not added.

Install the VCF PowerCLI and all prerequisite software. See Configure vSphere ESX Image Builder.

You can add VIBs from VMware or from VMware partners to an image profile. If you add VMware VIBs, vSphere ESX Image Builder performs validation. If you add VIBs from two or more OEM partners simultaneously, no errors are reported but the resulting image profile might not work. Install VIBs from only one OEM vendor at a time.

If an error about acceptance level problems appears, change the acceptance level of the image profile and the acceptance level of the host. Consider carefully whether changing the host acceptance level is appropriate. VIB acceptance levels are set during VIB creation and cannot be changed.

You can add VIBs even if the resulting image profile is invalid.

Note:
VMware can support only environments and configurations that are proven to be stable and fully functional through rigorous and extensive testing. Use only those supported configurations. You can use custom VIBs if you lower your host acceptance level, and as a result, supportability. In that case, track the changes you made, so you can revert them if you want to remove custom VIBs and restore the host acceptance level to the default (PartnerSupported) later. See Working with Acceptance Levels.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

   The cmdlet returns one or more `SoftwareDepot` objects.

2. Run the `Get-EsxImageProfile` cmdlet to list all image profiles in all currently visible depots.

   The cmdlet returns all available profiles. You can narrow your search by using the optional arguments to filter the output.

3. Clone the profile.

```
New-EsxImageProfile -CloneProfile My_Profile -Name "Test Profile 42" -Vendor "My Vendor"
```

   Image profiles published by VMware and its partners are read only. To make changes, you must clone the image profile. The `vendor` parameter is required.

4. Run the `Add-EsxSoftwarePackage` cmdlet to add a new package to one of the image profiles.

```
Add-EsxSoftwarePackage -ImageProfile My_Profile -SoftwarePackage partner-package
```

   The cmdlet runs the standard validation tests on the image profile. If validation succeeds, the cmdlet returns a modified, validated image profile. If the VIB that you want to add depends on a different VIB, the cmdlet displays that information and includes the VIB that can resolve the dependency. If the acceptance level of the VIB that you want to add is lower than the image profile acceptance level, an error occurs.

Compare Image Profiles

You can compare two image profiles by using the vSphere Client to check if they have the same VIB list, version, or acceptance level.

- Verify that the vSphere ESX Image Builder service is enabled and running. See *Configure the vSphere Image Builder*.
- Add or import a software depot to the vSphere ESX Image Builder inventory. See *Add a Software Depot* or *Import a Software Depot*.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere ESX Image Builder service.

2. On the **Software Depots** tab, use the drop-down menu to select the software depot that contains the image profile that you want to work with.

3. On the **Image Profiles** tab, select an image profile and click **Compare To**.

   The **Compare Image Profile** wizard appears.

4. Click **Change** to select a second image profile.

   The **Select Image Profile** page appears.

5. Select a software depot from the drop-down menu and click on the second image profile.
6. In the **Compare Image Profile** page, select a comparison option from the **Software packages** drop-down menu.
   The left side of the list displays details of the VIBs that the first chosen image profile contains. The right part of the list provides information about the second image profile. The VIBs marked as `Same` are identical in both profiles. VIBs that are present in one of the image profiles are marked as `Missing` next to the image profile that they are not present in.

Compare Image Profiles with VCF PowerCLI Cmdlets

You can compare two image profiles by using the `Compare-EsxImageProfile` cmdlet, for example, to see if they have the same VIB list or acceptance level. Comparing image profiles or their properties is also possible by using the PowerShell comparison operators.

Install the VCF PowerCLI and all prerequisite software. See *Configure vSphere ESX Image Builder*.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

   The cmdlet returns one or more `SoftwareDepot` objects.
2. Optional: Run the `Get-EsxImageProfile` cmdlet to view a list of all image profiles in all available depots.
   In the list, you can locate the names of the image profiles you want to compare.
3. Before comparing the image profiles, assign them to variables.
   For example, you can create variables `$imageProfile1` and `$imageProfile2` to hold the names of the compared images profiles.

```
$imageProfile1
    = Get-EsxImageProfile -Name "ImageProfile1"
$imageProfile2
    = Get-EsxImageProfile -Name "ImageProfile2"
```

4. Compare the two image profiles by using the `Compare-EsxImageProfile` cmdlet or the `-eq` comparison operator, which returns a Boolean value.
   - Compare the two image profiles to get a full description of the differences by using the `Compare-EsxImageProfile` cmdlet.

```
Compare-EsxImageProfile -ReferenceProfile
      $imageProfile1 -ComparisonProfile $imageProfile2
```

   - Compare the two image profiles by VIB list and acceptance level using the `-eq` comparison operator.

```
if ($imageProfile1 -eq $imageProfile2) {
   Write-host "Successfully verified that both image profiles are equal."
} else {
   Write-host "Failed to verify that the image profiles are equal."
}
```

   - Compare the two image profiles by a specific property using the `-eq` comparison operator.

```
if ($imageProfile1.vendor -eq $imageProfile2.vendor) {
   Write-host "Successfully verified that both image profiles are equal."
} else {
   Write-host "Failed to verify that the image profiles are equal."
}
```

Move an Image Profile to a Different Software Depot

You can move image profiles between custom depots by using the vSphere Client and modify it without affecting the source depot's configuration.

- Verify that the vSphere ESX Image Builder service is enabled and running. See *Configure the vSphere Image Builder*.
- Add or import a software depot to the vSphere ESX Image Builder inventory. See *Add a Software Depot* or *Import a Software Depot*.
- Verify that there is at least one custom depot in the vSphere ESX Image Builder inventory.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere ESX Image Builder service.
2. On the **Software Depots** tab, use the drop-down menu to select the software depot that contains the image profile that you want to work with.
3. On the **Image Profiles** tab, select an image profile and click **Move to**.
4. From the drop-down menu, select the custom depot in which you want to move the image profile.
5. Click **OK**.

The image profile is in the new software depot.

Export an Image Profile to ISO or Offline Bundle ZIP

You can export an image profile to an ISO image or a ZIP file by using the vSphere Client.

You can export an image profile to an ISO image or a ZIP file by using the vSphere Client. You can use the ISO image as an ESX installer or to upgrade hosts with vSphere Lifecycle Manager. The ZIP file contains metadata and the VIBs of the image profile. You can use it for ESX upgrades or as an offline depot.

- Verify that the vSphere ESX Image Builder service is enabled and running. See *Configure the vSphere Image Builder*.
- Add or import a software depot to the vSphere ESX Image Builder inventory. See *Add a Software Depot* or *Import a Software Depot*.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere ESX Image Builder service.
2. On the **Software Depots** tab, use the drop-down menu to select the software depot that contains the image profile that you want to work with.
3. On the **Image Profiles** tab, select the image profile that you want to export and click **Export**.

   The **Export Image Profile** window appears.
4. Select the type of the exported file.

Option	Description
ISO	Exports the image profile to a bootable ISO image. If you want to create an ISO image that you can burn to a CD or DVD and use to start a stateless ESX instance, select the **Do not include an installer on the ISO** check box.
ZIP	Exports the image profile to a ZIP file.

5. Optional: If you want to bypass the acceptance level verification of the image profile, select **Skip acceptance level checking**.
6. Click **Ok**.

   The **Download** link starts generating in the "Download Image Profiles" column of the selected image profile.
7. When the image generates successfully, click **Download** to save the exported file.

- You can associate an image profile with a new vSphere Auto Deploy rule to provision ESX hosts. See *Create a Deploy Rule* or *Clone a Deploy Rule*.

- You can associate an image profile with an ESX host. See *Add a Host to the vSphere Auto Deploy Inventory*.
- *Edit the Image Profile Association of a Host*.

Export an Image Profile to an ISO or Offline Bundle ZIP with VCF PowerCLI Cmdlets

You can export an image profile to an ISO image or a ZIP file of component files and folders. You cannot create both by running the cmdlet once. You can use the ISO image as an ESX installer or upload the ISO into vSphere Lifecycle Manager for upgrades.

Install the VCF PowerCLI and all prerequisite software. See Configure vSphere ESX Image Builder.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

   The cmdlet returns one or more `SoftwareDepot` objects.

2. Run `Export-EsxImageProfile` to export the image profile.

Export Format	Cmdlet
ISO images	`Export-EsxImageProfile` with the `-ExportToIso` parameter
Offline depot ZIP files	`Export-EsxImageProfile` with the `-ExportToBundle` parameter

For the ISO image, vSphere ESX Image Builder validates VIB signatures, adds VIB binaries to the image, and downloads the image to the specified location. For the ZIP file, vSphere ESX Image Builder validates VIB signatures and downloads the VIB binaries to the specified location.

Exporting an Image Profile

Follow these steps to export an image profile to an ISO image.

1. Add the software depot.
   ```
   Add-EsxSoftwareDepot -DepotUrl url_or_file
   ```
2. View all available image profiles to find the name of the image profile to export.
   ```
   Get-EsxImageProfile
   ```
3. Export the image profile.
   ```
   Export-EsxImageProfile -ImageProfile "myprofile" -ExportToIso -FilePath iso_name
   ```

Follow these steps to export an image profile to a ZIP file of component files and folders.

1. Add the software depot.
   ```
   Add-EsxSoftwareDepot -DepotUrl url_or_file
   ```
2. View all available image profiles to find the name of the image profile to export.
   ```
   Get-EsxImageProfile
   ```
3. Export the image profile.
   ```
   Export-EsxImageProfile -ImageProfile "myprofile" -ExportToBundle -FilePath C:\my_bundle.zip
   ```

Use the ISO image in an ESX installation or upload the ISO image into vSphere Lifecycle Manager to perform upgrades.

Use the ZIP file to upgrade an ESX installation.

- Import the ZIP file into vSphere Lifecycle Manager for use with patch baselines.
- Download the ZIP file to an ESX host or a datastore and run `esxcli software vib` commands to import the VIBs in the ZIP file.

See the *vSphere Upgrade* documentation.

Regenerate an Image Profile

If you use Auto Deploy to add stateful ESX hosts to a cluster that you manage by using an image, all hosts must have the same software specification.

When an Auto Deploy rule is created and the target cluster is managed by an image, a Preboot Execution Environment (PXE) image is created based on the image specification of the cluster. The generated PXE image is cached and is not automatically updated. As a result, if you modify the image specification in the vSphere Lifecycle Manager, you must update the PXE image manually.

For information how to create a rule to add hosts to a cluster managed by an image, see *Use Auto Deploy to Add a Host to a Cluster Managed by an Image* from the *vSphere Lifecycle Manager* documentation.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deploy Rules** tab, select the desired rule.
   You must select a rule, which matches ESX hosts to a cluster that you manage by an image.
3. If the rule is active, first you must deactivate the rule.
   a) Click the **Activate/Deactive Rules** tab
   b) In the dialog box, select the rule.
   c) In the dialog box, select **Deactivate** and click **OK**.
4. Select **Reacreate Image Profile** and in the confirmation dialog box, click **Recreate**.
5. Optional: Activate the rule again.
   a) Click the **Activate/Deactive Rules** tab
   b) In the dialog box, select the rule.
   c) In the dialog box, select **Activate** and click **OK**.

The PXE image is running the latest image specification.

Preserve Image Profiles Across Sessions with VCF PowerCLI

You can export the image profile to a ZIP file software depot and add that depot in the next session.

When you create an image profile and exit the VCF PowerCLI session, the image profile is no longer available when you start a new session. You can export the image profile to a ZIP file software depot, and add that depot in the next session.

Install the VCF PowerCLI and all prerequisite software. See Configure vSphere ESX Image Builder.

1. In a VCF PowerCLI session, create an image profile, for example by cloning an existing image profile and adding a VIB.
2. Export the image profile to a ZIP file by calling `Export-EsxImageProfile` with the `ExportToBundle` parameter.
   ```
   Export-EsxImageProfile -ImageProfile "my_profile" -ExportToBundle -FilePath
       "C:\isos\temp-base-plus-vib25.zip"
   ```
3. Exit the VCF PowerCLI session.
4. When you start a new VCF PowerCLI session, add the depot that contains your image profile to access it.
   ```
   Add-EsxSoftwareDepot "C:\isos\temp-base-plus-vib25.zip"
   ```

Compare VIBs with VCF PowerCLI Cmdlets

You can compare two VIBs or their properties by using the PowerShell comparison operators.

Install the VCF PowerCLI and all prerequisite software. See Configure vSphere ESX Image Builder.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

   The cmdlet returns one or more `SoftwareDepot` objects.

2. Optional: Run the `Get-EsxSoftwarePackage` cmdlet to view all available VIBs.
   In the list, you can locate the names of the VIBs you want to compare.
3. Before comparing the VIBs, assign them to variables.
   For example, you can create variables `$vib1` and `$vib2` to hold the names of the compared VIBs.

```
$vib1 = Get-EsxSoftwarePackage -Name "ReferenceVIB"
$vib2 = Get-EsxSoftwarePackage -Name "ComparisonVIB"
```

4. Use a comparison operator to compare the VIBs by contents and acceptance level or by a specific property.
   - Compare the two VIBs by their contents and acceptance level.

```
if ($vib1 -eq $vib2) {
   Write-host "Successfully verified that both VIBs are equal."
} else {
   Write-host "Failed to verify that the VIBs are equal."
}
```

   - Compare a specific property of the VIBs by using a comparison operator such as `-eq`, `-lt`, `-le`, `-gt`, or `-ge`.

```
if ($vib1.VersionObject -lt $vib2.VersionObject) {
   Write-host "Successfully verified that both the VIBs are equal."
} else {
   Write-host "Failed to verify that the VIBs are equal."
}
```

vSphere ESX Image Builder Workflows with VCF PowerCLI Cmdlets

vSphere ESX Image Builder workflows are examples for cmdlet use and do not represent actual tasks.

vSphere ESX Image Builder workflows are examples for cmdlet use. Workflows do not represent actual tasks, but illustrate how you might explore different ways of using a cmdlet. Administrators trying out the workflows benefit from some experience with VCF PowerCLI, Microsoft PowerShell, or both.

Examine Depot Contents

You can examine software depots and VIBs with vSphere ESX Image Builder cmdlets by using all kinds of wildcard expressions.

Verify that VCF PowerCLI and prerequisite software is installed. See Configure vSphere ESX Image Builder.

The workflow itself passes parameters by name. However, you can pass parameters as objects by accessing variables.

You can use filtering options and wildcard expressions to examine depot contents.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

   The cmdlet returns one or more `SoftwareDepot` objects.

2. Retrieve image profiles.
   You can filter by vendor, name, and acceptance level.
   - `Get-EsxImageProfiles`

     Returns an array of `ImageProfile` objects from all depots you added to the session.
   - `Get-EsxImageProfile -Vendor "C*"`

     Returns all image profiles created by a vendor with a name that starts with the letter C.
3. Retrieve software packages by using the `Get-EsxSoftwarePackage` cmdlet.
   You can filter, for example by vendor or version, and you can use the standard PowerShell wildcard characters.
   - `Get-EsxSoftwarePackage -Vendor "V*"`

     Returns all software packages from a vendor with a name that starts with the letter V.
   - `Get-EsxSoftwarePackage -Vendor "V*" -Name "*scsi*"`

     Returns all software packages with a name that contains the string `scsi` in it from a vendor with a name that starts with the letter V.
   - `Get-EsxSoftwarePackage -Version "2.0*"`

     Returns all software packages with a version string that starts with 2.0.
4. Use `-Newest` to find the latest package.
   - `Get-EsxSoftwarePackage -Vendor "V*" -Newest`

     Returns the newest package for the vendors with a name that starts with the letter V, and displays the information as a table.
   - `Get-EsxSoftwarePackage -Vendor "V*" -Newest | format-list`

     Returns detailed information about each software package by using a pipeline to link the output of the request for software packages to the PowerShell `format-list` cmdlet.
5. View the list of VIBs in the image profile.
   ```
   (Get-EsxImageProfile -Name "Robin's Profile").VibList
   ```
   `VibList` is a property of the `ImageProfile` object.
6. Retrieve software packages released before or after a certain date by using the `CreatedBefore` or `CreatedAfter` parameter.
   ```
   Get-EsxSoftwarePackage -CreatedAfter 7/1/2020
   ```

   Depot Content Examination Using Variables

   This workflow example examines depot contents by passing in parameters as objects accessed by position in a variable, instead of passing in parameters by name. You can run the following commands in sequence from the VCF PowerCLI prompt. Replace names with names that are appropriate in your installation.

   ```
   Get-EsxSoftwarePackage -Vendor "V*"
   Get-EsxSoftwarePackage -Vendor "V*" -Name "r*"
   Get-EsxSoftwarePackage -Version "2.0*"
   $ip1 = Get-EsxImageProfile -name ESX-9.1.0-123456-full
   $ip1.VibList
   Get-EsxSoftwarePackage -CreatedAfter 7/1/2020
   ```

Create Image Profiles by Cloning Workflow

Use vSphere ESX Image Builder cmdlets to check available depots, add a depot, view image profile information, and to clone a new image profile.

You can use vSphere ESX Image Builder cmdlets to check which depots are available, to add a depot, to view image profile information, and to create a new image profile by cloning one of the available image profiles.

Verify that VCF PowerCLI and prerequisite software is installed. See Configure vSphere ESX Image Builder.

Published profiles are usually read only and cannot be modified. Even if a published profile is not read-only, cloning instead of modifying the profile is a best practice, because modifying the original profile erases the original. You cannot revert to the original, unmodified profile except by reconnecting to a depot.

A profile cloning workflow might include checking the current state of the system, adding a software depot, and cloning the profile.

1. In a PowerShell window, check whether any software depots are defined for the current session.

   ```
   $DefaultSoftwareDepots
   ```

   If you just started PowerShell, it returns the currently defined depots or nothing.

2. If the depot containing the profile that you want to clone does not appear in the results, add it to the current session.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl` *`depot_url`*.
ZIP file	1. Download the ZIP file to a local file path. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\file_path\`*`offline-bundle`*`.zip`

   PowerShell adds the specified depot to your current session and lists all current depots.

3. Optional: Check the `$DefaultSoftwareDepots` variable, which now returns the newly added depot.

4. View all available image profiles.

   ```
   Get-EsxImageProfile
   ```

5. To clone an image profile, enter its name, a new name for the new profile, and a name of the vendor.

   ```
   $ip = New-EsxImageProfile -CloneProfile base-tbd-v1 -Name "Test Profile 42" -Vendor "Vendor20"
   ```

6. Optional: View the newly created image profile, `$ip`.

   PowerShell returns the information about the image profile in tabular format.

   ```
   Name                Vendor          Last Modified          Acceptance Level
   ----                ------          -------------          ----------------
   Test Profile 42     Vendor20        9/15/2020 5:45:43...   PartnerSupported
   ```

   Creating Image Profile by Cloning Using Variables

   This workflow example repeats the steps of this workflow by passing in parameters as objects accessed by position in a variable, instead of passing in parameters by name. You can run the following cmdlets in sequence from the VCF PowerCLI prompt.

   ```
   $DefaultSoftwareDepots
   Add-EsxSoftwareDepot -DepotUrl depot_url
   $DefaultSoftwareDepots
   $profs = Get-EsxImageProfile
   $profs
   $ip = New-EsxImageProfile -CloneProfile $profs[2] -Name "new_profile_name" -Vendor "my_vendor"
   $ip
   ```

Create New Image Profiles Workflow

You can clone an existing image profile or create a new image profile, for which you must define dependencies and acceptance levels.

In most situations, you create an image profile by cloning an existing profile. Some VMware customers or partners might need to create a new image profile. Pay attention to dependencies and acceptance levels if you create an image profile from scratch.

- VCF PowerCLI and prerequisite software is installed. See Configure vSphere ESX Image Builder.

- You have access to a depot that includes a base image and one or more VIBs. VMware and VMware partners have public depots, accessible by a URL. VMware or VMware partners can create a ZIP file that you can unzip to your local environment and access by using a file path.

The system expects that the acceptance level of the VIBs you add to the base image is at least as high as the level of the base image. If you have to add a VIB with a lower acceptance level to the image profile, you must lower the image profile acceptance level. For more information, see Set the Image Profile Acceptance Level.

For string parameters, you can use the PowerShell prompting mechanism as an alternative to specify parameters on the command line. Prompting does not work for other parameters such as objects.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

   The cmdlet returns one or more `SoftwareDepot` objects.

2. Run the `Get-EsxImageProfile` cmdlet to list all image profiles in all currently visible depots. You can narrow your search by using the optional arguments to filter the output.

```
Get-EsxSoftwarePackage -CreatedAfter 7/1/2020
```

3. Create a new profile, assign it a name and vendor, and add a base package.

```
$esxBase = Get-EsxSoftwarePackage 'esx-base'
$vsanHealth = Get-EsxSoftwarePackage 'vsanhealth'

New-EsxImageProfile -NewProfile -Name "Test #2" -Vendor "Vendor42" -SoftwarePackage
 esxBase[0],vsanHealth[0]
```

   The example uses the esx-base package. Names that contain spaces are surrounded by quotes.

   Starting with ESX 8.0 Update 2, removing some VIBs from their Components can cause runtime issues with ESX. For more information, see *Remove VIBs from a Host* topic in the *ESX Upgrade* guide.

4. Use a pipeline to pass the new image profile to `format-list` for detailed information about the new package.

```
(Get-EsxImageProfile -Name "Test #2").VibList | format-list
```

   Creating Image Profiles from Scratch Using Variables

   This command sequence repeats the steps of the workflow, but passes parameters as objects, accessed by position in a variable, instead of passing parameters by name. You can run the following commands in sequence at the VCF PowerCLI prompt.

```
Add-EsxSoftwareDepot depoturl
$pkgs = Get-EsxSoftwarePackage -CreatedAfter 7/1/2020
$ip2 = New-EsxImageProfile -NewProfile -Name "Test #2" -vendor "Vendor42" -SoftwarePackage $pkgs[0]
$ip2.VibList | format-list
```

Edit Image Profiles Workflow

You can create a custom image by cloning and editing an image profile by using VCF PowerCLI.

You can create a custom image by cloning and editing an image profile by using VCF PowerCLI. You can add or remove one or more VIBs in the existing profile. If adding or removing VIBs prevents the image profile from working correctly, an error occurs.

- VCF PowerCLI and prerequisite software is installed. See Configure vSphere ESX Image Builder.

- You have access to a depot that includes a base image and one or more VIBs. VMware and VMware partners make public depots, accessible by a URL, available. VMware or VMware partners can create a ZIP file that you can download to your local environment and access by using a file path.

1. In a PowerCLI session, run the `Add-EsxSoftwareDepot` cmdlet for each depot you want to work with.

Option	Action
Remote depot	Run `Add-EsxSoftwareDepot -DepotUrl <depot_url>`.
ZIP file	1. Download the ZIP file to a local file system. 2. Run `Add-EsxSoftwareDepot -DepotUrl C:\<file_path>\<offline-bundle>.zip`

   The cmdlet returns one or more `SoftwareDepot` objects.

2. Use a pipeline to pass the image profile you intend to edit to `format-list` to see detailed information.

   In this example, the image profile created in Create New Image Profiles Workflow contains only the base image. A newly created image profile is not added to the connected depot(s). It persists for the duration of the session and can be accessed in the list returned by `Get-EsxImageProfile`, by querying for it by name or binding it to a variable at the time it is created.

```
Get-EsxImageProfile "Test #2" | format-list
```

   PowerShell returns the information.

```
Name            : Test #2
Vendor        : Vendor42
...
VibList       : {esx-base 5.0.0.-...,}
```

3. Optional: If you are adding a VIB with a lower acceptance level than that of the image profile, change the acceptance level of the image profile.

```
Set-EsxImageProfile -ImageProfile "Test #2" -AcceptanceLevel VMwareAccepted
```

   PowerShell returns the information about the changed profile in tabular format.

```
Name           Vendor           Last Modified       Acceptance Level
----           ------           -------------       ----------------
Test #2        Vendor42         9/22/2010 12:05:... VMwareAccepted
```

4. Add a software package (VIB) to the image profile. You can add the package by name.

```
Add-EsxSoftwarePackage -ImageProfile "Test #2"
-SoftwarePackage NewPack3
```

   PowerShell returns the information about the image profile in tabular format.

```
Name           Vendor           Last Modified       Acceptance Level
----           ------           -------------       ----------------
Test #2        Vendor42         9/22/2010 12:05:... VMwareAccepted
```

   Note:

   If an error occurs when you add the software package, you might have a problem with acceptance levels, see Working with Acceptance Levels.

5. View the image profile again.

```
Get-EsxImageProfile "Test #2" | format-list
```

   The VIB list is updated to include the new software package and the information is displayed.

```
Name            : Test #2
Vendor        : Vendor42
...
```

```
VibList       : {esx-base 5.0.0.-..., NewPack3}
```

Editing Image Profiles by Using Variables

This cmdlet sequence repeats the steps of the workflow but passes parameters as objects, accessed by position in a variable, instead of passing parameters by name. You can run the following cmdlets in sequence from the VCF PowerCLI prompt.

```
Add-EsxSoftwareDepot -DepotUrl depot_url
$ip2 = Get-EsxImageProfile -name "Test #2"
$ip2 | format-list
Set-EsxImageProfile -ImageProfile $ip2 -AcceptanceLevel VMwareAccepted
Add-EsxImageSoftwarePackage -ImageProfile $ip2 -SoftwarePackage NewPack3
$ip2 | format-list
```

Installing ESX

You can install ESX interactively, with a scripted installation, or with vSphere Auto Deploy.

- Installing ESX Interactively
- Installing or Upgrading Hosts by Using a Script
- Overview of the Network Boot Installation Process
- Installing ESX Using vSphere Auto Deploy

Installing ESX Interactively

Use the interactive installation option for small deployments of fewer than five hosts.

In a typical interactive installation, you boot the ESX installer and respond to the installer prompts to install ESX to the local host disk. The installer reformats and partitions the target disk and installs the ESX boot image. If you have not installed ESX on the target disk before, all data on the drive is overwritten, including hardware vendor partitions, operating system partitions, and associated data.

> **Note:**
> To ensure that you do not lose any data, migrate the data to another machine before you install ESX.

If you are installing ESX on a disk that contains a previous installation of ESX, or a VMFS datastore, the installer provides you with options for upgrading. See the *vSphere Upgrade* documentation.

Interactive ESX Installation

You boot the server from an attached vSphere ESX CD or DVD, or from a bootable USB device, or by PXE booting the server from a location on the network. You follow the prompts in the installation wizard to install ESX to disk.

- Interactive ESX Installation
- Install ESX Interactively
- Install ESX on a Software iSCSI Disk

Install ESX Interactively

You use the ESX CD/DVD or a USB flash drive to install the ESX software onto a SAS, SATA, SCSI hard drive, or USB drive.

- You must have the ESX installer ISO in one of the following locations:
  - On CD or DVD. If you do not have the installation CD/DVD, you can create one. See Download and Burn the ESX Installer ISO Image to a CD or DVD
  - On a USB flash drive. See Format a USB Flash Drive to Boot the ESX Installation or Upgrade.

> **Note:**
> You can also PXE boot the ESX installer to run an interactive installation or a scripted installation. See Network Booting the ESX Installer.

- Verify that the server hardware clock is set to UTC. This setting is in the system BIOS or UEFI.
- Verify that a keyboard and monitor are attached to the machine on which the ESX software is installed. Alternatively, use a remote management application. See Using Remote Management Applications.
- Consider disconnecting your network storage. This action decreases the time that it takes the installer to search for available disk drives. When you disconnect network storage, any files on the disconnected disks are unavailable at installation.

  Do not disconnect a LUN that contains an existing ESX installation. Do not disconnect a VMFS datastore that contains the Service Console of an existing ESX installation. These actions can affect the outcome of the installation.
- Gather the information required by the ESX installation wizard. See *Required Information for ESX Installation*.
- Verify that ESX Embedded is not present on the host machine. ESX Installable and ESX Embedded cannot exist on the same host.

1. Insert the ESX installer CD/DVD into the CD/DVD-ROM drive, or attach the Installer USB flash drive and restart the machine.
2. Set the BIOS or UEFI to boot from the CD-ROM device or the USB flash drive.

   Note:

   If your system has data processing units (DPUs), you can only use UEFI to install and boot ESX on the DPUs.

   See your hardware vendor documentation for information on changing boot order.
3. On the welcome screen, press **Enter** to continue.
4. Accept the End User License Agreement by pressing **Enter**.

   Starting with ESX 8.0 Update 3, after the scanning for available devices completes, if your system has DPUs, you see them automatically listed with their respective PCI slots. You no longer select a slot. The DPU devices must be identical: same vendor, same hardware version, and same firmware.
5. On the **Select a Disk to Install or Upgrade** ESX screen, select the drive on which to install ESX and press **Enter**.

   Press F1 for information about the selected disk.

   Note:
   Do not rely on the disk order in the list to select a disk. The disk order is determined by the BIOS or UEFI and might be out of order. This might occur on systems where drives are continuously being added and removed.

   If you select a disk that contains data, the **Confirm Disk Selection** page appears.

   If you are installing on a disc with a previous ESX or ESX installation or VMFS datastore, the installer provides several choices.

   Important:
   If you are upgrading or migrating an existing ESX installation, see the *VMware ESX Upgrade* documentation.

   If you select a disk that is in vSAN disk group, the resulting installation depends on the type of disk and the group size:

   - If you select an SSD, the SSD and all underlying HDDs in the same disk group are wiped.
   - If you select an HDD, and the disk group size is greater than two, only the selected HDD is wiped.
   - If you select an HDD disk, and the disk group size is two or less, the SSD and the selected HDD is wiped.
6. Select the keyboard type for the host.

   You can change the keyboard type after installation in the direct console.
7. Enter the root password for the host.

   You can change the password after installation in the direct console.
8. In the **Confirm Install** screen, if your vSphere system has DPUs, you see each listed on a separate row. Press `F11` to confirm the start of the installation.

   Starting with 8.0 Update 3, if your systems has DPUs, you see a single progress bar for the ESX and DPU installation, with dynamic updates to the label showing what stage of the installer is being run.

   For more information about managing vSAN disk groups, see the *vSphere Storage* documentation.

If you select an SD or USB device, you see a warning that prompts you to select a persistent disk to store the ESX-OSData partition. In the **Select a Disk to store ESX OSData** screen, select a persistent storage device with minimum 32 GB of available space.

9. When the installation is complete, remove the installation CD, DVD, or USB flash drive.

   Starting with 8.0 Update 3, if the installation is not successful on any of the targets, you see the **Operation Failed** screen. Record the error log in the screen to help troubleshooting.

10. Press **Enter** to reboot the host.
11. Set the first boot device to be the drive on which you installed ESX in step 5.

    For information about changing boot order, see your hardware vendor documentation.

    Note:

    UEFI systems might require additional steps to set the boot device. See Host Fails to Boot After You Install ESX in UEFI Mode.

After the installation is complete, you can migrate existing VMFS data to the ESX host.

You can boot a single machine from each ESX image. Booting multiple devices from a single shared ESX image is not supported.

Set up basic administration and network configuration for ESX. See After You Install and Set Up ESX.

Install ESX on a Software iSCSI Disk

When you install ESX to a software iSCSI disk, you must configure the target iSCSI qualified name (IQN).

- Verify that the target IQN is configured in the iBFT BIOS target parameter setting. This setting is in the option ROM of the network interface card (NIC) to be used for the iSCSI LUN. See the vendor documentation for your system.
- Deactivate the iBFT adapter option to boot to the iSCSI target. This action is necessary to make sure that the ESX installer boots, rather than the iSCSI target. When you start your system, follow the prompt to log in to your iBFT adapter and deactivate the option to boot to the iSCSI target. See the vendor documentation for your system and iBFT adapter. After you finish the ESX installation, you can reenable the option to boot from the LUN you install ESX on.

During system boot, the system performs a Power-On Self Test (POST), and begins booting the adapters in the order specified in the system BIOS. When the boot order comes to the iSCSI Boot Firmware Table (iBFT) adapter, the adapter attempts to connect to the target, but does not boot from it. See Prerequisites.

If the connection to the iSCSI target is successful, the iSCSI boot firmware saves the iSCSI boot configuration in the iBFT. The next adapter to boot must be the ESX installation media, either a mounted ISO image or a physical CD-ROM.

1. Start an interactive installation from the ESX installation CD/DVD or mounted ISO image.
2. On the **Select a Disk** screen, select the iSCSI target you specified in the iBFT BIOS target parameter setting.

   If the target does not appear in this menu, make sure that the TCP/IP and initiator iSCSI IQN settings are correct. Check the network Access Control List (ACL) and confirm that the adapter has adequate permissions to access the target.

3. Follow the prompts to complete the installation.
4. Reboot the host.
5. In the host BIOS settings, enter the iBFT adapter BIOS configuration, and change the adapter parameter to boot from the iSCSI target.

   See the vendor documentation for your system.

On your iBFT adapter, reenable the option to boot to the iSCSI target, so the system will boot from the LUN you installed ESX on.

Installing ESX by Using a Script

The installation/upgrade script is a text file, for example `ks.cfg`, that contains supported commands.

The command section of the script contains the ESX installation options. This section is required and must appear first in the script.

- Scripted ESX Installation
- Installation and Upgrade Scripts Used for ESX Installation
- Configuring External Entropy Sources During Scripted Installation
- Install or Upgrade ESX from a CD or DVD by Using a Script
- Install or Upgrade ESX from a USB Stick by Using a Script
- Network Boot the ESX Installer for a Scripted Installation or Upgrade

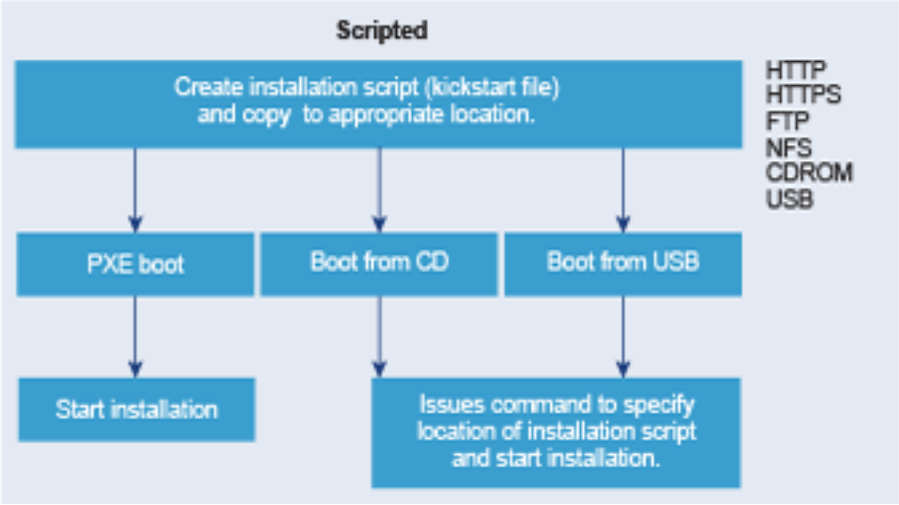
Scripted ESX Installation

Running a script is an efficient way to deploy multiple ESX hosts with an unattended installation.

The installation script contains the host configuration settings. You can use the script to configure multiple hosts with the same settings. See the chapter *Installation and Upgrade Scripts Used for ESX Installation* in the *ESX Upgrade* guide.

The installation script must be stored in a location that the host can access by HTTP, HTTPS, FTP, NFS, CDROM, or USB. You can PXE boot the ESX installer or boot it from a CD/DVD or USB drive.

Figure 3: Scripted Installation



Approaches for Scripted Installation

You can install ESX on multiple machines using a single script for all of them or a separate script for each machine.

For example, because disk names vary from machine to machine, one of the settings that you might want to configure in a script is the selection for the disk to install ESX on.

Table 15: Scripted Installation Choices

Option	Action
Always install on the first disk on multiple machines.	Create one script.
Install ESX on a different disk for each machine.	Create multiple scripts.

For information about the commands required to specify the disk to install on, see Installation and Upgrade Script Commands.

Enter Boot Options to Run an Installation or Upgrade Script

You can start an installation or upgrade script by typing boot options at the ESX installer boot command line.

At boot time you might need to specify options to access the kickstart file. You can enter boot options by pressing Shift+O in the boot loader. For a PXE boot installation, you can pass options through the `kernelopts` line of the `boot.cfg` file. See About the boot.cfg File and Network Booting the ESX Installer.

To specify the location of the installation script, set the `ks=filepath` option, where *`filepath`* indicates the location of your kickstart file. Otherwise, a scripted installation or upgrade cannot start. If `ks=filepath` is omitted, the text installer is run.

Supported boot options are listed in Boot Options .

1. Start the host.
2. When the ESX installer window appears, press `Shift+O` to edit the boot options.
3. At the `runweasel` command prompt, type `ks=`*`location of installation script plus boot command-line options`*.

   Boot Option

   You type the following boot options:

   ```
   ks=http://00.00.00.00/kickstart/ks-osdc-pdp101.cfg nameserver=00.00.0.0 ip=00.00.00.000
    netmask=255.255.255.0 gateway=00.00.00.000
   ```

Boot Options

When you perform a scripted installation, you might need to specify options at boot time to access the kickstart file.

Supported Boot Options

Table 16: Boot Options for ESX Installation

Boot Option	Description
`BOOTIF=`*`hwtype-MAC address`*	Similar to the `netdevice` option, except in the PXELINUX format as described in the IPAPPEND option under SYSLINUX at the `syslinux.org` site.
`gateway=`*`ip address`*	Sets this network gateway as the default gateway to be used for downloading the installation script and installation media.
`ip=`*`ip address`*	Sets up a static IP address to be used for downloading the installation script and the installation media. Note: the PXELINUX format for this option is also supported. See the IPAPPEND option under SYSLINUX at the `syslinux.org` site.
`ks=cdrom:/`*`path`*	Performs a scripted installation with the script at *`path`*, which resides on the CD in the CD-ROM drive. Each CDROM is mounted and checked until the file that matches the path is found. **Important:** If you have created an installer ISO image with a custom installation or upgrade script, you must use uppercase characters to provide the path of the script, for example, `ks=cdrom:/KS_CUST.CFG`.
`ks=file://`*`path`*	Performs a scripted installation with the script at *`path`*.
`ks=`*`protocol`*`://`*`serverpath`*	Performs a scripted installation with a script located on the network at the given URL. *`protocol`* can be `http`, `https`, `ftp`, or `nfs`. An example using NFS protocol is `ks=nfs://`*`host/porturl-path`*. The format of an NFS URL is specified in RFC 2224. **Important:** You must verify the URLs before using them, because the ESX installer does not validate SSL certificates for URLs.

Boot Option	Description
`ks=usb`	Performs a scripted installation, accessing the script from an attached USB drive. Searches for a file named `ks.cfg`. The file must be located in the root directory of the drive. If multiple USB flash drives are attached, they are searched until the `ks.cfg` file is found. Only FAT16 and FAT32 file systems are supported.
`ks=usb:/path`	Performs a scripted installation with the script file at the specified path, which resides on USB.
`ksdevice=device`	Tries to use a network adapter `device` when looking for an installation script and installation media. Specify as a MAC address, for example, `00:50:56:C0:00:01`. This location can also be a `vmnicNN` name. If not specified and files need to be retrieved over the network, the installer defaults to the first discovered network adapter that is plugged in.
`nameserver=ip address`	Specifies a domain name server to be used for downloading the installation script and installation media.
`netdevice=device`	Tries to use a network adapter `device` when looking for an installation script and installation media. Specify as a MAC address, for example, `00:50:56:C0:00:01`. This location can also be a `vmnicNN` name. If not specified and files need to be retrieved over the network, the installer defaults to the first discovered network adapter that is plugged in.
`netmask=subnet mask`	Specifies subnet mask for the network interface that downloads the installation script and the installation media.
`vlanid=vlanid`	Configure the network card to be on the specified VLAN.
`systemMediaSize`	You can use this option to increase the size of system storage partitions on the boot media. The `systemMediaSize` parameter accepts the following values: • default (138 GB) • max (consume all available space, for multi-terabyte servers)

For more information on ESX booting options post installation, see Broadcom knowledge base article 313264.

Installation and Upgrade Scripts Used for ESX Installation

You can use a default script to perform a standard ESX installation to the first detected disk.

During an ESX installation, you can use a default script to perform a standard installation to the first detected disk, and the boot loader configuration file to specify the kernel, the kernel options, and the boot modules that the mboot.c32 or mboot.efi boot loader uses for the installation.

- About the Default ks.cfg Installation Script
- About the boot.cfg File
- Locations Supported for Installation or Upgrade Scripts
- Path to the Installation or Upgrade Script
- Installation and Upgrade Script Commands
- Disk Device Names

About the Default ks.cfg Installation Script

The ESX installer includes a default installation script that performs a standard installation to the first detected disk.

The default `ks.cfg` installation script is located in the initial RAM disk at `/etc/vmware/weasel/ks.cfg`. You can specify the location of the default `ks.cfg` file with the `ks=file://etc/vmware/weasel/ks.cfg` boot option. See Enter Boot Options to Run an Installation or Upgrade Script.

When you install ESX using the `ks.cfg` script, the default root password is `myp@ssw0rd`.

You cannot modify the default script on the installation media. After the installation, you can use the vSphere Client to log in to the vCenter that manages the ESX host and modify the default settings.

With ESX 8.0 and later, if your system has data processing units (DPU), you use the `ks.cfg` script also to install ESX on DPUs.

The default script contains the following commands:

```
#
# Sample scripted installation file
#

# Accept the VMware End User License Agreement
vmaccepteula

# Set the root password for the DCUI and Tech Support Mode
rootpw myp@ssw0rd

# Install on the first local disk available on machine
install --firstdisk --overwritevmfs
 In case you system has DPUs, you also specify a PCI slot:
install --firstdisk --overwritevmfs --dpupcislots=<PCIeSlotID>

# Set the network to DHCP on the first network adapter
network --bootproto=dhcp --device=vmnic0

# A sample post-install script
%post --interpreter=python --ignorefailure=true
import time
stampFile = open('/finished.stamp', mode='w')
stampFile.write( time.asctime() )
```

About the boot.cfg File

The boot loader configuration file `boot.cfg` specifies the kernel, the kernel options, and the boot modules that the `mboot.c32` or `mboot.efi` boot loader uses in an ESX installation.

The `boot.cfg` file is provided in the ESX installer. You can modify the kernelopt line of the `boot.cfg` file to specify the location of an installation script or to pass other boot options.

The `boot.cfg` file has the following syntax:

```
# boot.cfg -- mboot configuration file
#
# Any line preceded with '#' is a comment.

title=STRING
prefix=DIRPATH
kernel=FILEPATH
kernelopt=STRING
modules=FILEPATH1---FILEPATH2... ---FILEPATHn

# Any other line must remain unchanged.
```

The commands in `boot.cfg` configure the boot loader.

Table 17: Commands in boot.cfg

Command	Description
`title=`*`STRING`*	Sets the boot loader title to *`STRING`*.
`prefix=`*`STRING`*	(Optional) Adds *`DIRPATH/`* in front of every *`FILEPATH`* in the `kernel=` and `modules=` commands that do not already start with / or with `http://`.

Command	Description
`kernel=FILEPATH`	Sets the kernel path to *FILEPATH*.
`kernelopt=STRING`	Appends *STRING* to the kernel boot options.
`modules=FILEPATH1 --- FILEPATH2... --- FILEPATHn`	Lists the modules to be loaded, separated by three hyphens (`---`).

See Create an Installer ISO Image with a Custom Installation or Upgrade Script and Network Booting the ESX Installer.

Locations Supported for Installation or Upgrade Scripts

In scripted installations and upgrades, the ESX installer can access the installation or upgrade script, also called the kickstart file, from several locations.

The following locations are supported for the installation or upgrade script:

- CD/DVD. See Create an Installer ISO Image with a Custom Installation or Upgrade Script.
- USB Flash drive. See Create a USB Flash Drive to Store the ESX Installation Script or Upgrade Script.
- A network location accessible through the following protocols: NFS, HTTP, HTTPS, FTP.

Path to the Installation or Upgrade Script

You can specify the path to an installation or upgrade script.

`ks=http://XXX.XXX.XXX.XXX/kickstart/KS.CFG` is the path to the ESX installation script, where*XXX.XXX.XXX.XXX*is the IP address of the machine where the script resides. See Installing ESX by Using a Script.

To start an installation script from an interactive installation, you enter the ks= option manually. See Enter Boot Options to Run an Installation or Upgrade Script.

Installation and Upgrade Script Commands

To modify the default installation or upgrade script or to create your own script, use supported commands. Use supported commands in the installation script, which you specify with a boot command when you boot the installer.

To determine which disk to install or upgrade ESX on, the installation script requires one of the following commands: `install`, `upgrade`, or `installorupgrade`. The `install` command creates the default partitions, including a VMFS datastore that occupies all available space after the other partitions are created.

With ESX 8.0 and later, if your system has supported data processing units (DPU), always consider the installation, re-installation or upgrade of ESX on the DPUs along with ESX on hosts. ESX update and upgrade on DPUs is not supported by the interactive or scripted method, you can only use vSphere Lifecycle Manager.

> **Note:**
> The use of SD and USB devices for storing ESX-OSData partitions is being deprecated. You can use SD and USB devices only to create boot bank partitions, `boot-bank 0` and `boot-bank 1`. Additionally, you can provide a persistent disk of minimum 32 GB on which to install the ESX-OSData partition. You define such disks by using the parameter `systemDisk` in the `install` command.

accepteula or vmaccepteula (Required)

Accepts the ESX license agreement.

> **Note:**
>
> Starting with ESX 9.0, you no longer license ESX hosts by using the vSphere Client. After you license the vCenter instance connected to the ESX hosts, they are licensed automatically. For more information, see Licensing Overview in the *Licensing* guide.

clearpart (Optional)

Clears any existing partitions on the disk. Requires the `install` command to be specified. Carefully edit the `clearpart` command in your existing scripts.

--drives=

Remove partitions on the specified drives.

--alldrives

Ignores the `--drives=` requirement and allows clearing of partitions on every drive.

--ignoredrives=

Removes partitions on all drives except those specified. Required unless the `--drives=` or `--alldrives` flag is specified.

--overwritevmfs

Allows overwriting of VMFS partitions on the specified drives. By default, overwriting VMFS partitions is not allowed.

--firstdisk=
disk-type1
[*disk-type2*,...]

Partitions the first eligible disk found. By default, the eligible disks are set to the following order:

1. Locally attached storage (`local`)
2. Network storage (`remote`)

You can change the order of the disks by using a comma-separated list appended to the argument. If you provide a filter list, the default settings are overridden. You can combine filters to specify a particular disk, including esx for the first disk with ESX installed on it, model and vendor information, or the name of the VMkernel device driver. For example, to prefer a disk with the model name ST3120814A and any disk that uses the mptsas driver rather than a normal local disk, the argument is --firstdisk=ST3120814A,mptsas,local. You can use `localesx` for local storage that contains ESX image or `remoteesx` for remote storage that contains ESX image.

dryrun (Optional)

Parses and checks the installation script. Does not perform the installation.

install

Specifies that this is a fresh installation. Either the `install`, `upgrade`, or `installorupgrade` command is required to determine which disk to install or upgrade ESX on.

--disk= or --drive=

Specifies the disk to partition. In the command `--disk=`*`diskname`*, the *`diskname`* can be a disk name or a full disk filesystem path in ESX, for example:

- Disk name: `--disk=naa.6d09466044143600247aee55ca2a6405` or
- Device path: `--disk=`*`/vmfs/devices/disks/mpx.vmhba1:C0:T0:L0`*

For accepted disk name formats, see Disk Device Names.

--firstdisk=
***disk-type1*,**
[*disk-type2*,...]

Partitions the first eligible disk found. By default, the eligible disks are set to the following order:

1. Locally attached storage (`local`)
2. Network storage (`remote`)

You can change the order of the disks by using a comma-separated list appended to the argument. If you provide a filter list, the default settings are overridden. You can combine filters to specify a particular disk, including esx for

the first disk with ESX installed on it, model and vendor information, or the name of the VMkernel device driver. For example, to prefer a disk with the model name ST3120814A and any disk that uses the mptsas driver rather than a normal local disk, the argument is --firstdisk=ST3120814A,mptsas,local. You can use `localesx` for local storage that contains ESX image or `remoteesx` for remote storage that contains ESX image.

--ignoressd

Excludes solid-state disks from eligibility for partitioning. This option can be used with the `install` command and the --firstdisk option. This option takes precedence over the --firstdisk option. This option is invalid with the --drive or --disk options and with the `upgrade` and `installorupgrade` commands. See the *vSphere Storage* documentation for more information about preventing SSD formatting during auto-partitioning.

--overwritevsan

You must use the --overwritevsan option when you install ESX on a disk, either SSD or HDD (magnetic), that is in a vSAN disk group. If you use this option and no vSAN partition is on the selected disk, the installation fails. When you install ESX on a disk that is in vSAN disk group, the result depends on the disk that you select:

- If you select an SSD, the SSD and all underlying HDDs in the same disk group is wiped.
- If you select an HDD, and the disk group size is greater than two, only the selected HDD is wiped.
- If you select an HDD disk, and the disk group size is two or less, the SSD and the selected HDD is wiped.

For more information about managing vSAN disk groups, see the *vSphere Storage* documentation.

--overwritevmfs

Required to overwrite an existing VMFS datastore on the disk before installation.

--preservevmfs

Preserves an existing VMFS datastore on the disk during installation.

--novmfsondisk

Prevents a VMFS partition from being created on this disk. Must be used with --overwritevmfs if a VMFS partition exists on the disk.

--systemdisk

If you use an USB or SD device, `systemDisk` specifies local persistent disk on which to install the ESX-OSData partition. For example, `install --firstdisk = usb --systemDisk=<diskID>`. As a result, boot bank partitions are placed on the USB device, while the OSData partition is on the disk specified in the `systemDisk` parameter.

--repartitionsystemdisk

If you use an USB or SD device and the local disk that you specify with the `systemDisk` parameter is not empty or contains a datastore, you can use `repartitionSystemDisk` to make sure that the persistent disk is repartitioned before use.

Note:
If a local persistent disk is not available or the disk size is less than 32GB, you see warning messages, but installation continues.

--forceunsupportedinstall

Blocks the installation of deprecated CPUs.

installorupgrade

Either the `install`, `upgrade`, or `installorupgrade` command is required to determine which disk to install or upgrade ESX on.

--disk= or --drive=

Specifies the disk to partition. In the command `--disk=`*`diskname`*, the *`diskname`* can be a disk name or a full disk filesystem path in ESX, for example:

- Disk name: `--disk=naa.6d09466044143600247aee55ca2a6405` or
- Device path: `--disk=`*`/vmfs/devices/disks/mpx.vmhba1:C0:T0:L0`*

For accepted disk name formats, see Disk Device Names.

--firstdisk=
disk-type1,
[*disk-type2*,...]

Partitions the first eligible disk found. By default, the eligible disks are set to the following order:

1. Locally attached storage (`local`)
2. Network storage (`remote`)

You can change the order of the disks by using a comma-separated list appended to the argument. If you provide a filter list, the default settings are overridden. You can combine filters to specify a particular disk, including esx for the first disk with ESX installed on it, model and vendor information, or the name of the VMkernel device driver. For example, to prefer a disk with the model name ST3120814A and any disk that uses the mptsas driver rather than a normal local disk, the argument is --firstdisk=ST3120814A,mptsas,local. You can use `localesx` for local storage that contains ESX image or `remoteesx` for remote storage that contains ESX image.

--overwritevsan

You must use the --overwritevsan option when you install ESX on a disk, either SSD or HDD (magnetic), that is in a vSAN disk group. If you use this option and no vSAN partition is on the selected disk, the installation fails. When you install ESX on a disk that is in a vSAN disk group, the result depends on the disk that you select:

- If you select an SSD, the SSD and all underlying HDDs in the same disk group is wiped.
- If you select an HDD, and the disk group size is greater than two, only the selected HDD is wiped.
- If you select an HDD disk, and the disk group size is two or less, the SSD and the selected HDD is wiped.

For more information about managing vSAN disk groups, see the *vSphere Storage* documentation.

--overwritevmfs

Install ESX if a VMFS partition exists on the disk, but no ESX installation exists. Unless this option is present, the installer fails if a VMFS partition exists on the disk, but anESX installation is missing.

keyboard (Optional)

Sets the keyboard type for the system.

keyboardType

Specifies the keyboard map for the selected keyboard type. *`keyboardType`* must be one of the following types.

- Belgian
- Brazilian
- Croatian
- Czechoslovakian
- Danish
- Estonian
- Finnish
- French
- German
- Greek
- Icelandic
- Italian
- Japanese
- Latin American
- Norwegian
- Polish
- Portuguese
- Russian
- Slovenian
- Spanish

- Swedish
- Swiss French
- Swiss German
- Turkish
- Ukrainian
- United Kingdom
- US Default
- US Dvorak

serialnum or vmserialnum (Optional)

The command is supported in ESX version 5.1 and later. Configures licensing. If not included, ESX installs in evaluation mode.

--esx=<license-key>

> **Note:**
>
> Starting with ESX 9.0, you no longer license ESX hosts by using the vSphere Client. After you license the vCenter instance connected to the ESX hosts, they are licensed automatically. For more information, see Licensing Overview in the *Licensing* guide.

network (Optional)

Specifies a network address for the system.

--bootproto=[dhcp|static]

Specifies whether to obtain the network settings from DHCP or set them manually.

--device=

Specifies either the MAC address of the network card or the device name, in the form `vmnicNN`, as in `vmnic0`. This option refers to the uplink device for the virtual switch.

--ip=

Sets an IP address for the machine to be installed, in the form `xxx.xxx.xxx.xxx`. Required with the --bootproto=static option and ignored otherwise.

--gateway=

Designates the default gateway as an IP address, in the form `xxx.xxx.xxx.xxx`. Used with the --bootproto=static option.

--nameserver=

Designates the primary name server as an IP address. Used with the `--bootproto=static` option. Omit this option if you do not intend to use DNS.

The `--nameserver` option can accept two IP addresses. For example: `--nameserver="10.126.87.104[,10.126.87.120]"`

--netmask=

Specifies the subnet mask for the installed system, in the form `255.xxx.xxx.xxx`. Used with the `--bootproto=static` option.

--hostname=

Specifies the host name for the installed system.

--vlanid= ***`vlanid`***

Specifies which VLAN the system is on. Used with either the --bootproto=dhcp or `--bootproto=static` option. Set to an integer from 1 to 4095.

--addvmportgroup=(0|1)

Specifies whether to add the VM Network port group, which is used by virtual machines. The default value is 1.

paranoid (Optional)

Causes warning messages to interrupt the installation. If you omit this command, warning messages are logged.

part or partition (Optional)

Creates an extra VMFS datastore on the system. Only one datastore per disk can be created. Cannot be used on the same disk as the `install` command. Only one partition can be specified per disk and it can only be a VMFS partition.

datastore name

Specifies where the partition is to be mounted.

--ondisk= or --ondrive=

Specifies the disk or drive where the partition is created.

--onfirstdisk=
disk-type1,
[*disk-type2*,...]

Partitions the first eligible disk found. By default, the eligible disks are set to the following order:

1. Locally attached storage (`local`)
2. Network storage (`remote`)

You can change the order of the disks by using a comma-separated list appended to the argument. If you provide a filter list, the default settings are overridden. You can combine filters to specify a particular disk, including esx for the first disk with ESX installed on it, model and vendor information, or the name of the VMkernel device driver. For example, to prefer a disk with the model name ST3120814A and any disk that uses the mptsas driver rather than a normal local disk, the argument is --onfirstdisk=ST3120814A,mptsas,local. You can use `localesx` for local storage that contains ESX image or `remoteesx` for remote storage that contains ESX image.

reboot (Optional)

Reboots the machine after the scripted installation is complete.

<--noeject>

The CD is not ejected after the installation.

rootpw (Required)

Sets the root password for the system.

--iscrypted

Specifies that the password is encrypted.

password

Specifies the password value.

upgrade

Either the `install`, `upgrade`, or `installorupgrade` command is required to determine which disk to install or upgrade ESX on.

--disk= or --drive=

Specifies the disk to partition. In the command `--disk=`*`diskname`*, the *`diskname`* can be a disk name or a full disk filesystem path in ESX, for example:

- Disk name: `--disk=naa.6d09466044143600247aee55ca2a6405` or
- Device path: `--disk=`*`/vmfs/devices/disks/mpx.vmhba1:C0:T0:L0`*

For accepted disk name formats, see Disk Device Names.

--firstdisk=
disk-type1,
[*disk-type2*,...]

Partitions the first eligible disk found. By default, the eligible disks are set to the following order:

1. Locally attached storage (`local`)
2. Network storage (`remote`)

You can change the order of the disks by using a comma-separated list appended to the argument. If you provide a filter list, the default settings are overridden. You can combine filters to specify a particular disk, including esx for the first disk with ESX installed on it, model and vendor information, or the name of the VMkernel device driver. For example, to prefer a disk with the model name ST3120814A and any disk that uses the mptsas driver rather than a normal local disk, the argument is --firstdisk=ST3120814A,mptsas,local. You can use `localesx` for local storage that contains ESX image or `remoteesx` for remote storage that contains ESX image.

%include or include (Optional)

Specifies another installation script to parse. This command is treated similarly to a multiline command, but takes only one argument.

filename

For example: `%include part.cfg`

%pre (Optional)

Specifies a script to run before the kickstart configuration is evaluated. For example, you can use it to generate files for the kickstart file to include.

--interpreter
=[python|busybox]

Specifies an interpreter to use. The default is busybox.

%post (Optional)

Runs the specified script after package installation is complete. If you specify multiple `%post` sections, they run in the order that they appear in the installation script.

--interpreter
=[python|busybox]

Specifies an interpreter to use. The default is busybox.

--timeout=secs

Specifies a timeout for running the script. If the script is not finished when the timeout expires, the script is forcefully stopped.

--ignorefailure
=[true|false]

If true, the installation is considered a success even if the `%post` script stops with an error.

%firstboot

Creates an `init` script that runs only during the first boot. The script has no effect on subsequent boots. If multiple `%firstboot` sections are specified, they run in the order that they appear in the kickstart file.

Note:
You cannot check the semantics of `%firstboot` scripts until the system is booting for the first time. A `%firstboot` script might contain potentially catastrophic errors that are not exposed until after the installation is complete.

Important:
The `%firstboot` script does not run, if secure boot is enabled on the ESX host.

--interpreter
=[python|busybox]

Specifies an interpreter to use. The default is busybox.

Note:
You cannot check the semantics of the `%firstboot` script until the system boots for the first time. If the script contains errors, they are not exposed until after the installation is complete.

Disk Device Names

The `install`, `upgrade`, and `installorupgrade` installation script commands require the use of disk device names.

Table 18: Disk Device Names

Format	Example	Description
NAA	naa.6d09466044143600247aee55ca2a6405	SCSI INQUIRY identifier
EUI	eui.3966623838646463	SCSI INQUIRY identifier
T10	t10.SanDisk00Cruzer_Blade000000004C5300011711 18101244	SCSI INQUIRY identifier
VML	vml.00025261	Legacy VMkernel identifier
MPX	mpx.vmhba0:C0:T0:L0	Path-based identifier

You can use the `esxcli storage core device list` command to display all device names in the vSphere CLI. The output is similar to the following example:

```
# esxcli storage core device list
naa.XXX
   Display Name: DGC Fibre Channel Disk(naa.XXX)
   ...
   Other UIDs: vml.000XXX
mpx.vmhba1:C0:T0:L0
   Display Name: Local VMware Disk (mpx.vmhba1:C0:T0:L0)
   ...
   Other UIDs: vml.0000000000XYZ
```

For more information on storage device names, see ESX Storage Device Names and Identifiers in the *vSphere Storage* documentation.

Install or Upgrade ESX from a CD or DVD by Using a Script

You can install or upgrade ESX from a CD-ROM or DVD-ROM drive by using a script that specifies the installation or upgrade options.

Before you run the scripted installation or upgrade, verify that the following prerequisites are met:

- The system on which you are installing or upgrading meets the hardware requirements. See ESX Hardware Requirements.
- You have the ESX installer ISO on an installation CD or DVD. See Download and Burn the ESX Installer ISO Image to a CD or DVD.
- The default installation or upgrade script (`ks.cfg`) or a custom installation or upgrade script is accessible to the system. See Installing ESX by Using a Script.
- You have selected a boot command to run the scripted installation or upgrade. See Enter Boot Options to Run an Installation or Upgrade Script. For a complete list of boot commands, see Boot Options .

You can start the installation or upgrade script by entering a boot option when you start the host. You can also create an installer ISO image that includes the installation script. With an installer ISO image, you can perform a scripted,

unattended installation when you boot the resulting installer ISO image. See Create an Installer ISO Image with a Custom Installation or Upgrade Script.

1. Boot the ESX installer from the local CD-ROM or DVD-ROM drive.
2. When the ESX installer window appears, press `Shift+O` to edit boot options.
3. Type a boot option that calls the default installation or upgrade script or an installation or upgrade script file that you created.

   The boot option has the form `ks=`.
4. Press Enter.

The installation, upgrade, or migration runs, using the options that you specified.

Install or Upgrade ESX from a USB Stick by Using a Script

You can install or upgrade ESX from a USB flash drive by using a script that specifies the installation or upgrade options.

Before running the scripted installation or upgrade, verify that the following prerequisites are met:

- The system that you are installing or upgrading to ESX meets the hardware requirements for the installation or upgrade. See ESX Hardware Requirements.
- You have the ESX installer ISO on a bootable USB flash drive. See Format a USB Flash Drive to Boot the ESX Installation or Upgrade.
- The default installation or upgrade script (`ks.cfg`) or a custom installation or upgrade script is accessible to the system. See Installing ESX by Using a Script.
- You have selected a boot option to run the scripted installation, upgrade, or migration. See Enter Boot Options to Run an Installation or Upgrade Script.

Supported boot options are listed in Boot Options .

1. Boot the ESX installer from the USB flash drive.
2. When the ESX installer window appears, press `Shift+O` to edit boot options.
3. Type a boot option that calls the default installation or upgrade script or an installation or upgrade script file that you created.

   The boot option has the form `ks=`.
4. Press Enter.

The installation, upgrade, or migration runs, using the options that you specified.

Network Boot the ESX Installer for a Scripted Installation or Upgrade

ESX 9.1 provides many options for booting the installer over a network and using an installation or upgrade script.

- For information about setting up a network infrastructure, see Network Booting the ESX Installer.
- For information about creating and locating an installation script, see Installing ESX by Using a Script.
- For specific procedures to network boot the ESX installer and use an installation script, see one of the following topics:
  - Boot the ESX Installer by Using Native UEFI HTTP
  - Boot the ESX Installer by Using iPXE and HTTP
  - Boot the ESX Installer by Using PXE and TFTP
- For information about using vSphere Auto Deploy to perform a scripted installation by using PXE to boot, see Installing ESX Using vSphere Auto Deploy.

Configuring External Entropy Sources During Scripted Installation

Starting with ESX 8.0 Update 1, you can configure external entropy sources in the kickstart file for scripted installation.

You can configure ESX in a highly secure environment to consume entropy from external entropy sources, such as a Hardware Security Module (HSM), and align with standards such as BSI Common criteria, EAL4, and NIST FIPS CMVP, by using the scripted installation method.

Starting with ESX 8.0 Update 1, a new entropy daemon, `entropyd`, is active and creates a vAPI endpoint to provide REST API to query and send entropy data to ESX hosts. The entropy daemon has several configurable parameters: `memory-cache size`, `storage-cache size`, `memory-low watermark`, and `entropy-lost-timeout`. The entropy daemon forwards entropy received from external devices to the VMkernel entropy pool.

If you do not need to select external entropy sources, you do not need to change anything in your existing scripts.

You can configure external entropy sources only for new installations. The entropy daemon uses entropy data passed during installation at first boot.

Note:

You cannot use any other method, such as interactive install, a cluster image, or Auto Deploy, to configure external entropy sources. You cannot enable the feature on an existing ESX host.

Before you update the kickstart file, you must:

- Get legitimate binary entropy data from an external source such as HSM.
- Save this data as a file of size between 512 KB to 10 MB, for example, `entropy_data.dat`.
- Encode the contents of the `entropy_data` file in a valid base64 format to create another file, for example `entropy_data.b64`.

In the kickstart file, you provide the following new parameters as part of the `entropy` command:

- `data` - the base64-encoded entropy data from an external source.
- `sources` - This bitmask value is set in the kernel settings during install time. The bitmask value is a 4-bits value:
  - binary(0000) = decimal(0) = default (all sources except entropyd if RDSEED is not supported, or FIPS-compliant sources if RDSEED is supported)
  - binary(0001) = decimal(1) = interrupts
  - binary(0010) = decimal(2) = RDRAND
  - binary(0100) = decimal(4) = RDSEED
  - binary(1000) = decimal(8) = entropyd (external entropy source)

  Source values are combined using bitwise OR operations: To enable multiple sources, sum the values. For example, if you combine RDSEED and entropyd, the calculation is 0100 | 1000 = 1100 or 4 + 8 = 12 in decimal, so you must use `entropySources=12`.

  If you decide to enable all entropy sources, then calculation is 0001 | 0010 | 0100 | 1000 = 1111 or 1+2+4+8 = 15 in decimal. The valid decimal range is 0-15.

  For EAL4 compliance, `8` is the only required value. Source values persist as a kernel setting during installation.

Note:

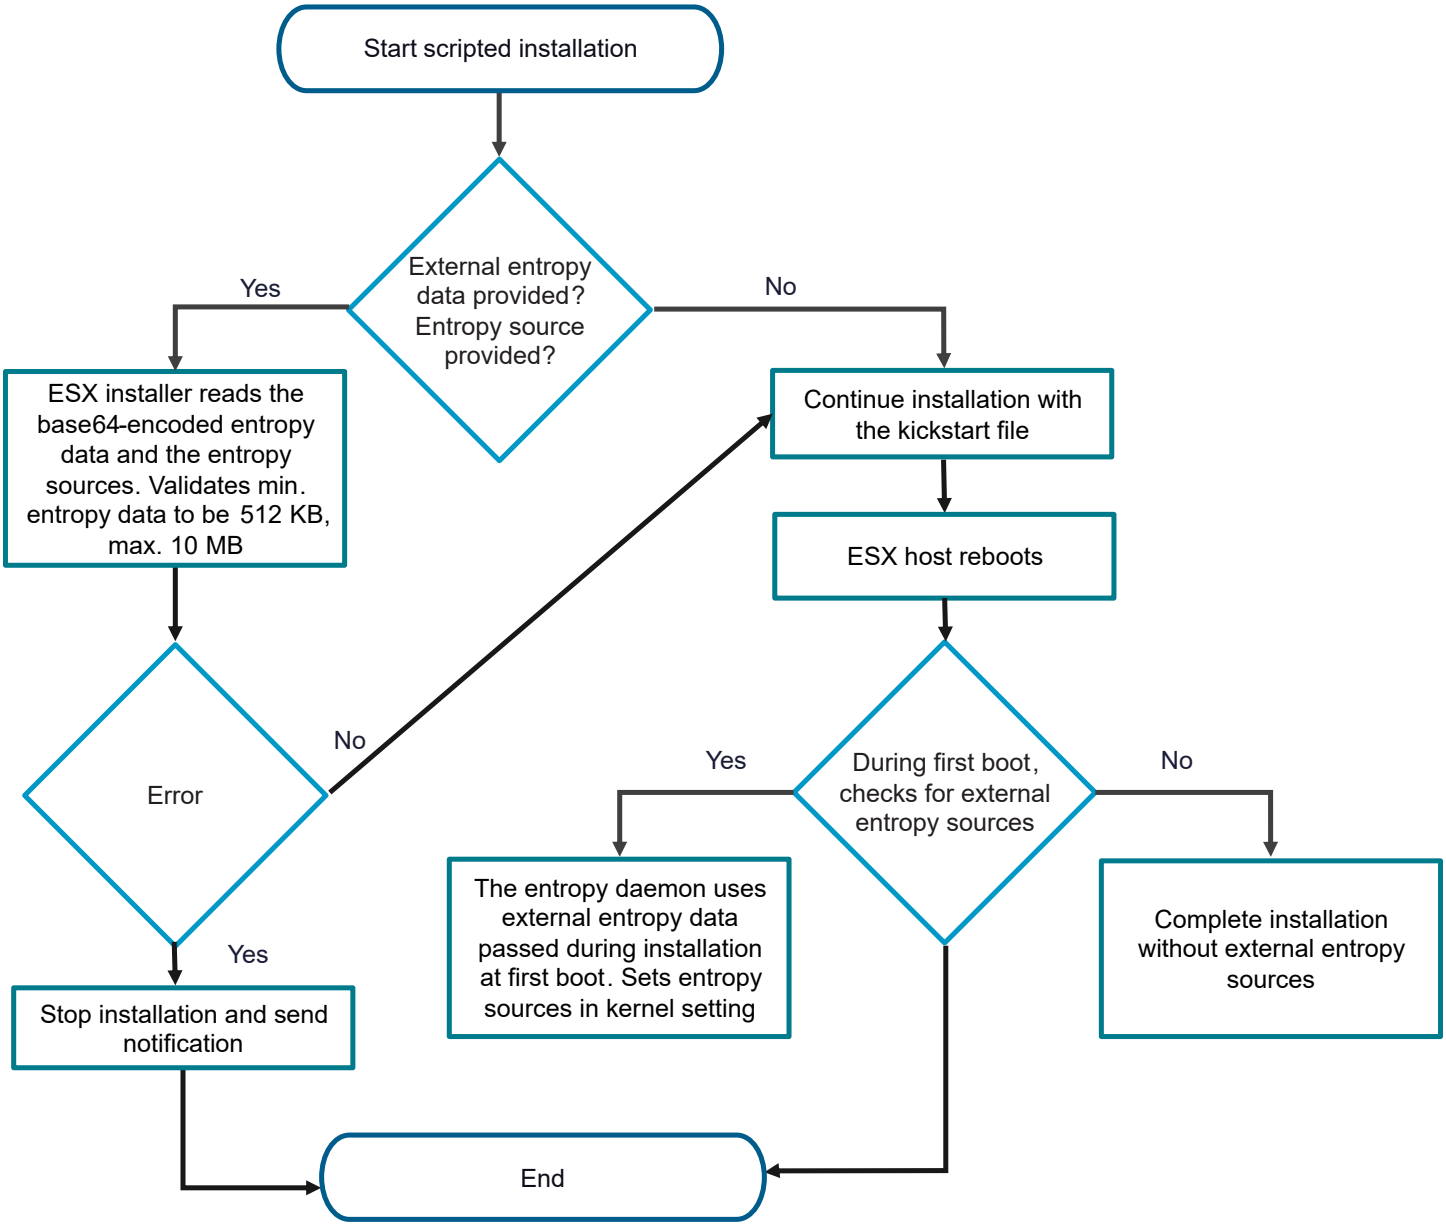
If you configure an ESX host with exteral entropy sources only, that is when the `sources` value is set to `8`, you must keep supplying external entropy to the host by using the entropy API. If external entropy is exhausted in the host, the host becomes unresponsive and it might require a hard reboot or re-installation to recover the host from such a situation.

If the ESX host is unresponsive even after a hard reset, you must boot the host with multiple entropy sources to recover.

A sample kickstart with the entropy parameters:

```
vmaccepteula
rootpw xxxxxxxx
entropy --sources=8 --data=xxxxxxx/xx/xxxxx/xx/xxxx...
install --firstdisk --overwritevmfs
network --bootproto=dhcp
```

Figure 4: Scripted installation workflow for adding external entropy sources



After installation completes, you can log in to the ESX host and define some parameters for the entropy daemon from the shell by using the following ESXCLI commands:

ESXCLI commands

1. Get Commands

##	esxcli system entropyd get	Command Description
1	`<no argument>`	Get currently configured and default values of all `entropyd` parameters
2	`--default-values`	Get default values

2. Set Commands

##	esxcli system entropyd set	Command Description
1	`--help`	Print details of "esxcli system entropyd set" command and it's arguments

2	`--reset=all`
	`--reset=memory-cache-size`
	`--reset=memory-cache-low-watermark`
	`--reset=storage-cache-size`
	`--reset=external-entropy-lost-timeout`
		Reset a parameter or all parameters to its default values.

3	`--memory-cache-size=` <value in KiB>	Set memory cache size in KiB.
4	`--memory-cache-low-watermark=` <value in %>	Set memory cache low water mark in percentage.
5	`--storage-cache-size=`<value in KiB>	Set storage cache size in KiB.
6	`--external-entropy-lost-timeout=` <value in seconds>	Set external entropy lost timeout in seconds.

Example:

```
$ esxcli system entropyd set --external-entropy-lost-timeout=70 --memory-cache-low-watermark=30 --memory-
cache-size=612 --storage-cache-size=5096
$ esxcli system entropyd get
External Entropy Lost Timeout Seconds: 70
Memory Cache Low Watermark Percentage: 30
Memory Cache Size Kibibytes: 612
Storage Cache Size Kibibytes: 5096

$ esxcli system entropyd get --default-values
External Entropy Lost Timeout Seconds: 60
Memory Cache Low Watermark Percentage: 20
Memory Cache Size Kibibytes: 512
Storage Cache Size Kibibytes: 4096
```

During installation, the ESX installer updates the entropy sources value in the kernel settings so that it persists in the ConfigStore after the installation. This change does not affect secure booting of ESX hosts.

Verification, monitoring, and troubleshooting

To check configured entropy sources, use the command `esxcli system settings kernel list -o entropySources`.

For troubleshooting, you can examine the following logs:

- Entropyd logs: `/var/run/log/entropyd.log`

- Installer logs: `/var/log/esxi_install.log`
- VMkernel logs for resource pool and vmkaccess violation: `/var/run/log/vmkernel.log`

You can also use VMkernel Observation (VOBs), which are kernel messages with unique identifier, to check for entropy alerts under **Monitor > Tasks and Events > Events** in the VMware Host Client. Alternatively, you can check entropy alerts in the ESX console by pressing `Alt+F11`.

For more information, see the vSphere Security and vSphere Automation SDKs Programming guides.

Network Booting the ESX Installer

If your host uses legacy BIOS or UEFI, you can use preboot execution environment (PXE) to boot an ESX host from a network device.

Alternatively, if your ESX host supports native UEFI HTTP, you can use hypertext transfer protocol (HTTP) to boot the host from a network device. ESX is distributed in an ISO format that is used to install to flash memory or to a local hard drive. You can extract the files and boot them over a network interface.

PXE uses Dynamic Host Configuration Protocol (DHCP) and Trivial File Transfer Protocol (TFTP) to boot an operating system over a network.

PXE booting requires some network infrastructure and a machine with a PXE-capable network adapter. Most machines that can run ESX have network adapters that can PXE boot.

Native UEFI HTTP uses DHCP and HTTP to boot over a network. UEFI HTTP boot requires a network infrastructure, UEFI firmware version on the ESX host that includes HTTP boot feature, and a network adapter that supports UEFI networking.

Booting by using HTTP is faster and more reliable than using TFTP. This is due to the capabilities of the TCP protocol that underlies the HTTP, such as built-in streaming and lost packet recovery. If your ESX hosts do not support native UEFI HTTP, you can use iPXE HTTP for the boot process.

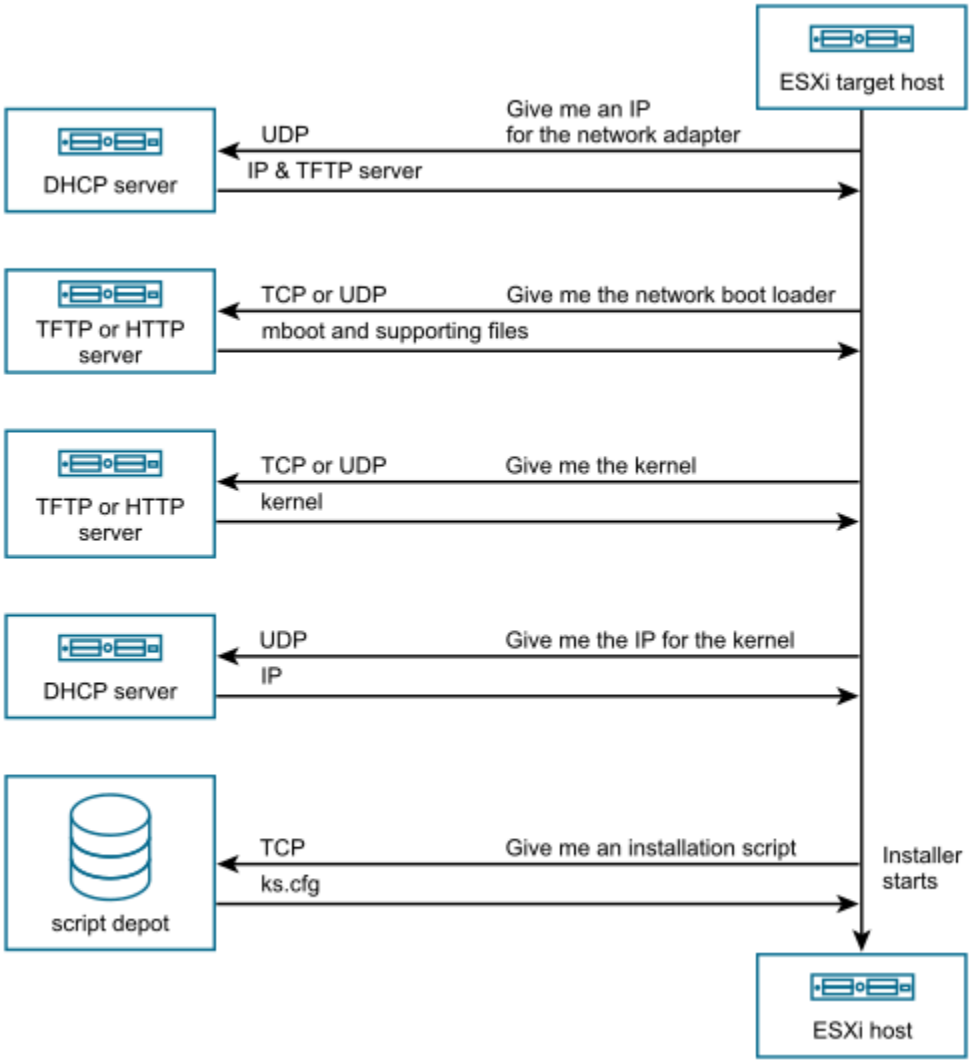
> **Note:**
> Network booting with legacy BIOS firmware is possible only over IPv4. Network booting with UEFI BIOS firmware is possible over IPv4 or IPv6.

Overview of the Network Boot Installation Process

You can boot an ESX host from a network interface. The network boot process varies depending on whether the target host is using legacy BIOS or UEFI firmware, and whether the boot process uses PXE TFTP, iPXE HTTP, or UEFI HTTP.

When you boot a target host, it interacts with the different servers in the environment to get a network adapter, boot loader, kernel, IP address for the kernel, and finally an installation script. When all components are in place, installation starts, as shown in the following illustration.

Figure 5: Overview of PXE Boot Installation Process



The interaction between the ESX host and other servers proceeds as follows:

1. The user boots the target ESX host.
2. The target ESX host makes a DHCP request.
3. The DHCP server responds with the IP information, the location of the TFTP or HTTP server, and the filename or URL of the initial network boot loader.
4. The ESX host contacts the TFTP or HTTP server and requests the filename or URL that the DHCP server specified.
5. The TFTP or HTTP server sends the network boot loader, and the ESX host runs it. The initial boot loader might load additional boot loader components from the server.
6. The boot loader searches for a configuration file on the TFTP or HTTP server, downloads the kernel and other ESX components as specified in the configuration file, and boots the kernel on the ESX host.
7. The installer runs interactively or using a kickstart script, as specified in the configuration file.

Network Boot Background Information

Understanding the network boot process can help you during troubleshooting.

TFTP Server

Trivial File Transfer Protocol (TFTP) is similar to the FTP service, and is typically used only for network booting systems or loading firmware on network devices such as routers. TFTP is available on Linux and Windows.

- Most Linux distributions include a copy of the tftp-hpa server. If you require a supported solution, purchase a supported TFTP server from your vendor of choice. You can also acquire a TFTP server from one of the packaged appliances on the VMware Marketplace.
- If your TFTP server runs on a Microsoft Windows host, use tftpd32 version 2.11 or later. See http://tftpd32.jounin.net/.

SYSLINUX and PXELINUX

If you are using PXE in a legacy BIOS environment, you must understand the different boot environments.

- SYSLINUX is an open-source boot environment for machines that run legacy BIOS firmware. The ESX boot loader for BIOS systems, `mboot.c32`, runs as a SYSLINUX plugin. You can configure SYSLINUX to boot from several types of media, including disk, ISO image, and network. You can find the SYSLINUX package at http://www.kernel.org/pub/linux/utils/boot/syslinux/.
- PXELINUX is a SYSXLINUX configuration for booting from a TFTP server according to the PXE standard. If you use PXELINUX to boot the ESX installer, the `pxelinux.0` binary file, `mboot.c32`, the configuration file, the kernel, and other files are transferred by TFTP.

  Note:
  VMware builds the `mboot.c32` plugin to work with SYSLINUX version 3.86 and tests PXE booting only with that version. Other versions might be incompatible. *The Open Source Disclosure Package for VMware vSphere Hypervisor* includes bug fixes for SYSLINUX version 3.86.

iPXE

iPXE is open-source software that provides an implementation of HTTP. You can use the software to perform an initial boot. For more information, see https://ipxe.org/.

VMware includes a build of iPXE as part of Auto Deploy. The source tree for this build is available in *The Open Source Disclosure Package for VMware vCenter*.

UEFI PXE and UEFI HTTP

Most UEFI firmware natively includes PXE support that allows booting from a TFTP server. The firmware can directly load the ESX boot loader for UEFI systems, `mboot.efi`. Additional software such as PXELINUX is not required.

Some UEFI firmware support native UEFI HTTP boot. The feature is introduced in version 2.5 of the UEFI specification. The firmware can load the ESX boot loader from an HTTP server, without additional software, such as iPXE.

Note:
Apple Macintosh products do not include PXE boot support. They include support for network booting through an Apple-specific protocol instead.

Alternative Approaches to Network Booting

Alternative approaches to network booting different software on different hosts are also possible, for example:

- Configuring the DHCP server to provide different initial boot loader filenames to different hosts depending on MAC address or other criteria. See your DCHP server's documentation.
- Approaches using iPXE as the initial bootloader with an iPXE configuration file that selects the next bootloader based on the MAC address or other criteria.

PXELINUX Configuration Files

You need a PXELINUX configuration file to boot the ESX installer on a legacy BIOS system. The configuration file defines the menu displayed to the target ESX host as it starts.

This section gives general information about PXELINUX configuration files.

For syntax details, see the SYSLINUX website at http://www.syslinux.org/.

Required Files

In the PXE configuration file, you must include paths to the following files:

- `mboot.c32` is the boot loader.
- `boot.cfg` is the boot loader configuration file.

See About the boot.cfg File

Filename for the PXE Configuration File

For the filename of the PXE configuration file, select one of the following options:

- `01-mac_address_of_target_ESX_host`. For example, `01-23-45-67-89-0a-bc`
- The target ESX host IP address in a hexadecimal notation.
- `default`

The initial boot file `pxelinux.0` tries to load a PXE configuration file in the following order:

1. It tries with the MAC address of the target ESX host, prefixed with its ARP type code, which is 01 for Ethernet.
2. If that attempt fails, it tries with the hexadecimal notation of target ESX system IP address.
3. Ultimately, it tries to load a file named `default`.

File Location for the PXE Configuration File

Save the file in `/tftpboot/pxelinux.cfg/` on the TFTP server.

For example, you might save the file on the TFTP server at `/tftpboot/pxelinux.cfg/01-00-21-5a-ce-40-f6`. The MAC address of the network adapter on the target ESX host is 00-21-5a-ce-40-f6.

Boot the ESX Installer by Using PXE and TFTP

You can use a TFTP server to PXE boot the ESX installer. The process differs slightly depending on whether you use UEFI or boot from a legacy BIOS.

Because most environments include ESX hosts that support UEFI boot and hosts that support only legacy BIOS, this topic discusses prerequisites and steps for both types of hosts.

Verify that your environment meets the following prerequisites.

- ESX installer ISO image, downloaded from the Broadcom Support Portal.
- Target host with a hardware configuration that is supported for your version of ESX. See the Broadcom Compatibility Guide.
- Network adapter with PXE support on the target ESX host.
- DHCP server that you can configure for PXE booting. See Sample DHCP Configurations.
- TFTP server.
- Network security policies to allow TFTP traffic (UDP port 69).
- For legacy BIOS, you can use only IPv4 networking. For UEFI PXE boot, you can use IPv4 or IPv6 networking.
- (Optional) Installation script (kickstart file).
- Use a native VLAN in most cases. If you want to specify the VLAN ID to be used with PXE booting, check that your NIC supports VLAN ID specification.

For legacy BIOS systems, obtain version 3.86 of the SYSLINUX package. For more information, see Network Boot Background Information.

- For legacy BIOS machines, the procedure supports booting multiple different versions of the ESX installer by using the same `pxelinux.0` initial boot loader for all target machines, but potentially different PXELINUX configuration files depending on the target machine's MAC address.
- For UEFI machines, the procedure supports booting multiple different versions of the ESX installer by using the same `mboot.efi` initial boot loader for all target machines, but potentially different `boot.cfg` files depending on the target machine's MAC address.

1. If your ESX host runs legacy BIOS firmware only, obtain and configure PXELINUX.
   a) Obtain SYSLINUX version 3.86, unpack it, and copy the `pxelinux.0` file to the top-level `/tftpboot` directory on your TFTP server.
   b) Create a PXELINUX configuration file using the following code model.

      ESX `-9.x.x-XXXXXX` is the name of the TFTP subdirectory that contains the ESX installer files.

      ```
      DEFAULT install
      NOHALT 1
      LABEL install
        KERNEL ESX-9.x.x-XXXXXX/mboot.c32
        APPEND -c ESX-9.x.x-XXXXXX/boot.cfg
        IPAPPEND 2
      ```

   c) Save the PXELINUX file in the `/tftpboot/pxelinux.cfg` directory on your TFTP server with a filename that will determine whether all hosts boot this installer by default:

Option	Description
Same installer	Name the file `default` if you want all host to boot this ESX installer by default.
Different installers	Name the file with the MAC address of the target host machine (01-*mac_address_of_target_ESX_host*) if you want only a specific host to boot with this file, for example, `01-23-45-67-89-0a-bc`.

2. If your ESX host runs UEFI firmware, copy the `efi/boot/bootx64.efi` and `efi/boot/crypto64.efi` files from the ESX installer ISO image to the `/tftpboot` folder on your TFTP server.
3. Rename the `efi/boot/bootx64.efi` file to `mboot.efi`.

   Note:
   Newer versions of `mboot.efi` can generally boot older versions of ESX, but older versions of `mboot.efi` might be unable to boot newer versions of ESX. If you plan to configure different hosts to boot different versions of the ESX installer, use the `mboot.efi` from the newest version.
4. Configure the DHCP server.
5. Create a subdirectory of your TFTP server's top-level `/tftpboot` directory and name it after the version of ESX it will hold, for example, `/tftpboot/ESX-9.x.x-xxxxx`.
6. Copy the contents of the ESX installer image to the newly created directory.
7. Modify the `boot.cfg` file
   a) Add the following line:

      ```
      prefix=ESX-9.x.x-xxxxxx
      ```

      Here, `ESX-9.x.x-xxxxxx` is the pathname of the installer files relative to the TFTP server's root directory.
   b) If the filenames in the `kernel=` and `modules=` lines begin with a forward slash (/) character, delete that character.
   c) If the `kernelopt=` line contains the string `cdromBoot`, remove the string only.
8. Optional: For a scripted installation, in the `boot.cfg` file, add the `kernelopt` option to the line after the kernel command, to specify the location of the installation script.

   Use the following code as a model, where `XXX.XXX.XXX.XXX` is the IP address of the server where the installation script resides, and `esxi_ksFiles` is the directory that contains the `ks.cfg` file.

   ```
   kernelopt=ks=http://XXX.XXX.XXX.XXX/esxi_ksFiles/ks.cfg
   ```

9. If your ESX host runs UEFI firmware, specify whether you want all UEFI hosts to boot the same installer.

Option	Description
Same installer	Copy or link the `boot.cfg` file to `/tftpboot/boot.cfg`
Different installers	1. Create a subdirectory of `/tftpboot` named after the MAC address of the target host machine

Option	Description
	(01-*mac_address_of_target_ESX_host*), for example, `01-23-45-67-89-0a-bc`. 2. Place a copy of (or a link to) the host's `boot.cfg` file in that directory, for example, `/tftpboot/01-23-45-67-89-0a-bc/boot.cfg`.

Boot the ESX Installer by Using iPXE and HTTP

You can use iPXE to boot the ESX installer from an HTTP server.

The prerequisites and steps depend on the support of UEFI boot or legacy BIOS only. You can use iPXE to boot the ESX installer from an HTTP server. The following topic discusses prerequisites and steps for ESX hosts that support UEFI boot and hosts that support legacy BIOS only.

Verify that your environment has the following components:

- ESX installer ISO image, downloaded from the Broadcom Support Portal.
- Target host with a hardware configuration that is supported for your version of ESX. See the *Broadcom Compatibility Guide*.
- Network adapter with PXE support on the target ESX host.
- DHCP server that you can configure for PXE booting. See Sample DHCP Configurations.
- TFTP server.
- Network security policies to allow TFTP traffic (UDP port 69).
- For legacy BIOS, you can use only IPv4 networking. For UEFI PXE boot, you can use IPv4 or IPv6 networking.
- (Optional) Installation script (kickstart file).
- Use a native VLAN in most cases. If you want to specify the VLAN ID to be used with PXE booting, check that your NIC supports VLAN ID specification.

Verify that your environment also meets the following prerequisites required for PXE boot using an HTTP Server:

- Verify that the HTTP server is accessible by your target ESX hosts.
- If your ESX host runs legacy BIOS firmware only, obtain version 3.86 of the SYSLINUX package. For more information, see Network Boot Background Information.
- For legacy BIOS machines, the procedure supports booting multiple different versions of the ESX installer by using the same `pxelinux.0` initial boot loader for all target machines, but potentially different PXELINUX configuration files depending on the target machine's MAC address.
- For UEFI machines, the procedure supports booting multiple different versions of the ESX installer by using the same `mboot.efi` initial boot loader for all target machines, but potentially different `boot.cfg` files depending on the target machine's MAC address.

1. Obtain and configure iPXE.
   a) Obtain the iPXE source code.
   b) On the iPXE download page, follow the build instructions, but run one of the following commands.
      - For ESX hosts that run legacy BIOS firmware only, run `make bin/undionly.kpxe`.
      - For ESX hosts that run UEFI firmware, run `make bin-x86_64-efi/snponly.efi`.
   c) Copy the `undionly.kpxe` or `snponly.efi` file to the `/tftpboot` directory on your TFTP server.
2. If your ESX host runs legacy BIOS firmware only, obtain and configure PXELINUX.
   a) Obtain SYSLINUX version 3.86, unpack it, and copy the `pxelinux.0` file to the `/tftpboot` directory on your TFTP server.
   b) Create a PXELINUX configuration file using the following code model.

      `ESX-9.x.x-XXXXXX` is the name of the TFTP subdirectory that contains the ESX installer files.

      ```
      DEFAULT install
      NOHALT 1
      LABEL install
        KERNEL ESX-9.x.x-XXXXXX/mboot.c32
      ```

```
APPEND -c ESX-9.x.x-XXXXXX/boot.cfg
IPAPPEND 2
```

c) Save the PXELINUX file in the `/tftpboot/pxelinux.cfg` directory on your TFTP server.
The filename determines whether all hosts boot this installer by default.

Option	Description
Same installer	Name the file `default` if you want all host to boot this ESX installer by default.
Different installers	Name the file with the MAC address of the target host machine (01-*mac_address_of_target_ESX_host*), if only a specific host must boot this file. For example, `01-23-45-67-89-0a-bc`.

3. If your ESX host runs UEFI firmware, copy the `efi/boot/bootx64.efi` file from the ESX installer ISO image to the `/tftpboot` folder on your TFTP server, and rename the file to `mboot.efi`.

   Note:
   Newer versions of `mboot.efi` can generally boot older versions of ESX, but older versions of `mboot.efi` might be unable to boot newer versions of ESX. If you plan to configure different hosts to boot different versions of the ESX installer, use the `mboot.efi` from the newest version.

4. Configure the DHCP server.
5. Create a directory on your HTTP server with the same name as the version of ESX it will hold. For example, `/var/www/html/ESX-9.x.x-XXXXXX`.
6. Copy the contents of the ESX installer image to the newly created directory.
7. Modify the `boot.cfg` file.
   a) Add the following line:
   ```
   prefix=http://XXX.XXX.XXX.XXX/ESX-9.x.x-XXXXXX
   ```
   where `http://XXX.XXX.XXX.XXX/ESX-9.x.x-XXXXXX` is the location of the installer files on the HTTP server.
   b) If the filenames in the `kernel=` and `modules=` lines begin with a forward slash (/) character, delete that character.
   c) If the `kernelopt=` line contains the string `cdromBoot`, remove the string only.
8. Optional: For a scripted installation, in the `boot.cfg` file, add the `kernelopt` option to the line after the kernel command, to specify the location of the installation script.
   Use the following code as a model, where `XXX.XXX.XXX.XXX` is the IP address of the server where the installation script resides, and `esxi_ksFiles` is the directory that contains the `ks.cfg` file.
   ```
   kernelopt=ks=http://XXX.XXX.XXX.XXX/esxi_ksFiles/ks.cfg
   ```
9. If your ESX host runs UEFI firmware, specify whether you want all UEFI hosts to boot the same installer.

Option	Description
Same installer	Copy or link the `boot.cfg` file to `/tftpboot/boot.cfg`
Different installers	1. Create a subdirectory of `/tftpboot` named after the MAC address of the target host machine (01-*mac_address_of_target_ESX_host*), for example, `01-23-45-67-89-0a-bc`. 2. Place a copy of (or a link to) the host's `boot.cfg` file in that directory, for example, `/tftpboot/01-23-45-67-89-0a-bc/boot.cfg`.

Boot the ESX Installer by Using Native UEFI HTTP

You can boot the ESX installer directly from an HTTP server, without additional software to support the process.

Verify that your environment has the following components:

- ESX host with UEFI firmware that supports the HTTP boot feature.

  - ESX installer ISO image, downloaded from the Broadcom Support Portal.
  - Target host with a hardware configuration that is supported for your version of ESX. See the Broadcom Compatibility Guide.
- Network adapter with UEFI networking support on the target ESX host.
- DHCP server that you can configure for UEFI HTTP booting. See Sample DHCP Configurations.
  - (Optional) Installation script (kickstart file)
  - Use a native VLAN in most cases. If you want to specify the VLAN ID to be used with HTTP(S) Booting, check that your NIC supports VLAN ID specification.

UEFI HTTP supports booting multiple versions of the ESX installer. You use the same `mboot.efi` initial boot loader for all target machines, but potentially different `boot.cfg` files depending on the MAC address os the target machine.

Note:
Do not mix IPv4 or IPv6 networking during the boot process. Use either IPv4 or IPv6 networking.

1. Copy the `efi/boot/bootx64.efi` file from the ESX installer ISO image to a directory on your HTTP server and rename the file to `mboot.efi`. For example, `http://www.example.com/esx/mboot.efi`.

   Note:
   Newer versions of `mboot.efi` can generally boot older versions of ESX, but older versions of `mboot.efi` might be unable to boot newer versions of ESX. If you plan to configure different hosts to boot different versions of the ESX installer, use the `mboot.efi` from the newest version.

2. Configure the DHCP server.
3. Create a directory on your HTTP server with the same name as the version of ESX it holds. For example, `http://www.example.com/esx/ESX-9.x.x-XXXXXX`.
4. Copy the contents of the ESX installer image to the newly created directory.
5. Modify the `boot.cfg` file.
   a) Add the following line with the URL of the newly created directory.

      ```
      prefix=http://www.example.com/esx/ESX-9.x.x-XXXXXX
      ```

   b) If the filenames in the `kernel=` and `modules=` lines begin with a forward slash (/) character, delete that character.
   c) If the `kernelopt=` line contains the string `cdromBoot`, remove the string only.
6. Optional: For a scripted installation, in the `boot.cfg` file, add the `kernelopt` option to the line after the kernel command, to specify the location of the installation script.

   For example, `kernelopt=ks=http://www.example.com/esx_ksFiles/ks.cfg`
7. Optional: You can use the virtual machine configuration parameters *`networkBootProtocol`* and *`networkBootUri`* to specify from where a virtual machines can boot. The setting *`networkBootProtocol`* specifies the boot protocol, IPv4 or IPv6. For example, `networkBootProtocol = httpv4`. The setting *`networkBootUri`* specifies the HTTP URL to the ESX bootloader (bootx64.efi). For example, `networkBootUri = http://xxx.xxx.xx.x/esx9.xxxx/efi/boot/bootx64.efi`.
8. Specify whether you want all UEFI hosts to boot the same installer.

Option	Description
Same installer	Add the `boot.cfg` file to the same directory as `mboot.efi`. For example, `http://www.example.com/esx/boot.cfg`
Different installers	1. Create a subdirectory of the directory that contains the `mboot.efi` file. Name the directory as the MAC address of the target host machine (01-*`mac_address_of_target_ESX_host`*), for example, `01-23-45-67-89-0a-bc`. 2. Add the custom `boot.cfg` file in the directory. For example, `http://www.example.com/esx/01-23-45-67-89-0a-bc/boot.cfg`.

You can use both installer types. ESX hosts without custom `boot.cfg` file on your HTTP server, boot from the default `boot.cfg` file.

Sample DHCP Configurations

The DHCP server must send the address of the TFTP or HTTP server and the filename of the initial boot loader to the ESX host.

When the target machine first boots, it broadcasts a packet across the network requesting information to boot itself. The DHCP server responds. The DHCP server must be able to determine whether the target machine is allowed to boot and the location of the initial boot loader binary. For PXE boot, the location is a file on a TFTP server. For UEFI HTTP boot, the location is a URL.

> **CAUTION:**
> Do not set up a second DHCP server if your network already has one. If multiple DHCP servers respond to DHCP requests, machines can obtain incorrect or conflicting IP addresses, or can fail to receive the proper boot information. Talk to a network administrator before setting up a DHCP server. For support on configuring DHCP, contact your DHCP server vendor.

There are many DHCP servers that you can use. The following examples are for an ISC DHCP server. If you are using a version of DHCP for Microsoft Windows, see the DHCP server documentation to determine how to pass the next-server and filename arguments to the target machine.

Example of Booting Using PXE and TFTP with IPv4

This example shows how to configure an ISC DHCP server to PXE boot ESX using a TFTP server at IPv4 address `xxx.xxx.xxx.xxx`.

```
#
# ISC DHCP server configuration file snippet.  This is not a complete
# configuration file; see the ISC server documentation for details on
# how to configure the DHCP server.
#
allow booting;
allow bootp;
option client-system-arch code 93 = unsigned integer 16;
class "pxeclients" {
   match if substring(option vendor-class-identifier, 0, 9) = "PXEClient";
   next-server xxx.xxx.xxx.xxx;
   if option client-system-arch = 00:07 or option client-system-arch = 00:09 {
      filename = "mboot.efi";
   } else {
      filename = "pxelinux.0";
   }
}
```

When a machine attempts to PXE boot, the DHCP server provides an IP address and the location of the `pxelinux.0` or `mboot.efi` binary file on the TFTP server.

Example of Booting Using PXE and TFTP with IPv6

This example shows how to configure an ISC DHCPv6 server to PXE boot ESX using a TFTP server at IPv6 address xxxx:xxxx:xxxx:xxxx::xxxx.

```
#
# ISC DHCPv6 server configuration file snippet.  This is not a complete
# configuration file; see the ISC server documentation for details on
# how to configure the DHCP server.
#
```

```
allow booting;
allow bootp;
option dhcp6.bootfile-url code 59 = string;
option dhcp6.bootfile-url "tftp://[xxxx:xxxx:xxxx:xxxx::xxxx]/mboot.efi";
```

When a machine attempts to PXE boot, the DHCP server provides an IP address and the location of the `mboot.efi` binary file on the TFTP server.

Example of Booting Using iPXE and HTTP with IPv4

This example shows how to configure an ISC DHCP server to boot ESX by loading iPXE from a TFTP server at IPv4 address `xxx.xxx.xxx.xxx`.

```
#
# ISC DHCP server configuration file snippet.  This is not a complete
# configuration file; see the ISC server documentation for details on
# how to configure the DHCP server.
#
allow booting;
allow bootp;
option client-system-arch code 93 = unsigned integer 16;
class "pxeclients" {
   match if substring(option vendor-class-identifier, 0, 9) = "PXEClient";
   next-server xxx.xxx.xxx.xxx;
   if option client-system-arch = 00:07 or option client-system-arch = 00:09 {
      if exists user-class and option user-class = "iPXE" {
         # Instruct iPXE to load mboot.efi as secondary bootloader
         filename = "mboot.efi";
      } else {
         # Load the snponly.efi configuration of iPXE as initial bootloader
         filename = "snponly.efi";
      }
   } else {
      if exists user-class and option user-class = "iPXE" {
         # Instruct iPXE to load pxelinux as secondary bootloader
         filename = "pxelinux.0";
      } else {
         # Load the undionly configuration of iPXE as initial bootloader
         filename = "undionly.kpxe";
   }
}
```

When a machine attempts to PXE boot, the DHCP server provides an IP address and the location of the `undionly.kpxe` or `snponly.efi` binary file on the TFTP server. In the legacy BIOS case, iPXE then asks the DHCP server for the next file to load, and the server returns `pxelinux.0` as the filename. In the UEFI case, iPXE then asks the DHCP server for the next file to load, and this time the server returns `mboot.efi` as the filename. In both cases, iPXE is resident and the system has HTTP capability. As a result, the system can load additional files from an HTTP server.

Example of Booting Using iPXE and HTTP with IPv6

This example shows how to configure an ISC DHCPv6 server to boot ESX by loading iPXE from a TFTP server at IPv6 address `xxxx:xxxx:xxxx:xxxx::xxxx`.

```
#
# ISC DHCPv6 server configuration file snippet. This is not a complete
# configuration file; see the ISC server documentation for details on
# how to configure the DHCP server.
#
allow booting;
```

```
allow bootp;

option dhcp6.bootfile-url code 59 = string;
if exists user-class and option user-class = "iPXE" {
   # Instruct iPXE to load mboot.efi as secondary bootloader
   option dhcp6.bootfile-url "tftp://[xxxx:xxxx:xxxx:xxxx::xxxx]/mboot.efi";
} else {
   # Load the snponly.efi configuration of iPXE as initial bootloader
   option dhcp6.bootfile-url "tftp://[xxxx:xxxx:xxxx:xxxx::xxxx]/snponly.efi";
}
```

When a machine attempts to PXE boot, the DHCP server provides an IP address and the location of the `snponly.efi` (iPXE) binary file on the TFTP server. iPXE then asks the DHCP server for the next file to load, and this time the server returns `mboot.efi` as the filename. iPXE is resident and the system has HTTP capability. As a result, the system can load additional files from an HTTP server.

Example of Booting Using UEFI HTTP with IPv4

This example shows how to configure an ISC DHCP server to boot ESX by using native UEFI HTTP over IPv4 from Web server `www.example.com`.

```
#
# ISC DHCP server configuration file snippet. This is not a complete
# configuration file; see the ISC server documentation for details on
# how to configure the DHCP server.
#
allow booting;
allow bootp;
option client-system-arch code 93 = unsigned integer 16;
class "httpclients" {
   match if substring(option vendor-class-identifier, 0, 10) = "HTTPClient";
   option vendor-class-identifier "HTTPClient";

   if option client-system-arch = 00:10 {
      # x86_64 UEFI HTTP client
      filename = http://www.example.com/esx/mboot.efi;
   }
}
```

Example of Booting Using UEFI HTTP with IPv6

This example shows how to configure an ISC DHCPv6 server to boot ESX by using native UEFI HTTP over IPv6 from Web server `www.example.com`.

```
#
# ISC DHCPv6 server configuration file snippet. This is not a complete
# configuration file; see the ISC server documentation for details on
# how to configure the DHCP server.
#
allow booting;
allow bootp;

option dhcp6.bootfile-url code 59 = string;
option dhcp6.user-class code 15 = { integer 16, string };
option dhcp6.vendor-class code 16 = { integer 32, integer 16, string };

if option dhcp6.client-arch-type = 00:10 {
      # x86_64 HTTP clients
      option dhcp6.vendor-class 0 10 "HTTPClient";
```

```
        option dhcp6.bootfile-url "http://www.example.com/esx/mboot.efi";
}
```

Installing ESX Using vSphere Auto Deploy

vSphere Auto Deploy lets you provision hundreds of physical hosts with ESX software.

Using Auto Deploy, experienced system administrators can manage large deployments efficiently. Hosts are network-booted from a central Auto Deploy server. Optionally, hosts are configured with a host profile of a reference host. The host profile can be set up to prompt the user for input. After boot up and configuration complete, the hosts are managed by vCenter just like other ESX hosts.

Important:

The vSphere Host Profiles capability is deprecated in ESX 9.0 and will be removed in a future release. Instead of Host profiles, you can use vSphere Configuration Profiles to manage configurations at cluster level.

Auto Deploy can also be used for stateless caching or stateful installations.

Important:
Auto Deploy requires a secure separation between the production network and the management or deployment networks as discussed in vSphere Auto Deploy Security Considerations. Using Auto Deploy without this separation is insecure.

Stateless caching	By default, Auto Deploy does not store ESX configuration or state on the host disk. Instead, an image profile defines the image that the host is provisioned with, and other host attributes are managed through host profiles. A host that uses Auto Deploy for stateless caching still needs to connect to the Auto Deploy server and the vCenter.
Stateful installs	You can provision a host with Auto Deploy and set up the host to store the image to a disk. On subsequent boots, the host boots from the disk.

Understanding vSphere Auto Deploy

vSphere Auto Deploy can provision hundreds of physical hosts with ESX software.

You can specify the image to deploy and the hosts to provision with the image. Optionally, you can specify host profiles to apply to the hosts, a vCenter location (datacenter, folder, or cluster), and assign a script bundle for each host.

- Introduction to vSphere Auto Deploy
- Rules and Rule Sets

Introduction to vSphere Auto Deploy

vSphere Auto Deploy uses network boot infrastructure with host profiles, a desired image, or vSphere Configuration Profiles to provision ESX hosts.

State Information for ESX Hosts

Note:
You cannot use Auto Deploy on ESX hosts configured with DPUs as part of the vSphere Distributed Services Engine feature.

When you start a physical host that is set up for vSphere Auto Deploy, vSphere Auto Deploy uses PXE boot infrastructure in conjunction with vSphere Host Profiles, a vSphere Lifecycle Manager desired image, or vSphere Configuration Profiles to provision and customize that host. No state is stored on the host itself. Instead, the vSphere Auto Deploy server manages state information for each host. vSphere Auto Deploy stores the information for the ESX hosts to be provisioned in different locations. Information about the location of image profiles, host profiles, or clusters that you manage by either a single image or by a configuration on a cluster level is initially specified in the rules that map machines to image profiles and host profiles.

Important:

The vSphere Host Profiles capability is deprecated in ESX 9.0 and will be removed in a future release. Instead of Host profiles, you can use vSphere Configuration Profiles to manage configurations at cluster level.

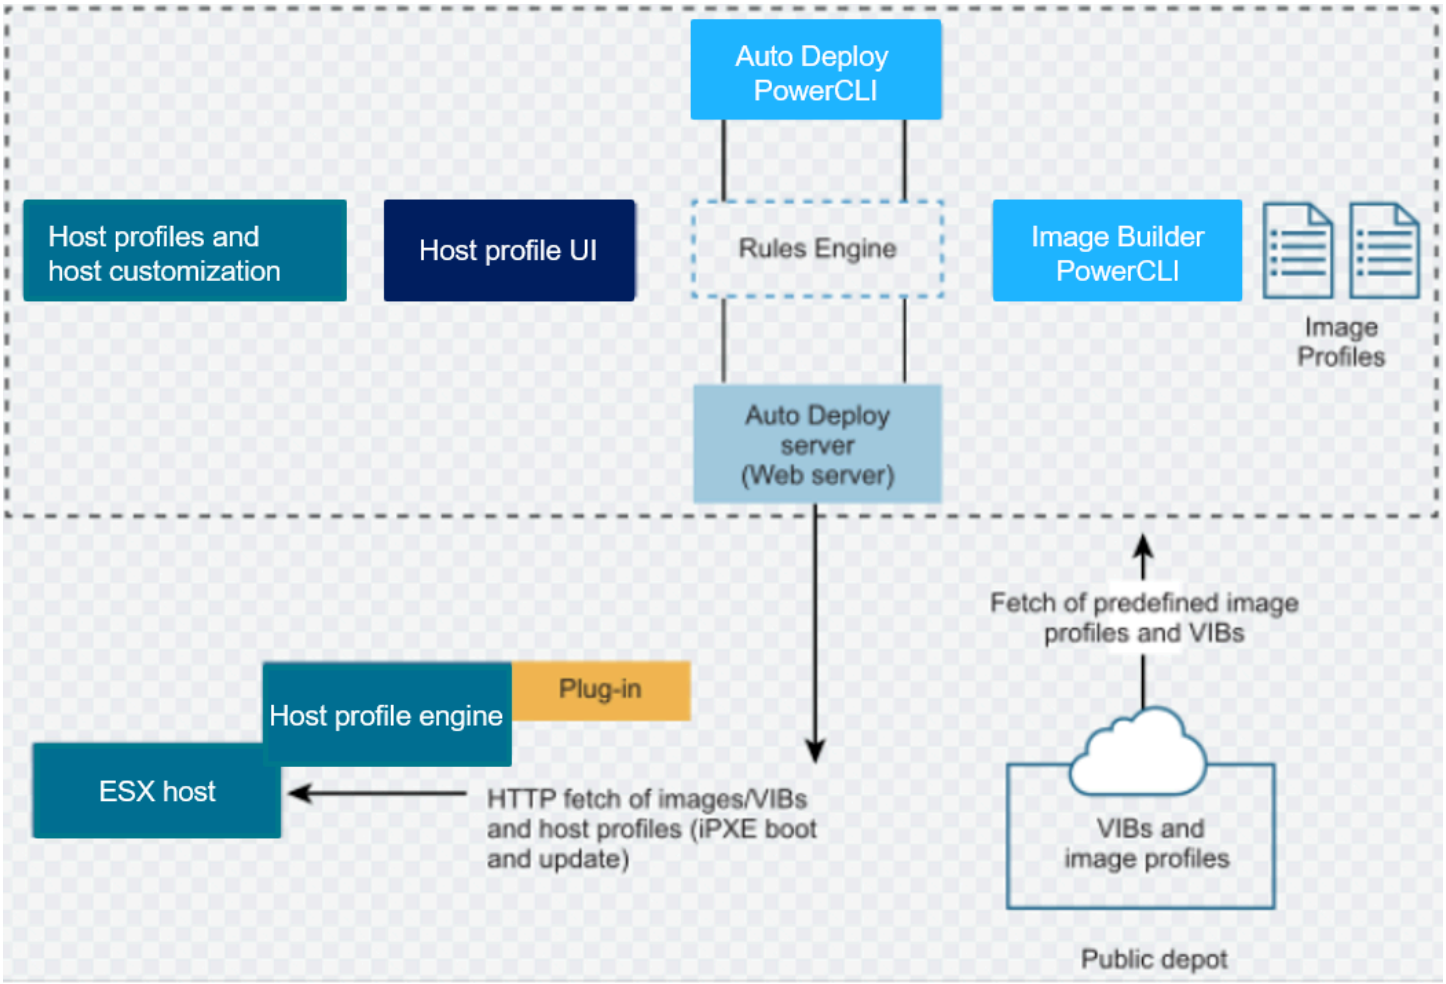
Table 19: vSphere Auto Deploy Stores Information for Deployment

Information Type	Description	Source of Information
Image state	The executable software to run on an ESX host.	Image profile, created with vSphere ESX Image Builder or a vSphere Lifecycle Manager image.
Configuration state	The configurable settings that determine how the host is configured, for example, virtual switches and their settings, driver settings, boot parameters, and so on.	Host profiles, created by using the vSphere Client, or a configuration that you create when setting up a cluster that manages all ESX host settings at a cluster level, such as vSphere Configuration Profiles.
Dynamic state	The runtime state that is generated by the running software, for example, generated private keys or runtime databases.	Host memory, lost during reboot.
Virtual machine state	The virtual machines stored on a host and virtual machine autostart information (subsequent boots only).	Virtual machine information sent by vCenter to vSphere Auto Deploy must be available to supply virtual machine information to vSphere Auto Deploy.
User input	State that is based on user input, for example, an IP address that the user provides when the system starts up, cannot automatically be included in the host profile.	Host customization information, stored by vCenter during first boot. You can create a host profile that requires user input for certain values. When vSphere Auto Deploy applies a host profile that requires user provided information, the host is placed in maintenance mode. In the vSphere Client, check the host profile compliance, and respond to the prompt to customize the host.

vSphere Auto Deploy Architecture

The vSphere Auto Deploy infrastructure consists of several components.

Figure 6: vSphere Auto Deploy Architecture



vSphere Auto Deploy server	Serves images and host profiles to ESX hosts.
vSphere Auto Deploy rules engine	Sends information to the vSphere Auto Deploy server which image profile and which host profile to serve to which host. Administrators use vSphere Auto Deploy to define the rules that assign image profiles and host profiles to hosts. For more information on vSphere Auto Deploy rules and rule sets, see Rules and Rule Sets. Apart from legacy image profiles that you create by using the VMware Image Builder and host profiles, you can also create vSphere Auto Deploy rules to deploy ESX by using a single vSphere Lifecycle Manager image or vSphere Configuration Profiles.
Image profiles	Define the set of VIBs with which to boot ESX hosts.

	• Broadcom and Broadcom partners make image profiles and VIBs available in public depots. Use vSphere ESX Image Builder to examine the depot and use the vSphere Auto Deploy rules engine to specify which image profile to assign to which host. • You use vSphere Lifecycle Manager images to apply software and firmware updates to the ESX hosts in a cluster. Using a single image to manage all hosts in a cluster ensures cluster-wide host image homogeneity. • Starting with ESX 8.0, you can also use vSphere Configuration Profiles to manage the configuration of all hosts in a cluster. • You can create a custom image profile based on the public image profiles and VIBs in the depot and apply that image profile to the host. See Customizing Installations with vSphere ESX Image Builder. •
Host profiles	Define machine-specific configuration such as networking or storage setup. Use the host profile UI to create host profiles. You can create a host profile for a reference host and apply that host profile to other hosts in your environment for a consistent configuration. For more information, see the *vSphere Host Profiles* documentation or the Setting Up a vSphere Auto Deploy Reference Host section.
Host customization	Stores information that the user provides when host profiles are applied to the host. Host customization might contain an IP address or other information that the user supplied for that host. For more information about host customizations, see the *vSphere Host Profiles* documentation. Host customization was called answer file in earlier releases of vSphere Auto Deploy.

Auto Deploy Certificates

By default, the Auto Deploy server provisions each host with certificates that are signed by the VMware Certificate Authority (VMware CA). For more information, see the *Managing Certificates for ESX Hosts* in the *vSphere Security* guide.

Alternatively, if your corporate policy requires that you use custom certificates, you can set up the Auto Deploy server to provision all hosts with custom certificates that are not signed by VMware CA. The Auto Deploy server becomes a subordinate certificate authority of your third-party CA. In the Custom Certificate Authority mode, you are responsible for managing the certificates. You cannot refresh and renew certificates from the vSphere Client. In this mode, you also cannot select only a set of hosts to provision with custom certificates, and you can manually sign custom certificates only for stateful hosts. For more information, see *Use Custom Certificates with Auto Deploy* in the *vSphere Security* guide.

Auto Deploy provides a third option that allows you to generate a certificate outside vSphere and become independent of the certificate management in vCenter. For example, you can generate a custom certificate by using a custom script or by using a provider of domain name registry services such as Verisign. You can use custom certificates for only a set of ESX hosts. You can provide custom certificates for stateless hosts as well. ESX hosts are identified by the MAC address of the NIC used for network booting, or the BIOS UUID of the ESX host. You update the VMware Endpoint Certificate Store (VECS) with the custom certificate by using VCF PowerCLI. For more information on the new VCF PowerCLI cmdlets, see How vSphere Auto Deploy Works with VCF PowerCLI. The VMware CA must trust the custom ESX certificates so you must add the CA public certificate for the custom certificates to the TRUSTED_ROOTS store in VECS. Auto Deploy also stores the custom certificates and when it recognizes a booting host with the respective MAC address of the NIC used for network booting, or the BIOS UUID of the ESX host, it automatically provides the custom certificate. You do not need to stop or restart Auto Deploy or vCenter when you add a custom certificate to VECS, only restart the host for which you upload a custom certificate. For more information, see *Use Custom Certificates with Auto Deploy* in the *vSphere Security* guide.

Rules and Rule Sets

You specify the behavior of the vSphere Auto Deploy server by using a set of rules. The vSphere Auto Deploy rules engine checks the rule set for matching host patterns to decide which items (image profile, host profile, vCenter location, or script object) to provision each host with.

The rules engine maps software and configuration settings to hosts based on the attributes of the host. For example, you can deploy image profiles or host profiles to two clusters of hosts by writing two rules, each matching on the network address of one cluster.

For hosts that have not yet been added to a vCenter system, the vSphere Auto Deploy server checks with the rules engine before serving image profiles, host profiles, and inventory location information to hosts. For hosts that are

managed by a vCenter system, the image profile, host profile, and inventory location that vCenter has stored in the host object is used. If you make changes to rules, you can use the vSphere Client or vSphere Auto Deploy cmdlets in a VCF PowerCLI session to test and repair rule compliance. When you repair rule compliance for a host, that host's image profile and host profile assignments are updated.

Note:

Auto Deploy can merge rules to complete a configuration. For example, if you have three rules, one specifying only an image, another only a cluster, and a third one with a configuration, if an ESX host matches the 3 rules, it can get the image from the first, the cluster from the second, and the configuration from the third rule. This is useful when you aim to write fewer rules for larger deployments, where all clusters in a RAC can get a configuration from several rules rather than creating complete rules for each cluster.

The rules engine includes rules and rule sets.

Rules

Rules can assign image profiles and host profiles to a set of hosts, or specify the location (folder or cluster) of a host on the target vCenter system. A rule can identify target hosts by boot MAC address, SMBIOS information, BIOS UUID, Vendor, Model, or fixed DHCP IP address. In most cases, rules apply to multiple hosts. You create rules by using the vSphere Client or vSphere Auto Deploy cmdlets in a VCF PowerCLI session. After you create a rule, you must add it to a rule set. Only two rule sets, the active rule set and the working rule set, are supported. A rule can belong to both sets, the default, or only to the working rule set. After you add a rule to a rule set, you can no longer change the rule. Instead, you copy the rule and replace items or patterns in the copy. If you are managing vSphere Auto Deploy with the vSphere Client, you can edit a rule if it is in inactive state.

You can specify the following parameters in a rule.

Parameter	Description
Name	Name of the rule, specified with the `-Name` parameter.
Item	One or more items, specified with the `-Item` parameter. An item can be an image profile, a host profile, a vCenter inventory location (datacenter, folder, cluster) for the target host, or a custom script. You can specify multiple items separated by commas.
Pattern	The pattern specifies the host or group of hosts to which the rule applies. **vendor** Machine vendor name. **model** Machine model name. **serial** Machine serial number. **hostname** Machine hostname. **domain** Domain name. **UUID** The Universally Unique Identifier. **ipv4** IPv4 address of the machine. **Gateway IPV4** A Gateway IPv4 address. **ipv6** IPv6 address of the machine. PXE booting with BIOS firmware is possible only with IPv4, PXE booting with UEFI firmware is possible with either IPv4 or IPv6. **mac** Boot NIC MAC address. **asset** Machine asset tag. **oemstring** OEM-specific strings in the SMBIOS. You can specify `-AllHosts` to apply the item or items to all hosts.

Active Rule Set

When a newly started host contacts the vSphere Auto Deploy server with a request for an image profile, the vSphere Auto Deploy server checks the active rule set for matching rules. The image profile, host profile, vCenter inventory location, and script object that are mapped by matching rules are then used to boot the host. If more than one item of the same type is mapped by the rules, the vSphere Auto Deploy server uses the item that is first in the rule set.

Working Rule Set

The working rule set allows you to test changes to rules before making the changes active. For example, you can use vSphere Auto Deploy cmdlets for testing compliance with the working rule set. The test verifies that hosts managed by a vCenter system are following the rules in the working rule set. By default, cmdlets

add the rule to the working rule set and activate the rules. Use the `NoActivate` parameter to add a rule only to the working rule set.

You use the following workflow with rules and rule sets.

1. Make changes to the working rule set.
2. Test the working rule set rules against a host to make sure that everything is working correctly.
3. Refine and retest the rules in the working rule set.
4. Activate the rules in the working rule set.
   If you add a rule in a VCF PowerCLI session and do not specify the `NoActivate` parameter, all rules that are currently in the working rule set are activated. You cannot activate individual rules.

See the VCF PowerCLI command-line help and How vSphere Auto Deploy Works with VCF PowerCLIfor more information on using vSphere Auto Deploy with VCF PowerCLI cmdlets. See Managing vSphere Auto Deploy with the vSphere Client for more information on using vSphere Auto Deploy with the vSphere Client.

Install and Configure vSphere Auto Deploy

Before you can start using vSphere Auto Deploy, you must prepare your environment in several steps.

You start with server setup and hardware preparation. You must configure the vSphere Auto Deploy service startup type in the vCenter system that you plan to use for managing the ESX hosts you provision, and install VCF PowerCLI.

- vSphere Auto Deploy Preinstallation Checklist
- Prepare Your System for vSphere Auto Deploy
- Using vSphere Auto Deploy Cmdlets

vSphere Auto Deploy Preinstallation Checklist

Before you can start the tasks in this vSphere Auto Deploy scenario, make sure that your environment meets the hardware and software requirements, and that you have the necessary permissions for the components included in the setup.

Table 20: Preinstallation Checklist

Required Software and Hardware	Details
vCenter	The vSphere Auto Deploy server is part of vCenter. You must enable and start the vSphere Auto Deploy service on the vCenter system. You can perform many of the setup tasks by logging in to vCenter. See Prepare Your System for vSphere Auto Deploy.
Storage	Storage for ESX datastores NFS, iSCSI, or Fibre Channel, with servers and storage arrays that are configured so the servers can detect the LUNs. • A list of target IP addresses for NFS or iSCSI. • A list of target volume information for NFS or iSCSI.
ESX hosts information	A list of target IP addresses for NFS or iSCSI. A list of target volume information for NFS or iSCSI. • Default route, net mask, and primary and secondary DNS server IP addresses. • IP address and net mask for the VMkernel primary management network. • IP address and net mask for other VMkernel networks such as storage, vSphere FT, or VMware vMotion. vSphere Auto Deploy does not overwrite existing partitions by default.
VCF PowerCLI	See *Install PowerCLI* topic in the *ESX Install* guide.
ESX software depot	The location of the ESX software depot on the Broadcom Support Portal. You use a URL to point to the image profile stored at that location, or you download a ZIP file to work with a local depot. Do not download the ESX image.
TFTP server	TFTP installer software such as WinAgents TFTP server.

Required Software and Hardware	Details
DHCP server	The DHCP server is included in the vSphere supported Windows Server versions.
DNS server	A working DNS server. You must add entries in both Forward (A Record) and Reverse (PTR Record) Zones for each target host.

You also need information about and administrator privileges to the core servers of the environment, including the Active Directory server, DNS server, DHCP server, NTP server, and so on.

You must have complete control of the broadcast domain of the subnet in which you deploy the setup. Ensure that no other DHCP, DNS, or TFTP server are on this subnet.

Prepare Your System for vSphere Auto Deploy

Before you can PXE boot an ESX host with vSphere Auto Deploy, you must install prerequisite software and set up the DHCP and TFTP servers that vSphere Auto Deploy interacts with.

- Verify that the hosts that you plan to provision with vSphere Auto Deploy meet the hardware requirements for ESX. See ESX Hardware Requirements.
- Verify that the ESX hosts have network connectivity to vCenter and that all port requirements are met. See the *vCenter Upgrade* guide.
- Verify that you have a TFTP server and a DHCP server in your environment to send files and assign network addresses to the ESX hosts that Auto Deploy provisions. See teh topics *Install the TFTP Server* and *Prepare the DHCP Server for vSphere Auto Deploy Provisioning* in the *ESX Installation* guide.
- Verify that the ESX hosts have network connectivity to DHCP, TFTP, and vSphere Auto Deploy servers.
- If you want to use VLANs in your vSphere Auto Deploy environment, you must set up the end to end networking properly. When the host is PXE booting, the firmware driver must be set up to tag the frames with proper VLAN IDs. You must do this set up manually by making the correct changes in the UEFI/BIOS interface. You must also correctly configure the ESX port groups with the correct VLAN IDs. Ask your network administrator how VLAN IDs are used in your environment.
- Verify that you have enough storage for the vSphere Auto Deploy repository. The vSphere Auto Deploy server uses the repository to store data it needs, including the rules and rule sets you create and the VIBs and image profiles that you specify in your rules.

  Best practice for ESX 9.0 and later is to allocate 6 GB to have enough room for four image profiles and some extra space. Each image profile requires approximately 400 MB. Determine how much space to reserve for the vSphere Auto Deploy repository by considering how many image profiles you expect to use.
- Obtain administrative privileges to the DHCP server that manages the network segment you want to boot from. You can use a DHCP server already in your environment, or install a DHCP server. For your vSphere Auto Deploy setup, replace the `gpxelinux.0` filename with `snponly64.efi.vmw-hardwired` for UEFI or `undionly.kpxe.vmw-hardwired` for BIOS. For more information on DHCP configurations, see Sample DHCP Configurations.
- Secure your network as for any other PXE-based deployment method. vSphere Auto Deploy transfers data over SSL to prevent casual interference and snooping. However, the authenticity of the client or the vSphere Auto Deploy server is not checked during a PXE boot.
- If you want to manage vSphere Auto Deploy with VCF PowerCLI cmdlets, verify that PowerShell 7.5 is installed. See the *vSphere PowerCLI User's Guide*.
- Set up a remote syslog server. See the *vCenter and Host Management* documentation for syslog server configuration information. Configure the first host you boot to use the remote syslog server and apply that host's host profile to all other target hosts. Optionally, install and use VMware Cloud Foundation Operations for logs, which provides log aggregation and analytics for VMware and non-VMware products, virtual and physical, with near real-time search and analytics of log events.
- Install ESX Dump Collector, set up your first host so that all core dumps are directed to ESX Dump Collector, and apply the host profile from that host to all other hosts. See Configure ESX Dump Collector with ESXCLI.

- If the hosts that you plan to provision with vSphere Auto Deploy are with legacy BIOS, verify that the vSphere Auto Deploy server has an IPv4 address. PXE booting with legacy BIOS firmware is possible only over IPv4. PXE booting with UEFI firmware is possible with either IPv4 or IPv6.

If you want to manage vSphere Auto Deploy with VCF PowerCLI cmdlets, see *Set Up vSphere Auto Deploy and Provision Hosts with vSphere PowerCLI*.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. Click **Enable Auto Deploy and Image Builder** to activate the service.

   If the **Image Builder** service is already active, select the **Configure** tab and click **Enable Auto Deploy Service**.

   The **Software Depot** page appears.
3. Configure the TFTP server.
   a) Click the **Configure** tab.
   b) Click **Download TFTP Boot Zip** to download the TFTP configuration file and unzip the file to the directory in which your TFTP server stores files.
   c) Optional: To use a proxy server, click **Add** on the *Auto Deploy Runtime Summary* pane and enter a proxy server URL in the text box.

      Using reverse proxy servers can offload the requests made to the vSphere Auto Deploy server.
4. Set up your DHCP server to point to the TFTP server on which the TFTP ZIP file is located.
   a) Specify the TFTP Server's IP address in DHCP option 66, frequently called next-server.
   b) Specify the boot filename, which is `snponly64.efi.vmw-hardwired` for UEFI or `undionly.kpxe.vmw-hardwired` for BIOS in the DHCP option 67, frequently called `boot-filename`.
5. Set each host you want to provision with vSphere Auto Deploy to network boot or PXE boot, following the manufacturer's instructions.
6. Optional: If you set up your environment to use Thumbprint mode, you can use your own Certificate Authority (CA) by replacing the OpenSSL certificate `rbd-ca.crt` and the OpenSSL private key `rbd-ca.key` with your own certificate and key file.

   The files are in `/etc/vmware-rbd/ssl/`.

   By default, vCenter uses VMware Certificate Authority (VMCA).

When you start an ESX host that is set up for vSphere Auto Deploy, the host contacts the DHCP server and is directed to the vSphere Auto Deploy server, which provisions the host with the image profile specified in the active rule set.

- You can change the default configuration properties of the **Auto Deploy Service**. For more information, see "Configuring vCenter" in the *vCenter and Host Management* documentation.
- You can change the default configuration properties of the **Image Builder Service**. For more information, see "Configuring vCenter" in the *vCenter and Host Management* documentation.
- Define a rule that assigns an image profile and optional host profile, host location, or script bundle to the host. For managing vSphere Auto Deploy with VCF PowerCLI cmdlets, see the How vSphere Auto Deploy Works with VCF PowerCLI section. For managing vSphere Auto Deploy with the vSphere Client, see the Managing vSphere Auto Deploy with the vSphere Client section.
- Configure the first host that you provision as a reference host. Use the storage, networking, and other settings you want for your target hosts to share. Create a host profile for the reference host and write a rule that assigns both the already tested image profile and the host profile to target hosts.
- If you want to have vSphere Auto Deploy overwrite existing partitions, set up a reference host to do auto partitioning and apply the host profile of the reference host to other hosts. See Configure a Reference Host for Auto-Partitioning .
- If you have to configure host-specific information, set up the host profile of the reference host to prompt for user input. For more information about host customizations, see the *vSphere Host Profiles* documentation.

Using vSphere Auto Deploy Cmdlets

vSphere Auto Deploy cmdlets are implemented as Microsoft PowerShell cmdlets and included in VCF PowerCLI. Users of vSphere Auto Deploy cmdlets can take advantage of all VCF PowerCLI features.

Experienced PowerShell users can use vSphere Auto Deploy cmdlets just like other PowerShell cmdlets. If you are new to PowerShell and VCF PowerCLI, the following tips might be helpful.

You can type cmdlets, parameters, and parameter values in the VCF PowerCLI shell.

- Get help for any cmdlet by running `Get-Help`*`cmdlet_name`*.
- Remember that PowerShell is not case sensitive.
- Use tab completion for cmdlet names and parameter names.
- Format any variable and cmdlet output by using `Format-List` or `Format-Table`, or their short forms `fl` or `ft`. For more information, run the `Get-Help Format-List` cmdlet.

Passing Parameters by Name

You can pass in parameters by name in most cases and surround parameter values that contain spaces or special characters with double quotes.

```
Copy-DeployRule -DeployRule testrule -ReplaceItem MyNewProfile
```

Most examples in the *vCenter Deployment and Setup* documentation pass in parameters by name.

Passing Parameters as Objects

You can pass parameters as objects if you want to perform scripting and automation. Passing in parameters as objects is useful with cmdlets that return multiple objects and with cmdlets that return a single object. Consider the following example.

1. Bind the object that encapsulates rule set compliance information for a host to a variable.
   ```
   $tr = Test-DeployRuleSetCompliance MyEsx42
   ```
2. View the `itemlist` property of the object to see the difference between what is in the rule set and what the host is currently using.
   ```
   $tr.itemlist
   ```
3. Remediate the host to use the revised rule set by using the `Repair-DeployRuleSetCompliance` cmdlet with the variable.
   ```
   Repair-DeployRuleSetCompliance $tr
   ```

The example remediates the host the next time you boot the host.

How vSphere Auto Deploy Works with VCF PowerCLI

You can manage vSphere Auto Deploy with VCF PowerCLI cmdlets to create rules that associate ESX hosts with various objects on the vCenter target.

You can manage vSphere Auto Deploy with VCF PowerCLI cmdlets to create rules that associate hosts with image profiles, host profiles, custom scripts and locations on the vCenter target. You can also update hosts by testing rule compliance and repairing compliance issues.

- Overview of the vSphere Auto Deploy Process by Using VCF PowerCLI
- Inventory of vSphere Auto Deploy VCF PowerCLI Cmdlets
- Assign an Image Profile to Hosts
- Write a Rule and Assign a Host Profile to Hosts
- Write a Rule and Assign a Host to a Folder or Cluster
- Configure a Stateless System by Running a Custom Script
- Test and Repair Rule Compliance
- Register a Caching Proxy Server Address with vSphere Auto Deploy

Overview of the vSphere Auto Deploy Process by Using VCF PowerCLI

You can write VCF PowerCLI scripts that provision hosts and boot hosts with an image that you specify, customizing the image profile, host profile, or vCenter location.

You can manage vSphere Auto Deploy with VCF PowerCLI cmdlets to create rules that associate hosts with image profiles, host profiles, custom scripts and locations on the vCenter target. You can also update hosts by testing rule compliance and repairing compliance issues.

Getting started with vSphere Auto Deploy requires that you learn how vSphere Auto Deploy works, install the vSphere Auto Deploy server, install VCF PowerCLI, write VCF PowerCLI rules that provision hosts, and power on your hosts to be booted with the image profile you specify. You can customize of the image profile, host profile, and vCenter location.

See vSphere PowerCLI Scenario for vSphere Auto Deploy for a step-by-step exercise that helps you set up your first vSphere Auto Deploy environment.

To provision the hosts in your environment with vSphere Auto Deploy successfully, you can follow these steps.

1. Deploy vCenter.
   The vSphere Auto Deploy server is included.
2. Configure the vSphere Auto Deploy service startup type.
   See Prepare Your System for vSphere Auto Deploy.
3. Install VCF PowerCLI, which includes vSphere Auto Deploy and vSphere ESX Image Builder cmdlets.
   See Configure vSphere ESX Image Builder, Using vSphere Auto Deploy Cmdlets, and Using VMware.ImageBuilder Cmdlets.
4. Find the image profile that includes the VIBs that you want to deploy to your hosts.
   - Usually, you add the depots containing the required software to your VCF PowerCLI session, and then select an image profile from one of those depots.
   - To create a custom image profile, use vSphere ESX Image Builder cmdlets to clone an existing image profile and add the custom VIBs to the clone.

   You must use vSphere ESX Image Builder for customization only if you have to add or remove VIBs. In most cases, you can add the depot where VMware hosts the image profiles to your VCF PowerCLI session as a URL.
5. Start a PowerShell session and connect to the vCenter system.
6. Use the `New-DeployRule`VCF PowerCLI cmdlet to write a rule that assigns the image profile to one host, to multiple hosts specified by a pattern, or to all hosts.
   ```
   New-DeployRule -Name "testrule" -Item image-profile -AllHosts
   ```
   See Assign an Image Profile to Hosts.

   Important:

   With ESX 9.0, support for stateless installation is deprecated. To continue using stateless hosts, you must use the `Set-ClusterNetworkBootMode` cmdlet that allows you to use network booting and provision stateless hosts in a selected cluster managed by vSphere Lifecycle Manager images.

   Note:
   vSphere Auto Deploy is optimized for provisioning hosts that have a fixed MAC address to IP address mapping in DHCP (sometimes called DHCP reservations). If you want to use static IP addresses, you must set up the host profile to prompt for host customization. For more information, see the *vSphere Host Profiles* documentation.
7. Power on the hosts that you want to provision.
8. If you do not use a vSphere Lifecycle Manager image or a vSphere Configuration Profile, set up a host you provision as a reference host for a host profile.
   You can specify the reference host syslog settings, firewall settings, storage, networking, and so on.
9. Set up the host you provisioned as a reference host for your host profile.
   You can specify the reference host syslog settings, firewall settings, storage, networking, and so on. See Setting Up a vSphere Auto Deploy Reference Host.
10. Create and export a host profile for the reference host.
    See the *Host Profiles* documentation.
11. To provision multiple hosts with the host profile, use the `Copy-DeployRule` cmdlet to edit the previously created rule.

You can revise the rule to assign not only an image profile but also a host profile, a vCenter location, and a custom script bundle.

```
Copy-DeployRule -DeployRule "testrule" -ReplaceItem my_host_profile_from_reference_host,my_target_cluster
                -ReplacePattern  "ipv4=192.XXX.1.10-192.XXX.1.20"
```

Where *my_host_profile_from_reference_host* is the name of the reference host profile, and *my_target_cluster* is the name of the target cluster.

12. Perform the test and repair compliance operations to remediate the hosts.
    See Test and Repair Rule Compliance .
13. Verify that the hosts you provisioned meet the following requirements.
    - Each host is connected to the vCenter system.
    - The hosts are not in maintenance mode.
    - The hosts have no compliance failures.
    - Each host with a host profile that requires user input has up-to-date host customization information.

    Remediate host associations and compliance problems and reboot hosts until all hosts meet the requirements.

Read *Understanding vSphere Auto Deploy* for an introduction to the boot process, differences between first and subsequent boots, and an overview of using host customization.

Inventory of vSphere Auto Deploy VCF PowerCLI Cmdlets

You specify the rules that assign image profiles and host profiles to hosts using a set of VCF PowerCLI cmdlets that are included in VCF PowerCLI.

If you are new to VCF PowerCLI, read the VCF PowerCLI documentation and review Using vSphere Auto Deploy Cmdlets. You can get help for any command at the PowerShell prompt.

- Basic help: `Get-Helpcmdlet_name`
- Detailed help: `Get-Help cmdlet_name-Detailed`

Note:
When you run vSphere Auto Deploy cmdlets, provide all parameters on the command line when you invoke the cmdlet. Supplying parameters in interactive mode is not recommended.

Important:

Starting with ESX 9.0, you cannot use the `New-DeployRule` cmdlet for images earlier than ESX 8.0.

Table 21: Rule Engine VCF PowerCLI Cmdlets

Command	Description
`Get-DeployCommand`	Returns a list of vSphere Auto Deploy cmdlets.
`Set-ClusterNetworkBootMode`	Configures the network boot options for ESX hosts in clusters managed by vSphere Lifecycle Manager images. When used with the `stateless` parameter, the cmdlet allows the use of UEFI PXE and UEFI HTTP(S) network booting to provision stateless hosts in a selected cluster. Equals the **Enable Auto Deploy Stateless** option in the vSphere Client. When used with the `bootstrap` parameter, the cmdlet allows the use of UEFI HTTP(S) network booting to provision stateful hosts in a selected cluster. Equals the **Enable Zero Touch Provisioning** option in the vSphere Client.
`Reset-ClusterNetworkBootMode`	Restores the default stateful provisioning of hosts in a cluster from the network boot mode.
`New-DeployRule`	Creates a new rule with the specified items and patterns.
`Set-DeployRule`	Updates an existing rule with the specified items and patterns. You cannot update a rule that is part of a rule set.
`Get-DeployRule`	Retrieves the rules with the specified names.

Command	Description
`Copy-DeployRule`	Clones and updates an existing rule.
`Add-DeployRule`	Adds one or more rules to the working rule set and, by default, also to the active rule set. Use the `NoActivate` parameter to add a rule only to the working rule set.
`Remove-DeployRule`	Removes one or more rules from the working rule set and from the active rule set. Run this command with the `-Delete` parameter to completely delete the rule.
`Set-DeployRuleset`	Explicitly sets the list of rules in the working rule set.
`Get-DeployRuleset`	Retrieves the current working rule set or the current active rule set.
`Switch-ActiveDeployRuleset`	Activates a rule set so that any new requests are evaluated through the rule set.
`Get-VMHostMatchingRules`	Retrieves rules matching a pattern. For example, you can retrieve all rules that apply to a host or hosts. Use this cmdlet primarily for debugging.
`Test-DeployRulesetCompliance`	Checks whether the items associated with a specified host are in compliance with the active rule set.
`Repair-DeployRulesetCompliance`	Given the output of `Test-DeployRulesetCompliance`, this cmdlet updates the image profile, host profile, and location for each host in the vCenter inventory. The cmdlet might apply image profiles, apply host profiles, or move hosts to prespecified folders or clusters on the vCenter system.
`Apply-EsxImageProfile`	Associates the specified image profile with the specified host.
`Get-VMHostImageProfile`	Retrieves the image profile in use by a specified host. This cmdlet differs from the `Get-EsxImageProfile` cmdlet in vSphere mage Builder.
`Repair-DeployImageCache`	Use this cmdlet only if the vSphere Auto Deploy image cache is accidentally deleted.
`Get-VMHostAttributes`	Retrieves the attributes for a host that are used when the vSphere Auto Deploy server evaluates the rules.
`Get-DeployMachineIdentity`	Returns a string value that vSphere Auto Deploy uses to logically link an ESX host in vCenter to a physical machine.
`Set-DeployMachineIdentity`	Logically links a host object in the vCenter database to a physical machine. Use this cmdlet to add hosts without specifying rules.
`Get-DeployOption`	Retrieves the vSphere Auto Deploy global configuration options. This cmdlet currently supports the vlan-id option, which specifies the default VLAN ID for the ESX Management Network of a host provisioned with vSphere Auto Deploy. vSphere Auto Deploy uses the value only if the host boots without a host profile.
`Set-DeployOption`	Sets the value of a global configuration option. Currently supports the vlan-id option for setting the default VLAN ID for the ESX Management Network.
`Add-ProxyServer`	Adds a proxy server to the vSphere Auto Deploy database. Run the command with the `-Address` parameter to specify the IPv4 or IPv6 address. The address can include a port number.
`List-ProxyServer`	Lists the proxy servers that are currently registered with vSphere Auto Deploy.
`Delete-ProxyServer`	Deletes one or more proxy servers from the list of proxy servers that are registered with vSphere Auto Deploy. You can run the command with the `-id` parameter from the list of proxy servers or with the`-Address` parameter by specifying the IPv4 or IPv6 address of the proxy server you want to delete.
`Add-ScriptBundle`	Adds one or more script bundles to the vSphere Auto Deploy server.
`Get-ScriptBundle`	Retrieves the list of script bundles available on the vSphere Auto Deploy server and the scripts they contain.
`Remove-ScriptBundle`	Removes a script bundle from vSphere Auto Deploy. Applicable for vSphere version 6.7 and later.

Command	Description
`Get-CustomCertificates`	Retrieves the custom host certificate uploaded into AutoDeploy. You must run the command with the `-HostId [MAC_Address | BIOS_UUID]` parameter. The first time you add custom certificates, you don't see any certificates returned by this cmdlet.
`List-CustomCertificates`	Retrieves information about all custom host certificates used by Auto Deploy. The list provides details for the name of the certificate, `Host ID`, and `Associated Host Name`, which reflects the name of the vCenter for the Auto Deploy server.
`Add-CustomCertificate`	Adds a custom certificate to the VMware Endpoint Certificate Store and associates it with an ESX host. The certificate becomes active upon host reboot. You can use the `Get-CustomCertificate` cmdlet to retrieve the custom host certificate key. You can run the command with the `-HostId [MAC_Address | BIOS_UUID]` parameter to associate the certificate to the host, specifying a `-Key [file:///path/to/key.key]` and `-Cert [file:///path/to/cert.crt]`. Using this cmdlet requires the **AutoDeploy.Rule.Create** privilege on the root folder of vCenter.
`Remove-CustomCertificates`	Removes a set of custom host certificates from Auto Deploy. The certificate entries are deleted from the database and the certificate files are removed from the filestore. Hosts that have already booted with a custom certificate must be rebooted to receive a new certificate. You must provide at least one of `-Cert` or `-HostId` parameters. Using this cmdlet requires the **AutoDeploy.Rule.Create** privilege on the root folder of vCenter.

Assign an Image Profile to Hosts

Before you can provision a host, you must create rules that assign an image profile to each host that you want to provision by using vSphere Auto Deploy.

vSphere Auto Deploy extensibility rules enforce that VIBs at the CommunitySupported level can only contain files from certain predefined locations, such as the ESXCLI plug-in path, jumpstart plug-in path, and so on. If you add a VIB that is in a different location to an image profile, a warning results. You can override the warning by using the `force` option.

If you call the `New-DeployRule` cmdlet on an image profile that includes VIBs at the CommunitySupported level which violate the rule, set `$DeployNoSignatureCheck = $true` before adding the image profile. With that setting, the system ignores signature validation and does not perform the extensibility rules check.

> **Note:**
> Image profiles that include VIBs at the CommunitySupported level are not supported on production systems.

1. In a VCF PowerCLI session, run the `Connect-VIServer` cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_or_ipv6_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate warnings result. In a development environment, you can ignore the warning.

2. Determine the location of a public software depot, or define a custom image profile by using vSphere ESX Image Builder.

3. Run `Add-EsxSoftwareDepot` to add the software depot that contains the image profile to the VCF PowerCLI session.

Depot Type	Cmdlet
Remote depot	Run `Add-EsxSoftwareDepot` *depot_url*.
ZIP file	1. Download the ZIP file to a local file path. 2. Run `Add-EsxSoftwareDepot C:\`*file_path*`\`*my_offline_depot*`.zip`.

4. In the depot, find the image profile that you want to use by running the `Get-EsxImageProfile` cmdlet.

   By default, the ESX depot includes one base image profile that includes VMware Tools and has the string `standard` in its name, and one base image profile that does not include VMware Tools.

5. Define a rule in which hosts with certain attributes, for example a range of IP addresses, are assigned to the image profile.

   ```
   New-DeployRule -Name "testrule" -Item "My Profile25" -
   Pattern "vendor=Acme,Zven", "ipv4=192.XXX.1.10-192.XXX.1.20"
   ```

   Double quotes are required if a name contains spaces, optional otherwise. Specify `-AllHosts` instead of a pattern to apply the item to all hosts.

   The cmdlet creates a rule named `testrule`. The rule assigns the image profile named My Profile25 to all hosts with a vendor of Acme or Zven that also have an IP address in the specified range.

6. Add the rule to the rule set.

   ```
   Add-DeployRule testrule
   ```

   By default, the rule is added to both the working rule set and the active rule set. If you use the `NoActivate` parameter, the working rule set does not become the active rule set.

When the host boots from iPXE, it reports attributes of the machine to the console. Use the same format of the attributes when writing deploy rules.

```
**********************************************************************
* Booting through VMware AutoDeploy...
*
* Machine attributes:
* . asset=No Asset Tag
* . domain=vmware.com
* . hostname=myhost.mycompany.com
* . ipv4=XX.XX.XXX.XXX
* . mac=XX:Xa:Xb:Xc:Xx:XX
* . model=MyVendorModel
* . oemstring=Product ID: XXXXXX-XXX
* . serial=XX XX XX XX XX XX...
* . uuid=XXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXX
* . vendor=MyVendor
**********************************************************************
```

- For hosts already provisioned with vSphere Auto Deploy, perform the compliance testing and repair operations to provision them with the new image profile. See Test and Repair Rule Compliance .
- Turn on unprovisioned hosts to provision them with the new image profile.

Write a Rule and Assign a Host Profile to Hosts

vSphere Auto Deploy can assign a host profile to one or more ESX hosts.

The host profile might include information about storage configuration, network configuration, or other characteristics of the host. If you add a host to a cluster, that cluster's host profile is used.

- Install PowerCLI and all prerequisite software.
- Export the host profile that you want to use.

In many cases, you assign a host to a cluster instead of specifying a host profile explicitly. The host uses the host profile of the cluster.

1. In a VCF PowerCLI session, run the `Connect-VIServer` cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_or_ipv6_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate warnings result. In a development environment, you can ignore the warning.

2. Using the vSphere Client, set up a host with the settings you want to use and create a host profile from that host.
3. Find the name of the host profile by running `Get-VMhostProfile` VCF PowerCLI cmdlet, passing in the ESX host from which you create a host profile.
4. At the VCF PowerCLI prompt, define a rule in which host profiles are assigned to hosts with certain attributes, for example a range of IP addresses.

   ```
   New-DeployRule -Name "testrule2" -Item my_host_profile -Pattern "vendor=Acme,Zven",
    "ipv4=192.XXX.1.10-192.XXX.1.20"
   ```

   The specified item is assigned to all hosts with the specified attributes. This example specifies a rule named **testrule2**. The rule assigns the specified host profile *my_host_profile* to all hosts with an IP address inside the specified range and with a manufacturer of Acme or Zven.
5. Add the rule to the rule set.

   ```
   Add-DeployRule testrule2
   ```

   By default, the working rule set becomes the active rule set, and any changes to the rule set become active when you add a rule. If you use the `NoActivate` parameter, the working rule set does not become the active rule set.

- Assign a host already provisioned with vSphere Auto Deploy to the new host profile by performing compliance test and repair operations on those hosts. For more information, see Test and Repair Rule Compliance .
- Power on unprovisioned hosts to provision them with the host profile.

Write a Rule and Assign a Host to a Folder or Cluster

vSphere Auto Deploy can assign a host to a folder or cluster. When the host boots, vSphere Auto Deploy adds it to the specified location on the vCenter. Hosts assigned to a cluster inherit the cluster's host profile.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.
- Verify that the folder you select is in a data center or in a cluster. You cannot assign the host to a standalone top-level folder.

1. In a VCF PowerCLI session, run the `Connect-VIServer` cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_or_ipv6_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate warnings result. In a development environment, you can ignore the warning.
2. Define a rule in which hosts with certain attributes, for example a range of IP addresses, are assigned to a folder or a cluster.

   ```
   New-DeployRule -Name testrule3 -Item "my folder"-Pattern "vendor=Acme,Zven",
    "ipv4=192.XXX.1.10-192.XXX.1.20"
   ```

   This example passes in the folder by name. You can instead pass in a folder, cluster, or data center object that you retrieve with the `Get-Folder`, `Get-Cluster`, or `Get-Datacenter` cmdlet.
3. Add the rule to the rule set.

   ```
   Add-DeployRule testrule3
   ```

   By default, the working rule set becomes the active rule set, and any changes to the rule set become active when you add a rule. If you use the `NoActivate` parameter, the working rule set does not become the active rule set.

- Assign a host already provisioned with vSphere Auto Deploy to the new folder or cluster location by performing test and repair compliance operation. See Test and Repair Rule Compliance .
- Power on unprovisioned hosts to add them to the specified vCenter location.

Configure a Stateless System by Running a Custom Script

You can use vSphere Auto Deploy to configure one or more hosts by associating custom scripts with a vSphere Auto Deploy rule.

- Verify that the script bundle you want to associate with a vSphere Auto Deploy rule is in `.tgz` format, with a maximum size of 10 MB, and written in Python or BusyBox ash scripting language.

The scripts run in alphabetical order after the initial ESX boot workflow of the host.

1. In a VCF PowerCLI session, run the `Connect-VIServer` cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_or_ipv6_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate warnings result. In a development environment, you can ignore the warning.

2. Run the `Add-ScriptBundle` cmdlet to add the script bundle that contains the necessary scripts to the vSphere Auto Deploy inventory.

   ```
   Add-ScriptBundle c:/temp/MyScriptBundle.tgz
   ```

   The name of the script bundle without the `.tgz` extension is the name identifier or object of the script bundle item. You can update an existing script bundle by using the `-Update` parameter with the `Add-ScriptBundle` cmdlet.

3. Optional: Run the `Get-ScriptBundle` cmdlet to verify that the script bundle is added to the vSphere Auto Deploy inventory.

4. Define a rule in which hosts with certain attributes, for example a range of IP addresses, are assigned to the script bundle.

   ```
   New-DeployRule -Name "testrule4" -Item "MyScriptBundle" -
   Pattern "vendor=Acme,Zven", "ipv4=192.XXX.1.10-192.XXX.1.20"
   ```

   Double quotes are required if a name contains spaces, optional otherwise. Specify `-AllHosts` instead of a pattern to apply the item to all hosts.

   You create a rule named *testrule4*. The rule assigns the script bundle named My Script Bundle to all hosts with a vendor of Acme or Zven that also have an IP address in the specified range. You can use the name identifier of the script bundle or the object returned by the `Get-ScriptBundle` cmdlet to identify the script bundle you want to associate with the rule.

5. Add the rule to the rule set.

   ```
   Add-DeployRule testrule4
   ```

   By default, the rule is added to both the working rule set and the active rule set. If you use the `NoActivate` parameter, the working rule set does not become the active rule set.

- For hosts already provisioned with vSphere Auto Deploy, perform the compliance testing and repair operations to provision them with the new scripts. See Test and Repair Rule Compliance .
- Turn on unprovisioned hosts to provision them with the new scripts.

Test and Repair Rule Compliance

Test new or modified rules for compliance and repair accordingly, as changes in the vSphere Auto Deploy rule set are not updated automatically.

When you add a rule to the vSphere Auto Deploy rule set or modify one or more rules, hosts are not updated automatically. vSphere Auto Deploy applies the new rules only when you test their rule compliance and perform remediation.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.
- Verify that your infrastructure includes one or more ESX hosts provisioned with vSphere Auto Deploy, and that the host on which you installed VCF PowerCLI can access those ESX hosts.

1. In a VCF PowerCLI session, run the `Connect-VIServer` cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_or_ipv6_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate warnings result. In a development environment, you can ignore the warning.

2. Use VCF PowerCLI to check which vSphere Auto Deploy rules are currently available.

   ```
   Get-DeployRule
   ```

   The system returns the rules and the associated items and patterns.

3. Modify one of the available rules.

   For example, you can change the image profile and the name of the rule.

   ```
   Copy-DeployRule -DeployRule testrule -ReplaceItem MyNewProfile
   ```

   You cannot edit a rule already added to the active rule set. Instead, you can copy the rule and replace the item or pattern you want to change.

4. Verify that you can access the host for which you want to test rule set compliance.

   ```
   Get-VMHost -Name MyEsxi42
   ```

5. Run the cmdlet that tests rule set compliance for the host, and bind the return value to a variable for later use.

   ```
   $tr = Test-DeployRuleSetCompliance MyEsxi42
   ```

6. Examine the differences between the contents of the rule set and configuration of the host.

   ```
   $tr.itemlist
   ```

   If the host for which you want to test the new rule set compliance is compliant with the active rule set, the system returns a table of current and expected items.

   ```
   CurrentItem                              ExpectedItem
   -----------                              ------------
   My Profile 25MyNewProfile
   ```

7. Remediate the host to use the revised rule set the next time you boot the host.

   ```
   Repair-DeployRuleSetCompliance $tr
   ```

If the rule you changed specified the inventory location, the change takes effect when you repair compliance. For all other changes, reboot your host to have vSphere Auto Deploy apply the new rule and to achieve compliance between the rule set and the host.

Register a Caching Proxy Server Address with vSphere Auto Deploy

Simultaneously booting large number of stateless hosts places a significant load on the vSphere Auto Deploy server. You can load balance the requests between the vSphere Auto Deploy server and one or more proxy servers that you register with vSphere Auto Deploy.

See Prepare Your System for vSphere Auto Deploy.

1. In a VCF PowerCLI session, run the `Connect-VIServer` cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_or_ipv6_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate warnings result. In a development environment, you can ignore the warning.

2. Register a caching proxy server addresses with vSphere Auto Deploy by running the `Add-ProxyServer` cmdlet.

   ```
   Add-ProxyServer -Address 'https://proxy_server_ip_address:port_number'
   ```

   You can run the cmdlet multiple times to register multiple proxy servers. The address can contain a port number.

3. Optional: Run the `List-ProxyServer` cmdlet to verify that the caching proxy server is registered with vSphere Auto Deploy.

vSphere Auto Deploy Tasks by Using the vSphere Client

- Managing vSphere Auto Deploy with the vSphere Client

- Overview of the vSphere Auto Deploy Process by Using the vSphere Client
- Create a Deploy Rule
- Clone a Deploy Rule
- Edit a Deploy Rule
- Activate, Deactivate, and Reorder Deploy Rules
- View Host Associations
- Edit the Image Profile Association of a Host
- Remediate a Non-compliant Host
- Add a Host to the vSphere Auto Deploy Inventory
- Add a Host to a Cluster That Uses a Single Image
- Add a Host to a Cluster Managed by vSphere Configuration Profiles
- Working with Script Bundles
- Download vSphere Auto Deploy Logs
- Start, Stop, or Restart the vSphere Auto Deploy Service

Managing vSphere Auto Deploy with the vSphere Client

You can add ESX hosts to the vSphere Auto Deploy inventory, create, monitor, and manage rules, and host associations by using the vSphere Client.

- Managing vSphere Auto Deploy with the vSphere Client
- Overview of the vSphere Auto Deploy Process by Using the vSphere Client
- Create a Deploy Rule
- Clone a Deploy Rule
- Edit a Deploy Rule
- Activate, Deactivate, and Reorder Deploy Rules
- View Host Associations
- Edit the Image Profile Association of a Host
- Remediate a Non-compliant Host
- Add a Host to the vSphere Auto Deploy Inventory
- Add a Host to a Cluster That Uses a Single Image
- Add a Host to a Cluster Managed by vSphere Configuration Profiles
- Working with Script Bundles
- Download vSphere Auto Deploy Logs
- Start, Stop, or Restart the vSphere Auto Deploy Service

Overview of the vSphere Auto Deploy Process by Using the vSphere Client

In the vSphere Client, similar to VCF PowerCLI, you can create deploy rules that provision hosts and boot hosts with an image that you specify.

Getting started with vSphere Auto Deploy requires that you learn how vSphere Auto Deploy works, start the vSphere Auto Deploy and vSphere ESX Image Builder vCenter services, create deploy rules that provision hosts, and power on your hosts to be booted with the image or profile you specify.

> **Important:**
>
> The vSphere Host Profiles capability is deprecated in ESX 9.0 and will be removed in a future release.

The workflow for provisioning the hosts in your environment with vSphere Auto Deploy includes the following tasks:

1. Deploy vCenter.
   The vSphere Auto Deploy server is included.
2. Configure the vSphere Auto Deploy and vSphere ESX Image Builder service startup types.
   See Prepare Your System for vSphere Auto Deploy and Configure the vSphere ESX Image Builder.
3. Add or import a software depot to the vSphere Auto Deploy inventory.

See Add a Software Depot or Import a Software Depot.

4. (Optional) If you want to create a custom image profile, clone, or create an image profile by using the vSphere Client.
   See Clone an Image Profile or Create an Image Profile.

   Important:

   With ESX 9.0, support for stateless installation is deprecated. To continue using stateless ESX hosts, you must either have an empty cluster or create a new one in the vSphere Lifecycle Manager, and activate stateless support on that cluster in the Auto Deploy interface in the vSphere Client.

   In the vSphere Client, under **Auto Deploy > Clusters** you see a button **Activate Stateless Support**.

   You manage the lifecycle of hosts part of stateless clusters or standalone hosts only by using Auto Deploy. vSphere Lifecycle Manager operations relevant for stateful hosts such as single image association, image compliance, and remediation, are not supported for stateless clusters.
5. Create a deploy rule that assigns a host location or an image profile to one host, to multiple hosts specified by a pattern, or to all hosts.
   See Create a Deploy Rule.

   Note:
   vSphere Auto Deploy is optimized for provisioning hosts that have a fixed MAC address to IP address mapping in DHCP (sometimes called DHCP reservations). If you want to use static IP addresses, you must set up the host profile to prompt for host customization. For more information, see the *vSphere Host Profiles* documentation.
6. Power on the hosts that you want to provision.
7. If you do not use a vSphere Lifecycle Manager image or a vSphere Configuration Profile, set up a host you provision as a reference host for a host profile.
   You can specify the reference host syslog settings, firewall settings, storage, networking, and so on.
8. Extract a host profile from the reference host or use a specific location, such as a cluster managed by a vSphere Lifecycle Manager image or by a vSphere Configuration Profile.
9. To provision multiple hosts with the host profile, clone or edit the previously created rule by using the vSphere Client.
   See Clone a Deploy Rule or Edit a Deploy Rule.
10. Activate the new rule and deactivate the old one.
    See Activate, Deactivate, and Reorder Deploy Rules.
11. Remediate the host associations to apply the new rule to the host.
    See Remediate a Non-compliant Host.
12. Verify that the hosts you provisioned meet the following requirements.
    - Each host is connected to the vCenter system.
    - The hosts are not in maintenance mode.
    - The hosts have no compliance failures.
    - Each host with a host profile that requires user input has up-to-date host customization information.

    Remediate host associations and compliance problems and reboot hosts until all hosts meet the requirements.

Create a Deploy Rule

Before you provision ESX hosts with vSphere Auto Deploy, you must create rules that assign host locations, image and host profiles to the hosts.

Important:

With ESX 9.0, support for stateless installs is deprecated. To continue using stateless ESX hosts, you must either have an empty cluster or create a new one in the vSphere Lifecycle Manager, and activate stateless support on that cluster in the Auto Deploy interface in the vSphere Client.

You cannot switch an existing cluster from stateful to stateless cluster or the other way around.

You cannot switch a cluster with attached stateful host profile from stateful to stateless.

An ESX host can match more than one vSphere Auto Deploy rule criteria, when this is the case, the rule order is considered.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.
- If you want to include an image profile to the rule, verify that the software depot you need is added to the inventory. See *Add a Software Depot* or *Import a Software Depot*.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deploy Rules** tab, click **New Deploy Rule**.
   The **New Deploy Rule** wizard appears.
3. On the **Name and hosts** page of the wizard, enter a name for the new rule.
4. Select to either apply the rule to all hosts in the inventory or only to hosts that match a specific pattern.
   You can select one or more patterns.
   For example, the rule can apply only to hosts in a vCenter Single Sign-On domain, with a specific host name, or that match a specific IPv4 range.
5. On the **Configuration** page of the wizard, you can optionally include items in the rule.
   Each enabled item adds a new page to the wizard.

Option	Action
Host Location	Add the hosts that match the criteria of the rule to a specific location, such as a cluster managed by a vSphere Lifecycle Manager image or by a vSphere Configuration Profile.
Image	Assign an image profile to the hosts that match the rule criteria.
Host Settings	Assign a host profile to the hosts that match the rule criteria.
Script Bundle	Assign a script bundle to the host that match the rule criteria.

6. Optional: On the **Select host location** page of the wizard, select a data center, folder, or cluster as host location for the hosts that match the rule. With ESX 9.0, support for stateless installs is deprecated and along with host location, you must define the type of hosts that the rule deploys. Select the Stateless (Network boot) option under **Applicability** if you want to create stateless hosts.
7. Optional: On the **Select Image** page of the wizard, use the drop-down menu to select a software depot and choose an image profile from the list.
   If you want to bypass the acceptance level verification for the image profile, select the **Skip image profile signature check** check box.
8. Optional: On the **Select host settings** page of the wizard, select a host profile from the list.
9. Optional: On the **Select script bundle** page of the wizard, select a script bundle from the list.
10. On the **Ready to complete** page, review the summary information for the new rule.

You can view the newly created rule listed on the **Deploy Rules** tab.

- Activate a vSphere Auto Deploy rule. See *Activate, Deactivate, and Reorder Deploy Rules*.
- Edit a vSphere Auto Deploy rule. See *Edit a Deploy Rule*.
- Clone a vSphere Auto Deploy rule. See *Clone a Deploy Rule*.
- View the host location, image profile, host profile, and added script bundles. See *View Host Associations*.
- Remediate non-compliant hosts. See *Remediate a Non-compliant Host*.
- Change the image profile association of a host. See *Edit the Image Profile Association of a Host*.

Clone a Deploy Rule

You can use a vSphere Auto Deploy rule as a template and modify only parts of the rule instead of creating a new one.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.

- Create a vSphere Auto Deploy rule. See *Create a Deploy Rule*.
- If you want to include an image profile to the rule, verify that the software depot you need is added to the inventory. See *Add a Software Depot* or *Import a Software Depot*.

You can clone an existing vSphere Auto Deploy rule by using the Clone Deploy Rule wizard.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deploy Rules** tab, select a rule from the list.
3. Click **Clone**.
   The **Clone Deploy Rule** wizard appears.
4. On the **Name and hosts** page of the wizard, enter a name for the new rule.
5. Select to either apply the rule to all hosts in the inventory or only to hosts that match a specific pattern.
   You can select one or more patterns.
   For example, the rule can apply only to hosts in a vCenter Single Sign-On domain, with a specific host name, or that match a specific IPv4 range.
6. On the **Configuration** page of the wizard, you can optionally include items in the rule.
   Each enabled item adds a new page to the wizard.

Option	Action
Host Location	Add the hosts that match the criteria of the rule to a specific location, such as a cluster managed by a vSphere Lifecycle Manager image or by a vSphere Configuration Profile.
Image	Assign an image profile to the hosts that match the rule criteria.
Host Settings	Assign a host profile to the hosts that match the rule criteria.
Script Bundle	Assign a script bundle to the host that match the rule criteria.

7. On the **Select host location** page of the wizard, select a location for the hosts that match the rule.

Option	Action
If you want to keep the host location used in the cloned rule	Select the **Same Host location** check box.
If you want to select a new location for the selected hosts	1. Select the **Browse for Host location** check box. 2. Select a data center, folder, or cluster as host location. 3. Click **Next**.

8. On the **Select Image** page of the wizard, select an image profile.

Option	Action
If you do not want to change the image profile	Select the **Same image profile** check box.
If you want to assign a new image profile to the selected hosts	1. Select the **Browse for Image Profile** check box. 2. Select a software depot from the drop-down menu. 3. Select an image profile from the list. 4. (Optional) If you want to bypass the acceptance level verification for the image profile, select the **Skip image profile signature check** check box.

9. On the **Select host settings** page of the wizard, select a host profile.

Option	Action
If you want to keep the host profile used in the cloned rule	Select the **Same Host profile** check box.
If you want to assign a new host profile to the selected hosts	1. Select the **Browse for Host Profile** check box. 2. Select a host profile from the list and click **Next**.

10. On the **Select script bundle** page of the wizard, select a script bundle from the list.
11. On the **Ready to complete** page, review the summary information for the new rule.

- Activate a vSphere Auto Deploy rule. See *Activate, Deactivate, and Reorder Deploy Rules*.
- Edit a vSphere Auto Deploy rule. See *Edit a Deploy Rule*.

Edit a Deploy Rule

You can edit the name of an inactive Auto Deploy rule, its matching hosts, the host location, the image profile, and the host profile.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.
- Create a vSphere Auto Deploy rule. See *Create a Deploy Rule*.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deploy Rules** tab, from the list of rules in the inventory select the rule and click **Edit**.
   The Edit Deploy Rule dialog box appears.
3. Optional: On the **Name and hosts** page of the wizard, enter a new name for the rule.
4. Select to either apply the rule to all hosts in the inventory or only to hosts that match a specific pattern.
   You can select one or more patterns.
   For example, the rule can apply only to hosts in a vCenter Single Sign-On domain, with a specific host name, or that match a specific IPv4 range.
5. On the **Configuration** page of the wizard, you can optionally include items in the rule.
   Each enabled item adds a new page to the wizard.

Option	Action
Host Location	Add the hosts that match the criteria of the rule to a specific location, such as a cluster managed by a vSphere Lifecycle Manager image or by a vSphere Configuration Profile.
Image	Assign an image profile to the hosts that match the rule criteria.
Host Settings	Assign a host profile to the hosts that match the rule criteria.
Script Bundle	Assign a script bundle to the host that match the rule criteria.

6. On the **Select host location** page of the wizard, select a location for the hosts that match the rule.

Option	Action
If you want to keep the host location used in the cloned rule	Select the **Same Host location** check box.
If you want to select a new location for the selected hosts	1. Select the **Browse for Host location** check box. 2. Select a data center, folder, or cluster as host location. 3. Click **Next**.

7. On the **Select Image** page of the wizard, select an image profile.

Option	Action
If you do not want to change the image profile	Select the **Same image profile** check box.
If you want to assign a new image profile to the selected hosts	1. Select the **Browse for Image Profile** check box. 2. Select a software depot from the drop-down menu. 3. Select an image profile from the list. 4. (Optional) If you want to bypass the acceptance level verification for the image profile, select the **Skip image profile signature check** check box.

8. On the **Select host settings** page of the wizard, select a host profile.

Option	Action
If you want to keep the host profile used in the cloned rule	Select the **Same Host profile** check box.
If you want to assign a new host profile to the selected hosts	1. Select the **Browse for Host Profile** check box. 2. Select a host profile from the list and click **Next**.

9. On the **Select script bundle** page of the wizard, select a script bundle from the list.
10. On the **Ready to complete** page, review the summary information for the new rule.

- Activate a vSphere Auto Deploy rule. See *Activate, Deactivate, and Reorder Deploy Rules*.
- Clone a vSphere Auto Deploy rule. See *Clone a Deploy Rule*.

Activate, Deactivate, and Reorder Deploy Rules

After you create a vSphere Auto Deploy rule, the rule is in inactive state. You must activate the rule for it to take effect.

You can use the Activate and Reorder wizard to activate, deactivate, and change the order of the rules.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.
- Create a vSphere Auto Deploy rule. See *Create a Deploy Rule*.

The upper list on the **Activate and Reorder** page of the wizard displays the rules in the active rule set. The lower list displays the inactive rules.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deploy Rules** tab, click **Activate/Deactivate rules**.

   The Activate and Reorder wizard appears.
3. Optional: If you want to deactivate an active rule, select the rule from the active rules list and click the **Deactivate** button.
4. From the list of inactive rules, select the rule that you want to activate and click the **Activate** button.
5. Optional: If you want to reorder the rules in the active rule list, select a rule that you want to move up or down in the list and click **Move up** or **Move down** above the list of active rules.

   The rules are listed by priority. For example, if two or more rules apply to the same host but are set to provision the host with different host locations, image profiles, and host profiles, the rule that is highest in the list takes effect on the host.
6. Optional: If you want to test an inactive rule before activation, click **Test rules before activation**.
   a) Select a host from the list and click **Check Compliance** to view the current status of the host and the changes that are expected after the activation of the rule.

      If the host is compliant with the rule, you do not need to remediate the host after you activate the rule.

b) Optional: If you want to remediate the selected hosts after the rule activation, enable the toggle button or select the **Remediate all host associations after rule activation** check box to remediate all hosts.

7. Review the list of active rules and click **OK**.

On the **Deploy Rules** tab, the rule is listed as active in the Status column.

- View the host location, image profile, host profile, and added script bundles. See *View Host Associations*.
- Remediate non-compliant hosts. See *Remediate a Non-compliant Host*.

View Host Associations

Some ESX hosts in the vSphere Auto Deploy inventory might not be compliant with the active deploy rules and you must check for compliance.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.
- Create a vSphere Auto Deploy rule. See *Create a Deploy Rule*.
- Activate a vSphere Auto Deploy rule. See *Activate, Deactivate, and Reorder Deploy Rules*.

1. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.

2. Check the host associations compliance.

   The **Check Host Associations Compliance** window displays the status of the host and whether the host is compliant with the active rule set. You can view the currently assigned host location, image profile, host profile, script bundle, and the associations that will take effect after a remediation of the host.

Option	Steps
If you want to check the host associations compliance of a single host	1. On the **Deployed Hosts** tab, select an ESX host. 2. Click **Check Host Associations Compliance**. 3. Check if the host associations are compliant with the current active rule set. 4. If you want to remediate the host, click **Remediate**. 5. Close the **Check Host Associations Compliance** window.
If you want to check the host associations compliance of multiple hosts	1. On the **Deployed Hosts** tab, select multiple ESX hosts. 2. Click **Check Host Associations Compliance**. 3. Confirm that you want to check the compliance of all selected hosts. 4. Review the compliance status of the hosts in the left pane. 5. (Optional) Select a host to view the compliance status details. 6. (Optional) Select a host and click **Remediate** . 7. (Optional) Select the **Remediate all host associations after rule activation** check box to remediate all hosts. 8. **Close** the **Check Host Associations Compliance** window.

- Remediate non-compliant hosts. See *Remediate a Non-compliant Host*.
- Edit the image profile association of a host. See Edit the Image Profile Association of a Host.
- Edit a vSphere Auto Deploy rule. See *Edit a Deploy Rule*.

Edit the Image Profile Association of a Host

You can edit the image profile association of a single host if the host is not associated with a vSphere Auto Deploy rule.

Alternatively, you might not want to change the image profile association of multiple hosts by editing a rule.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.
- Create a vSphere Auto Deploy rule. See *Create a Deploy Rule*.
- Activate a vSphere Auto Deploy rule. See *Activate, Deactivate, and Reorder Deploy Rules*.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deployed Hosts** tab, select an ESX host.
3. Click **Edit Image Profile Association**.
   The Edit Image Profile Association dialog box appears.
4. Edit the image profile association of the host.

Option	Action
If you do not want to change the image profile	Select the **Same image profile** check box.
If you want to assign a new image profile to the selected hosts	1. Select the **Browse for Image Profile** check box. 2. Select a software depot from the drop-down menu. 3. Select an image profile from the list. 4. (Optional) If you want to bypass the acceptance level verification for the image profile, select the **Skip image profile signature check** check box.

5. Click **OK**.

The new image profile is listed in the Associated Image Profile column after a refresh of the page.

- View the host location, image profile, host profile, and added script bundles. See *View Host Associations*.
- If the host is associated with a rule and you want to revert to the image profile defined in the rule, remediate the host. See Remediate a Non-compliant Host.

Remediate a Non-compliant Host

Remediate the ESX host associations when you add a rule to the vSphere Auto Deploy active rule set or make changes to one or more rules.

When you add a rule to the vSphere Auto Deploy active rule set or make changes to one or more rules, hosts are not updated automatically. You must remediate the host associations to apply the new rules to the host.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.
- Create a vSphere Auto Deploy rule. See *Create a Deploy Rule*.
- Activate a vSphere Auto Deploy rule. See *Activate, Deactivate, and Reorder Deploy Rules*.
- If the remediation of a host, results in a change in its location, the host must be placed in maintenance mode.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deployed Hosts** tab, select a single or multiple ESX hosts.
3. Click **Remediate Host Associations**.
   If you remediate a host that has an edited image profile association, the host reverts to the settings defined in the rule that it matches.
   You can monitor the progress of the remediation process in the Recent Tasks pane.

- View the host location, image profile, host profile, and added script bundles. See *View Host Associations*.
- Change the image profile association of a host. See *Edit the Image Profile Association of a Host*.

Add a Host to the vSphere Auto Deploy Inventory

You can view the hosts that do not match any vSphere Auto Deploy rule and manually add a host to the vSphere Auto Deploy inventory.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy*.

- To assign an image profile to the host, add the software depot that you need to the inventory. See Add a Software Depot or Import a Software Depot.

To add a host to the current vSphere Auto Deploy inventory of deployed hosts, you can create a new rule or edit an existing rule to include a host that is not deployed with vSphere Auto Deploy and associate it with a specific host location, image profile, host profile, and script bundle. Alternatively, you can manually add a host to the inventory by assigning it a host location, image profile, host profile, and script bundle.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Discovered Hosts** tab, select one or more hosts that you want to provision with a host location, image profile, and host profile.
3. Select **Add to Inventory**.
   Alternatively, click **Remove** to dismiss the selected hosts from the **Discovered Hosts** tab.
   The Add to Inventory wizard appears.
4. On the **Select host location** page of the wizard, select a data center, folder, or cluster as host location for the hosts that match the rule. With ESX 9.0, support for stateless installs is deprecated and along with host location, you must define the type of hosts that the rule deploys. Select the Stateless (Network boot) option under **Applicability** if you want to create stateless hosts.
5. On the **Select Image** page of the wizard, use the drop-down menu to select a software depot and choose an image profile from the list.
   If you want to bypass the acceptance level verification for the image profile, select the **Skip image profile signature check** check box.
6. On the **Select host settings** page of the wizard, select a host profile from the list.
7. On the **Select host profile** page of the wizard, use the **Filter** to search the host profiles list or select the **Do not include a host profile** check box to continue without adding a host profile.
8. On the **Select script bundle** page of the wizard, select a script bundle from the list.
9. On the Ready to complete page, review the selected host associations.

- Edit a vSphere Auto Deploy rule. See *Edit a Deploy Rule*.
- Clone a vSphere Auto Deploy rule. See *Clone a Deploy Rule*.
- View the host location, image profile, host profile, and added script bundles. See *View Host Associations*.
- Remediate non-compliant hosts. See *Remediate a Non-compliant Host*.

Add a Host to a Cluster That Uses a Single Image

Create a rule in Auto Deploy that assigns a cluster that you manage by a single image as the host location for newly added ESX hosts.

To add ESX hosts to a cluster that you manage by a single image, you create a rule in Auto Deploy that assigns such a cluster as the host location for newly added hosts. Each host inherits the same image, which enables hardware compatibility checking, cluster-wide remediation, and easier upgrades.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy* in the *VMware ESX Installation and Setup* documentation.
- Verify that each ESX host is version 8.0 or later.
- Verify that all hosts in the cluster are stateful and have a physical storage attached.
- Verify that solutions, which are not integrated with vSphere Lifecycle Manager are not enabled for the cluster.

By creating an Auto Deploy rule, where the host target location is a cluster managed by an image, you can transition stateful ESX hosts to the cluster. Based on host identification mechanisms, the rule adds the hosts to the target cluster.

Such Auto Deploy rule is not allowed to contain an Image Profile or a Host Profile, as the image specification and configuration of hosts in the target cluster are created automatically.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deploy Rules** tab, click **New Deploy Rule**.
   The **New Deploy Rule** wizard appears.
3. On the **Name and hosts** page of the wizard, enter a name for the new rule.
4. Select to either apply the rule to all hosts in the inventory or only to hosts that match a specific pattern.
   You can select one or more patterns.
   For example, the rule can apply only to hosts in a vCenter Single Sign-On domain, with a specific host name, or that match a specific IPv4 range.
5. On the **Configuration** page of the wizard, select the **Host Location** check box, and click **Next**.
   You can optionally include a script bundle to the ESX hosts that match the rule criteria by selecting the **Script Bundle** check box.

   Note:
   The image profile and host profile attached to the target cluster are used.
6. On the **Select host location** page of the wizard, select a cluster that uses a single image.
7. On the **Select script bundle** page of the wizard, select a script bundle from the list.
8. On the **Ready to complete** page, review the summary information for the new rule.
9. Click **Finish**.

You can view the newly created rule listed on the **Deploy Rules** tab.

- Activate a vSphere Auto Deploy rule. See Activate, Deactivate, and Reorder Deploy Rules.
- For more information on stateless caching and stateful installations, see Use vSphere Auto Deploy for Stateless Caching and Stateful Installs.

Add a Host to a Cluster Managed by vSphere Configuration Profiles

Create an Auto Deploy rule that assigns newly added hosts to a cluster that manages ESX configuration collectively with vSphere Configuration Profiles.

To add ESX hosts to a cluster that manages ESX configuration at a cluster level, you create a rule in Auto Deploy that assigns such a cluster as the host location for newly added hosts, which inherit the same settings and do not require manual configuration.

- Prepare your system and install the Auto Deploy Server. For more information, see Install and Configure vSphere Auto Deploy.
- Verify that each ESX host is version 8.0 or later.

Note:

Starting with VCF 9.1, Auto Deploy supports provisioning bare-metal hosts with vSphere Distributed Switch (DVS) and NSX settings in vSphere Configuration Profile (VCP) clusters.

By creating an Auto Deploy rule to manage the configuration of all hosts collectively by using vSphere Configuration Profiles on a cluster level, you remove the need to use Host Profiles or manual configurations. At the same time, you keep the flexibility to define custom settings per host or override the cluster-level settings for a group of hosts. For more information on how to set up clusters that you manage with a configuration at a cluster level, see What is vSphere Configuration Profiles.

Before you start using Auto Deploy with vSphere Configuration Profiles, you must have a ready configuration, either in a `.json` file or imported from a reference host. The best practice is to:

- Create a VCP cluster.
- Manually configure the desired settings on an existing ESX host that you select as a reference host.
- Import the reference host configuration to create a draft, make changes, precheck, and apply it.

Successful provisioning of hosts in VCP clusters requires a valid, non-empty desired configuration document. If the cluster configuration lacks networking details, Auto Deploy rules might fail, because hosts cannot come online. Always validate the configuration before you create Auto Deploy rules and attempt to provision hosts.

Note:

Once you set up a cluster that manages ESX configuration at a cluster level, you cannot roll back to using Host Profiles or single images, and you cannot use the Quickstart option for such clusters. However, you can switch from a cluster that you manage with a single image to a cluster that you manage with a configuration at a cluster level just by selecting the **Set Up Host Settings** option under **Configure** > **Desired State** > **Host Settings**.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deploy Rules** tab, click **New Deploy Rule**.
   The **New Deploy Rule** wizard appears.
3. On the **Name and hosts** page of the wizard, enter a name for the new rule.
4. Select to either apply the rule to all hosts in the inventory or only to hosts that match a specific pattern.
   You can select one or more patterns.
   For example, the rule can apply only to hosts in a vCenter Single Sign-On domain, with a specific host name, or that match a specific IPv4 range.
5. On the **Configuration** page of the wizard, select the **Host Location** check box, and click **Next**.
   You can ignore the **Image**, **Host Settings**, and **Script Bundle** check boxes. Image specification and configuration of hosts in the target cluster, and any post-installation settings, are created automatically. Even if you select any of the check boxes, the rule ignores the selections.
6. On the **Select host location** page of the wizard, select a cluster that manages ESX configuration at a cluster level.
7. On the **Ready to complete** page, review the summary information for the new rule.
8. Click **Finish**.

You can view the newly created rule listed on the **Deploy Rules** tab.

- Activate a vSphere Auto Deploy rule. See Activate, Deactivate, and Reorder Deploy Rules.
- For more information on stateless caching and stateful installs, see Use vSphere Auto Deploy for Stateless Caching and Stateful Installs.

Working with Script Bundles

You can add a custom script for additional post-deployment host configuration. The script runs after you provision an ESX host with Auto Deploy. For example, you can create a custom ESX firewall rule and other configurations not available with Host Profiles.

- Verify that you can run the script in the ESX Shell.

Since ESX 6.7 Update 1, you can add or remove a custom script by using the vSphere Client. A script bundle can include multiple scripts and must be delivered as a single compressed file with the `.tgz` extension. After uploaded to the vCenter, you can include the script bundle to an Auto Deploy rule.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. Select the **Script Bundles** tab.
3. Click **Upload**.
4. Browse to a script bundle file and select **Upload**.
   The script is present in the **Script Bundles** list.

5. Optional: Select a script bundle, click **Remove**, and confirm the selection.
   The script bundle is deleted from the list.

- Activate a vSphere Auto Deploy rule. See *Activate, Deactivate, and Reorder Deploy Rules*.
- Edit a vSphere Auto Deploy rule. See *Edit a Deploy Rule*.
- Clone a vSphere Auto Deploy rule. See *Clone a Deploy Rule*.
- View the host location, image profile, host profile, and added script bundles. See *View Host Associations*.
- Remediate non-compliant hosts. See *Remediate a Non-compliant Host*.
- Change the image profile association of a host. See *Edit the Image Profile Association of a Host*.

Download vSphere Auto Deploy Logs

You can use the vSphere Auto Deploy logging information from the vSphere Client to resolve problems that you encounter with vSphere Auto Deploy.

Use the vSphere Client to log in to the vCenter instance that vSphere Auto Deploy is registered with.

1. Navigate to **Home** > **Administration** and select **Deployment** > **System Configuration**.
2. Select one of the nodes for which you want to retrieve a support bundle. The support bundle holds the services logs.
3. Click **Export Support Bundle**.
4. Select only **VirtualAppliance** > **Auto Deploy**.
5. At **Select information to include**, select a custom support bundle.
6. Click **Export** to download the log files.

Start, Stop, or Restart the vSphere Auto Deploy Service

You can start, stop, or restart the Auto Deploy service in the vCenter Management Interface.

Verify that you have a root access to the vCenter Management Interface.

To start, stop, and restart services in vCenter, you use the vCenter Management Interface.

1. Log in to the vCenter Management Interface, https://*IP-address-or-FQDN*:5480.
2. Click **Services**.
   The **Services** pane displays a table of all installed services. You can sort them by name, startup type, health, and state.
3. Select the **Auto Deploy** service and select your action.
   The available actions depend on whether the Auto Deploy service is already running or not.
   - Click **Restart** to restart the service.
     Restarting the service requires confirmation and might lead to the Auto Deploy functionality becoming temporarily unavailable.
   - Click **Start** to start the service.
   - Click **Stop** to stop the service.
     Stopping the service requires confirmation.

Provision ESX Hosts with vSphere Auto Deploy

Use vSphere Auto Deploy to provision or reprovision hundreds of physical hosts with ESX software.

You can use vSphere Auto Deploy to provision hundreds of physical hosts with ESX software either for the first time (first boot), or reboot hosts, or reprovision hosts with a different image profile, host profile, custom script, or folder, or cluster location. You can also select to provision the hosts with an image profile that does not contain VMware Tools binaries.

- vSphere Auto Deploy Boot Process

- Reprovisioning Hosts
- Provision ESX Host with an Image Profile Without VMware Tools

vSphere Auto Deploy Boot Process

When you boot a host that you want to provision or reprovision with vSphere Auto Deploy, the vSphere Auto Deploy infrastructure supplies the image profile and, optionally, a host profile, a vCenter location, and script bundle for that host.

The boot process is different for hosts that have not yet been provisioned with vSphere Auto Deploy (first boot) and for hosts that have been provisioned with vSphere Auto Deploy and added to a vCenter system (subsequent boot).

First Boot Prerequisites

Before a first boot process, you must set up your system. Setup includes the following tasks, which are discussed in more detail in Install and Configure vSphere Auto Deploy.

- Set up a DHCP server that assigns an IP address to each host upon startup and that points the host to the TFTP server to download the iPXE boot loader from.
- If the hosts that you plan to provision with vSphere Auto Deploy are with legacy BIOS, verify that the vSphere Auto Deploy server has an IPv4 address. PXE booting with legacy BIOS firmware is possible only over IPv4. PXE booting with UEFI firmware is possible with either IPv4 or IPv6.
- Identify an image profile to be used in one of the following ways.
  - Choose an ESX image profile in a public depot.
  - Create a custom image profile by using vSphere ESX Image Builder, and place the image profile in a depot that the vSphere Auto Deploy server can access. The image profile must include a base ESX VIB.
- If you have a reference host in your environment, export the host profile of the reference host and define a rule that applies the host profile to one or more hosts. See Setting Up a vSphere Auto Deploy Reference Host.
- Specify rules for the deployment of the host and add the rules to the active rule set.

First Boot Overview

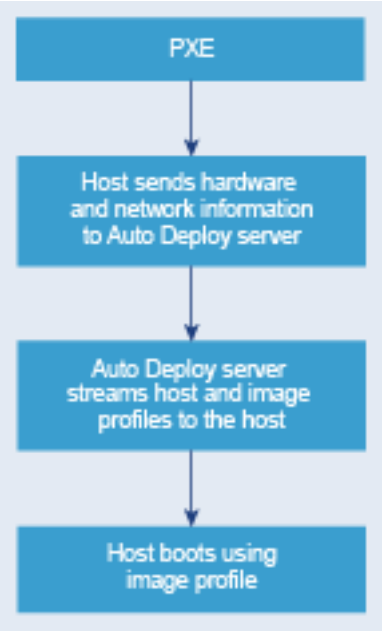
When a host that has not yet been provisioned with vSphere Auto Deploy boots (first boot), the host interacts with several vSphere Auto Deploy components.

1. When the administrator turns on a host, the host starts a PXE boot sequence.
   The DHCP Server assigns an IP address to the host and instructs the host to contact the TFTP server.
2. The host contacts the TFTP server and downloads the iPXE file (executable boot loader) and an iPXE configuration file.
3. iPXE starts executing.
   The configuration file instructs the host to make a HTTP boot request to the vSphere Auto Deploy server. The HTTP request includes hardware and network information.
4. In response, the vSphere Auto Deploy server performs these tasks:
   a. Queries the rules engine for information about the host.
   b. Streams the components specified in the image profile, the optional host profile, and optional vCenter location information.
5. The host boots using the image profile.
   If the vSphere Auto Deploy server provided a host profile, the host profile is applied to the host.
6. vSphere Auto Deploy adds the host to the vCenter system that vSphere Auto Deploy is registered with.
   a. If a rule specifies a target folder or cluster on the vCenter system, the host is placed in that folder or cluster. The target folder must be under a data center.
   b. If no rule exists that specifies a vCenter inventory location, vSphere Auto Deploy adds the host to the first datacenter displayed in the vSphere Client UI.
7. If the host profile requires the user to specify certain information, such as a static IP address, the host is placed in maintenance mode when the host is added to the vCenter system.
   You must reapply the host profile and update the host customization to have the host exit maintenance mode. When you update the host customization, answer any questions when prompted.

8. If the host is part of a DRS cluster, virtual machines from other hosts might be migrated to the host after the host has successfully been added to the vCenter system.

See Provision a Host (First Boot).

Figure 7: vSphere Auto Deploy Installation, First Boot



Subsequent Boots Without Updates

For hosts that are provisioned with vSphere Auto Deploy and managed by vCenter, subsequent boots can become completely automatic.

1. The administrator reboots the host.
2. As the host boots up, vSphere Auto Deploy provisions the host with its image profile and host profile.
3. Virtual machines are brought up or migrated to the host based on the settings of the host.
   - Standalone host. Virtual machines are powered on according to autostart rules defined on the host.
   - DRS cluster host. Virtual machines that were successfully migrated to other hosts stay there. Virtual machines for which no host had enough resources are registered to the rebooted host.

If vCenter is not responsive, the host contacts the vSphere Auto Deploy server and is provisioned with an image profile. The host continues to contact the vSphere Auto Deploy server until vSphere Auto Deploy reconnects to the vCenter.

vSphere Auto Deploy cannot set up vSphere distributed switches if vCenter is not responsive, and virtual machines are assigned to hosts only if they participate in an vSphere HA cluster. Until the host is reconnected to vCenter and the host profile is applied, the switch cannot be created. Because the host is in maintenance mode, virtual machines cannot start. See Reprovision Hosts with Simple Reboot Operations.

Any hosts that are set up to require user input are placed in maintenance mode. See Update the Host Customization in the vSphere Client.

Subsequent Boots With Updates

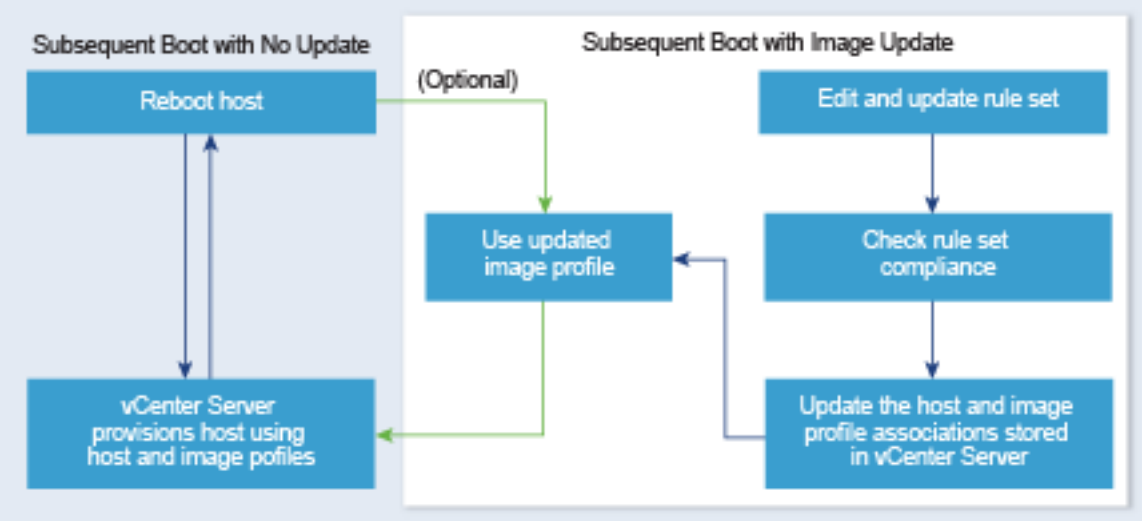
You can change the image profile, host profile, vCenter location, or script bundle for hosts. The process includes changing rules and testing and repairing the host's rule compliance.

1. The administrator uses the `Copy-DeployRule`VCF PowerCLI cmdlet to copy and edit one or more rules and updates the rule set. See Overview of the vSphere Auto Deploy Process by Using VCF PowerCLI for an example.
2. The administrator runs the `Test-DeployRulesetCompliance` cmdlet to check whether each host is using the information that the current rule set specifies.
3. The host returns a VCF PowerCLI object that encapsulates compliance information.

4. The administrator runs the `Repair-DeployRulesetCompliance` cmdlet to update the image profile, host profile, or vCenter location the vCenter system stores for each host.
5. When the host reboots, it uses the updated image profile, host profile, vCenter location, or script bundle for the host.
   If the host profile is set up to request user input, the host is placed in maintenance mode. Follow the steps in Update the Host Customization in the vSphere Client.

See Test and Repair Rule Compliance .

Figure 8: vSphere Auto Deploy Installation, Subsequent Boots



Provisioning of Systems that Have Distributed Switches

You can configure the host profile of a vSphere Auto Deploy reference host with a distributed switch.

When you configure the distributed switch, the boot configuration parameters policy is automatically set to match the network parameters required for host connectivity after a reboot.

When vSphere Auto Deploy provisions the ESX host with the host profile, the host goes through a two-step process.

1. The host creates a standard virtual switch with the properties specified in the boot configuration parameters field.
2. The host creates the VMkernel NICs. The VMkernel NICs allow the host to connect to vSphere Auto Deploy and to the vCenter system.

When the host is added to vCenter, vCenter removes the standard switch and reapplies the distributed switch to the host.

> **Note:**
> Do not change the boot configuration parameters to avoid problems with your distributed switch.

Provision a Host (First Boot)

Provisioning a host that has never been provisioned with vSphere Auto Deploy (first boot) differs from subsequent boot processes. You must prepare the host and fulfill all other prerequisites before you can provision the host. You can optionally define a custom image profile with vSphere ESX Image Builder by using the vSphere Client or VCF PowerCLI cmdlets.

- Make sure your host meets the hardware requirements for ESX hosts.
  See ESX Hardware Requirements.
- Prepare the system for vSphere Auto Deploy. See Install and Configure vSphere Auto Deploy.
- Write rules that assign an image profile to the host and optionally assign a host profile and a vCenter location to the host. See
  How vSphere Auto Deploy Works with VCF PowerCLI or Managing vSphere Auto Deploy with the vSphere Client.
  When the setup is complete, the vSphere Auto Deploy service is enabled, DHCP setup is complete, and rules for the host that you want to provision are in the active rule set.

1. Turn on the host.

   The host contacts the DHCP server and downloads iPXE from the location the server points it to. Next, the vSphere Auto Deploy server provisions the host with the image specified by the rule engine. The vSphere Auto Deploy server might also apply a host profile to the host if one is specified in the rule set. Finally, vSphere Auto Deploy adds the host to the vCenter system that is specified in the rule set.

2. Optional: If vSphere Auto Deploy applies a host profile that requires user input such as an IP address, the host is placed in maintenance mode. Reapply the host profile with the vSphere Client and provide the user input when prompted.

After the first boot process, the host is running and managed by a vCenter system. The vCenter stores the host's image profile, host profile, and location information.

You can now reboot the host as needed. Each time you reboot, the host is reprovisioned by the vCenter system.

Reprovision hosts as needed. See Reprovisioning Hosts.

If you want to change the image profile, host profile, custom script, or location of the host, update the rules and activate them by using the vSphere Client or perform a test and repair compliance operation in a VCF PowerCLI session. See Rules and Rule Sets or Test and Repair Rule Compliance .

Reprovisioning Hosts

Use vSphere Auto Deploy to reprovision ESX hosts with a different image profile or a different host profile.

vSphere Auto Deploy supports multiple reprovisioning options. You can perform a simple reboot or reprovision with a different image profile or a different host profile.

A first boot using vSphere Auto Deploy requires that you set up your environment and add rules to the rule set. See Install and Configure vSphere Auto Deploy.

The following reprovisioning operations are available.

- Simple reboot.
- Reboot of hosts for which the user answered questions during the boot operation.
- Reprovision with a different image profile.
- Reprovision with a different host profile.

Reprovision Hosts with Simple Reboot Operations

You can reprovision ESX hosts with the image profile, host profile, custom script, and vCenter location assigned during first boot.

A simple reboot of a host that is provisioned with vSphere Auto Deploy requires only that all prerequisites are still met. The process uses the previously assigned image profile, host profile, custom script, and vCenter location.

- Verify that the setup you performed during the first boot operation is in place. See Provision a Host (First Boot).
- Verify that all associated items like are available. An item can be an image profile, host profile, custom script or vCenter inventory location.
- Verify that the host has the identifying information (asset tag, IP address) it had during previous boot operations.

1. Place the host in maintenance mode.

Host Type	Action
Host is part of a DRS cluster	VMware DRS migrates virtual machines to appropriate hosts when you place the host in maintenance mode.
Host is not part of a DRS cluster	You must migrate all virtual machines to different hosts and place each host in maintenance mode.

2. Reboot the host.

The host shuts down. When the host reboots, it uses the image profile that the vSphere Auto Deploy server provides. The vSphere Auto Deploy server also applies the host profile stored on the vCenter system.

Use VCF PowerCLI To Reprovision a Host

You can use vSphere Auto Deploy to reprovision a host with a new image profile in a VCF PowerCLI session.

- Verify that the image profile you want to use to reprovision the host is available. Use vSphere ESX Image Builder in a VCF PowerCLI session. See Customizing Installations with vSphere ESX Image BuilderCustomizing Installations with vSphere ESX Image Builder.
- Verify that the setup you performed during the first boot operation is in place.

Several options for reprovisioning hosts exist.

- If the VIBs that you want to use support live update, you can use an `esxcli software vib update` command. In that case, you must also update the rule set to use an image profile that includes the new VIBs.
- During testing, you can apply an image profile to an individual host with the `Apply-EsxImageProfile` cmdlet and reboot the host so the change takes effect. The `Apply-EsxImageProfile` cmdlet updates the association between the host and the image profile but does not install VIBs on the host.
- In all other cases, use this procedure.

1. At the PowerShell prompt, run the `Connect-VIServer` VCF PowerCLI cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_or_ipv6_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate warnings result. In a development environment, you can ignore the warning.

2. Determine the location of a public software depot that contains the image profile that you want to use, or define a custom image profile with vSphere ESX Image Builder.

3. Run `Add-EsxSoftwareDepot` to add the software depot that contains the image profile to the VCF PowerCLI session.

Depot Type	Cmdlet
Remote depot	Run `Add-EsxSoftwareDepot` *`depot_url`*.
ZIP file	1. Download the ZIP file to a local file path or create a mount point local to the VCF PowerCLI machine. 2. Run `Add-EsxSoftwareDepot C:\`*`file_path`*`\`*`my_offline_depot`*`.zip`.

4. Run `Get-EsxImageProfile` to see a list of image profiles, and decide which profile you want to use.

5. Run `Copy-DeployRule` and specify the `ReplaceItem` parameter to change the rule that assigns an image profile to hosts.

   The following cmdlet replaces the current image profile that the rule assigns to the host with the *`my_new_imageprofile`* profile. After the cmdlet completes, `myrule` assigns the new image profile to hosts. The old version of `myrule` is renamed and hidden.

   ```
   Copy-DeployRule myrule -ReplaceItemmy_new_imageprofile
   ```

6. Test the rule compliance for each host that you want to deploy the image to.

   a) Verify that you can access the host for which you want to test rule set compliance.

   ```
   Get-VMHost-NameESX_hostname
   ```

   b) Run the cmdlet that tests rule set compliance for the host, and bind the return value to a variable for later use.

   ```
   $tr = Test-DeployRuleSetComplianceESX_hostname
   ```

   c) Examine the differences between the contents of the rule set and configuration of the host.

   ```
   $tr.itemlist
   ```

   The system returns a table of current and expected items if the host for which you want to test the new rule set compliance is compliant with the active rule set.

   ```
   CurrentItem                          ExpectedItem
   -----------                          ------------
    my_old_imageprofilemy_new_imageprofile
   ```

d) Remediate the host to use the revised rule set the next time you boot the host.

```
Repair-DeployRuleSetCompliance $tr
```

7. Reboot the host to provision it with the new image profile.

Reprovision a Host with a New Image Profile by Using the vSphere Client

You can use vSphere Auto Deploy to reprovision a host with a new image profile with the vSphere Client by changing the rule that the host corresponds to and activating the rule.

- Verify that the image profile you want to use to reprovision the host is available. See Create an Image Profile.
- Verify that the setup you performed during the first boot operation is in place.

1. Navigate to **Home** > **Auto Deploy**.
   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
2. On the **Deploy Rules** tab, from the list of rules in the inventory select the rule and click **Edit**.
   The Edit Deploy Rule dialog box appears.
3. Optional: On the **Name and hosts** page of the wizard, enter a name for the new rule.
4. Optional: Select to either apply the rule to all hosts in the inventory or only to hosts that match a specific pattern.
   You can select one or more patterns.
   For example, the rule can apply only to hosts in a vCenter Single Sign-On domain, with a specific host name, or that match a specific IPv4 range.
5. On the **Configuration** page of the wizard, you can optionally include items in the rule.
   Each enabled item adds a new page to the wizard.

Option	Action
Host Location	Add the hosts that match the criteria of the rule to a specific location, such as a cluster managed by a vSphere Lifecycle Manager image or by a vSphere Configuration Profile.
Image	Assign an image profile to the hosts that match the rule criteria.
Host Settings	Assign a host profile to the hosts that match the rule criteria.
Script Bundle	Assign a script bundle to the host that match the rule criteria.

6. Click **Next** to skip the Host Location selection.
7. On the **Select image profile** page of the wizard, assign an image profile to the hosts that match the rule criteria.

Option	Action
If you do not want to change the image profile	Select the **Same image profile** check box.
If you want to assign a new image profile to the selected hosts	1. Select the **Browse for Image Profile** check box. 2. Select a software depot from the drop-down menu. 3. Select an image profile from the list. 4. (Optional) If you want to bypass the acceptance level verification for the image profile, select the **Skip image profile signature check** check box.

8. Click **Next** to skip the Host profile selection.
9. On the **Ready to complete** page, review the summary information for the new image profile and click **Finish**.
10. Click **Activate/Deactivate rules**.
11. From the list of inactive rules, select the rule that you want to activate and click the **Activate** button.
12. Optional: If you want to reorder the rules in the active rule list, select a rule that you want to move up or down in the list and click **Move up** or **Move down** above the list of active rules.

    The rules are listed by priority. For example, if two or more rules apply to the same host but are set to provision the host with different host locations, image profiles, and host profiles, the rule that is highest in the list takes effect on the host.
13. Optional: If you want to test an inactive rule before activation, click **Test rules before activation**.
    a) Select a host from the list and click **Check Compliance** to view the current status of the host and the changes that are expected after the activation of the rule.

       If the host is compliant with the rule, you do not need to remediate the host after you activate the rule.
    b) Optional: If you want to remediate the selected hosts after the rule activation, enable the toggle button or select the **Remediate all host associations after rule activation** check box to remediate all hosts.
14. Review the list of active rules and click **OK**.
15. Reboot the host to provision it with the new image profile.

Update the Host Customization in the vSphere Client

If a host required user input during a previous boot, the answers are saved with the vCenter. If you want to prompt the user for new information, you must remediate the host.

Attach a host profile that prompts for user input to the host.

1. Migrate all virtual machines to different hosts, and place the host into maintenance mode.

Host Type	Action
Host is part of a DRS cluster	VMware DRS migrates virtual machines to appropriate hosts when you place the host in maintenance mode.
Host is not part of a DRS cluster	You must migrate all virtual machines to different hosts and place each host in maintenance mode.

2. Navigate to **Home** > **Auto Deploy**.

   By default, only the administrator role has privileges to use the vSphere Auto Deploy service.
3. On the **Deployed Hosts** tab, select an ESX host.
4. Click **Remediate Host Associations**.

   You can monitor the progress of the remediation process in the Recent Tasks pane.
5. When prompted, provide the user input.
6. Direct the host to exit maintenance mode.

The host customization is saved and takes effect the next time you boot the host.

Provision ESX Host with an Image Profile Without VMware Tools

You can select to provision ESX hosts with an image profile that does not contain VMware Tools binaries.

When you provision ESX hosts with vSphere Auto Deploy, you can select to provision the hosts with an image profile that does not contain VMware Tools binaries. This image profile is smaller, has a lower memory overhead, and boots faster in a PXE-boot environment.

Download the *xxxxx*`-no-tools` image profile from the Broadcom Support Portal.

If the network boot time is too slow when using the standard image, or if you want to save space on the hosts, you can use an image profile that does not include VMware Tools and place the VMware Tools binaries on a shared storage.

1. Boot an ESX host that was not provisioned with vSphere Auto Deploy.
2. Copy the `/productLocker` directory from the ESX host to a shared storage.

   You can connect to an ESX host using an SSH client.
3. Change the *`UserVars.ProductLockerLocation`* variable to point to the new `/productLocker` directory location.
   a) In the vSphere Client, select the reference host and click the **Configure** tab.
   b) Under **System**, click **Advanced System Settings**.
   c) Click **Edit**.
   d) Filter the settings for `uservars`, and select **UserVars.ProductLockerLocation**.
   e) Click the current value and edit the location so it points to the shared storage.
4. Create a host profile from the reference host.
5. Create a vSphere Auto Deploy rule that assigns the *`xxxxx`*`-no-tools` image profile and host profile from the reference host to all other hosts.
6. Boot your target hosts with the rule so they pick up the product locker location from the reference host.

Use vSphere Auto Deploy for Stateless Caching and Stateful Installs

With stateless caching, you can cache the image of an ESX host. With stateful installs, you can install hosts over the network.

The vSphere Auto Deploy stateless caching feature lets you cache the host's image. The vSphere Auto Deploy stateful installs feature lets you install hosts over the network. After the initial network boot, these hosts boot like other ESX hosts. The stateless caching solution is primarily intended for situations when several hosts boot simultaneously. The locally cached image helps prevent a bottleneck that results if several hundreds of hosts connect to the vSphere Auto Deploy server simultaneously. After the boot operation is complete, hosts connect to vSphere Auto Deploy to complete the setup.

The stateful installs feature lets you provision hosts with the image profile over the network without having to set up the PXE boot infrastructure.

Introduction to Stateless Caching and Stateful Installs

You can use the System Cache Configuration host profile to provision hosts with vSphere Auto Deploy stateless caching and stateful installs.

Examples of Stateless Caching and Stateful Installs

Hosts provisioned with vSphere Auto Deploy cache the image (stateless caching)	Set up and apply a host profile for stateless caching. You can cache the image on a local disk, a remote disk, or a USB drive. Continue provisioning this host with vSphere Auto Deploy. If the vSphere Auto Deploy server becomes unavailable, for example because hundreds of hosts attempt to access it simultaneously, the host boots from the cache. The host attempts to reach the vSphere Auto Deploy server after the boot operation to complete configuration.
Hosts provisioned with vSphere Auto Deploy become stateful hosts	Set up and apply a host profile for stateful installs. When you provision a host with vSphere Auto Deploy, the image is installed on the local disk, a remote disk, or a USB drive. For subsequent boots, you boot from the disk. The host no longer uses vSphere Auto Deploy.

Preparation

To successfully use stateless caching or stateful installs, decide how to configure the system and set the boot order.

Table 22: Preparation for Stateless Caching or Stateful Installs

Requirement or Decision	Description
Decide on VMFS partition overwrite	When you install ESX by using the interactive installer, you are prompted whether you want to overwrite an existing VMFS datastore. The System Cache Configuration host profile provides an option to overwrite existing VMFS partitions. The option is not available if you set up the host profile to use a USB drive.
Decide whether you need a highly available environment	If you use vSphere Auto Deploy with stateless caching, you can set up a highly available vSphere Auto Deploy environment to guarantee that virtual machines are migrated on newly provisioned hosts and that the environment supports vSphere Distributed Switch even if the vCenter system becomes temporarily unavailable.
Set the boot order	The boot order you specify for your hosts depends on the feature you want to use. • To set up vSphere Auto Deploy with stateless caching, configure your host to first attempt to boot from the network, and to then attempt to boot from disk. If the vSphere Auto Deploy server is not available, the host boots using the cache. • To set up vSphere Auto Deploy for stateful installs on hosts that do not currently have a bootable disk, configure your hosts to first attempt to boot from disk, and to then attempt to boot from the network. **Note:** If you currently have a bootable image on the disk, configure the hosts for one-time PXE boot, and provision the host with vSphere Auto Deploy to use a host profile that specifies stateful installs.

Stateless Caching and Loss of Connectivity

If the ESX hosts that run your virtual machines lose connectivity to the vSphere Auto Deploy server, the vCenter system, or both, some limitations apply the next time you reboot the host.

- If vCenter is available but the vSphere Auto Deploy server is unavailable, hosts do not connect to the vCenter system automatically. You can manually connect the hosts to the vCenter, or wait until the vSphere Auto Deploy server is available again.
- If both vCenter and vSphere Auto Deploy are unavailable, you can connect to each ESX host by using the VMware Host Client, and add virtual machines to each host.
- If vCenter is not available, vSphere DRS does not work. The vSphere Auto Deploy server cannot add hosts to the vCenter. You can connect to each ESX host by using the VMware Host Client, and add virtual machines to each host.
- If you make changes to your setup while connectivity is lost, the changes are lost when the connection to the vSphere Auto Deploy server is restored.

Understanding Stateless Caching and Stateful Installs

When you want to use vSphere Auto Deploy with stateless caching or stateful installs, you must set up a host profile, apply the host profile, and set the boot order.

When you apply a host profile that enables caching to a host, vSphere Auto Deploy partitions the specified disk. What happens next depends on how you set up the host profile and how you set the boot order on the host.

- vSphere Auto Deploy caches the image when you apply the host profile if **Enable stateless caching on the host** is selected in the System Cache Configuration host profile. No reboot is required. When you later reboot, the host

continues to use the vSphere Auto Deploy infrastructure to retrieve its image. If the vSphere Auto Deploy server is not available, the host uses the cached image.

- vSphere Auto Deploy installs the image if **Enable stateful installs on the host** is selected in the System Cache Configuration host profile. When you reboot, the host initially boots using vSphere Auto Deploy to complete the installation. A reboot is then issued automatically, after which the host boots from disk, similar to a host that was provisioned with the installer. vSphere Auto Deploy no longer provisions the host.

You can apply the host profile from the vSphere Client, or write a vSphere Auto Deploy rule in a VCF PowerCLI session that applies the host profile.

Using the vSphere Client to Set Up vSphere Auto Deploy for Stateless Caching or Stateful Installs

You can create a host profile on a reference host and apply that host profile to additional hosts or to a vCenter folder or cluster. The following workflow results.

1. You provision a host with vSphere Auto Deploy and edit that host's System Image Cache Configuration host profile.
2. You place one or more target hosts in maintenance mode, apply the host profile to each host, and instruct the host to exit maintenance mode.
3. What happens next depends on the host profile you selected.
   - If the host profile enabled stateless caching, the image is cached to disk. No reboot is required.
   - If the host profile enabled stateful installs, the image is installed. When you reboot, the host uses the installed image.

Using VCF PowerCLI to Set Up vSphere Auto Deploy for Stateless Caching or Stateful Installs

You can create a host profile for a reference host and write a vSphere Auto Deploy rule that applies that host profile to other target hosts in a VCF PowerCLI session. The following workflow results.

1. You provision a reference host with vSphere Auto Deploy and create a host profile to enable a form of caching.
2. You write a rule that provisions additional hosts with vSphere Auto Deploy and that applies the host profile of the reference host to those hosts.
3. vSphere Auto Deploy provisions each host with the image profile or by using the script bundle associated with the rule. The exact effect of applying the host profile depends on the host profile you selected.
   - For stateful installs, vSphere Auto Deploy proceeds as follows:
     - During first boot, vSphere Auto Deploy installs the image on the host.
     - During subsequent boots, the host boots from disk. The hosts do not need a connection to the vSphere Auto Deploy server.
   - For stateless caching, vSphere Auto Deploy proceeds as follows:
     - During first boot, vSphere Auto Deploy provisions the host and caches the image.
     - During subsequent boots, vSphere Auto Deploy provisions the host. If vSphere Auto Deploy is unavailable, the host boots from the cached image, however, setup can only be completed when the host can reach the vSphere Auto Deploy server.

Configure a Host Profile to Use Stateless Caching

If the vSphere Auto Deploy Server is not available, the host uses a cached image and to use stateless caching, you must configure a host profile.

When a host is set up to use stateless caching, if the vSphere Auto Deploy Server is not available, the host uses a cached image. To use stateless caching, you must configure a host profile. You can apply that host profile to other hosts that you want to set up for stateless caching.

> **Important:**
>
> The vSphere Host Profiles capability is deprecated in ESX 9.0 and will be removed in a future release.

- Decide which disk to use for caching and determine whether the caching process will overwrite an existing VMFS partition.

- In production environments, protect the vCenter system and the vSphere Auto Deploy server by including them in a highly available environment. Having the vCenter in a management cluster guarantees that VDS and virtual machine migration are available. If possible, also protect other elements of your infrastructure. See Set Up Highly Available vSphere Auto Deploy Infrastructure.
- Set up your environment for vSphere Auto Deploy. See *Install and Configure vSphere Auto Deploy*.
- Verify that a disk with at least 4GB of free space is available. If the disk is not yet partitioned, partitioning happens when you apply the host profile.
- Set up the host to attempt a network boot first and to boot from disk if network boot fails. See your hardware vendor's documentation.
- Create a host profile. See the *Host Profiles* documentation.

1. Navigate to **Home** > **Policies and Profiles** > **Host Profiles**.
2. Click the host profile you want to configure and select the **Configure** tab.
3. Click **Edit Host Profile**.
4. On the Edit host profile page of the wizard, select **Advanced Configuration Settings** > **System Image Cache Configuration** > **System Image Cache Configuration**.
5. In the **System Image Cache Profile Settings** drop-down menu, choose a policy option.

Option	Description
Enable stateless caching on the host	Caches the image to disk.
Enable stateless caching to a USB disk on the host	Caches the image to a USB disk attached to the host.

6. Depending on the policy option you select, you must do the following:
   a) If you select **Enable stateful installs on the host**:
      1. Specify the information about the disk to use.

Option	Description
Arguments for first disk	When configuring a System Image Install disk, you have multiple options to define the device you want ESX to be installed to and booted from. You can use the following arguments to define the disk for the installation: • `localesx` – The first disk detected containing a valid installation of ESX • `local` – The first local disk detected by ESX after boot • `remoteesx` - The first remote disk detected containing a valid installation of ESX • `sortedremoteesx`- The first remote disk sorted by the lowest LUN ID detected containing a valid installation of ESX • `remote` - The first remote disk detected by ESX after boot • `sortedremote` - The first remote disk sorted by the lowest LUN ID detected by ESX after boot • `device model` • `device vendor` • `vmkernel device driver name` You can get the values for the device model and vendor arguments by running the command `esxcli storage core device list` in a console to the ESX host, logging in as the root. You get the vmkernel device driver name argument by running the command `esxcli storage core adapter list`. You must then identify the storage adapter to which your boot device is connected. By default, the system attempts to replace an existing ESX installation, and then attempts to write to the local disk. You can use the **Arguments for first disk** field to specify a comma-separated list of disks to use, in order of preference. You can specify more than one disk. Use `localesx` for the first disk with ESX installed on it, model and vendor information, or specify the name of the vmkernel device driver. For example, to have the system first look for a disk with the model name ST3120814A, second for any disk that uses the mptsas driver, and third for the local disk, specify `ST3120814A,mptsas,local` as the value of this field. The first disk setting in the host profile specifies the search order for determining which disk to use for the cache. The search order is specified as a comma delimited list of values. The default setting `localesx,local` specifies that vSphere Auto Deploy should first look for an existing local cache disk. The cache disk is identified as a disk with an existing ESX software image. If vSphere Auto Deploy cannot find an existing cache disk, it searches for an available local disk device. When searching for an available disk vSphere Auto Deploy uses the first empty disk that does not have an existing VMFS partition. You can use the first disk argument only to specify the search order. You cannot explicitly specify a disk. For example, you cannot specify a specific LUN on a SAN.
Check to overwrite any VMFS volumes on the selected disk	If you select this check box, the system overwrites existing VMFS volumes if not enough space is available to store the image, image profile, and host profile.
Check to ignore any SSD devices connected to the host	If you select this check box, the system ignores any existing SSD devices and does not store image profiles and host profiles on them.

      2. In the **System Disk Configuration** drop-down menu, select **User must explicitly choose the policy option**.
   b) If you select **Enable stateful installs to a USB disk on the host**:
      1. In the **System Disk Configuration** drop-down menu, select **System disk specified by user in host customization**
      2. Under **Hosts and Clusters**, right-click the host and select **Host Profiles** > **Edit Host Customizations**. Define a disk with persistent storage in the **Value** field for the **System disk** property.

7. Click **Save** to complete the host profile configuration.

Apply the host profile to individual hosts by using the Host Profiles feature in the vSphere Client. See the *Host Profiles* documentation. Alternatively, you can create a rule to assign the host profile to hosts with the vSphere Client or by using VCF PowerCLI. See *Write a Rule and Assign a Host Profile to Hosts*.

- Create a rule that applies the host profile to all hosts that you want to provision with the settings specified in the reference host. For writing a rule in a VCF PowerCLI session, see *Write a Rule and Assign a Host Profile to Hosts*.
- For hosts that are already provisioned with vSphere Auto Deploy, perform the test and repair compliance operations in a VCF PowerCLI session, see *Test and Repair Rule Compliance*.
- Power on unprovisioned hosts to provision them with the new host profile.

Configure a Host Profile to Enable Stateful Installs

To set up an ESX host provisioned with vSphere Auto Deploy to boot from disk, you must configure a host profile.

- Decide which disk to use for storing the image, and determine whether the new image will overwrite an existing VMFS partition.
- Set up your environment for vSphere Auto Deploy. See *Install and Configure vSphere Auto Deploy*.
- Verify that a disk with at least 4GB of free space is available. If the disk is not yet partitioned, partitioning happens when you apply the host profile.
- Set up the host to boot from disk. See your hardware vendor's documentation.
- Create a host profile. See the *Host Profiles* documentation.

You can configure the host profile on a single host. You can also create a host profile on a reference host and apply that host profile to other hosts.

Important:

The vSphere Host Profiles capability is deprecated in ESX 9.0 and will be removed in a future release.

1. Navigate to **Home** > **Policies and Profiles** > **Host Profiles**.
2. Click the host profile you want to configure and select the **Configure** tab.
3. Click **Edit Host Profile**.
4. On the Edit host profile page of the wizard, select **Advanced Configuration Settings** > **System Image Cache Configuration** > **System Image Cache Configuration**.
5. In the **System Image Cache Profile Settings** drop-down menu, choose a policy option.

Option	Description
Enable stateful installs on the host	Caches the image to a disk.
Enable stateful installs to a USB disk on the host	Caches the image to a USB disk attached to the host.

6. Depending on the policy option you select, you must do the following:
   a) If you select **Enable stateful installs on the host**:
      1. Specify the information about the disk to use.

Option	Description
Arguments for first disk	When configuring a System Image Install disk, you have multiple options to define the device you want ESX to be installed to and booted from. You can use the following arguments to define the disk for the installation: • `localesx` – The first disk detected containing a valid installation of ESX • `local` – The first local disk detected by ESX after boot • `remoteesx` - The first remote disk detected containing a valid installation of ESX • `sortedremoteesx`- The first remote disk sorted by the lowest LUN ID detected containing a valid installation of ESX • `remote` - The first remote disk detected by ESX after boot • `sortedremote` - The first remote disk sorted by the lowest LUN ID detected by ESX after boot • `device model` • `device vendor` • `vmkernel device driver name` You can get the values for the device model and vendor arguments by running the command `esxcli storage core device list` in a console to the ESX host, logging in as the root. You get the vmkernel device driver name argument by running the command `esxcli storage core adapter list`. You must then identify the storage adapter to which your boot device is connected. By default, the system attempts to replace an existing ESX installation, and then attempts to write to the local disk. You can use the **Arguments for first disk** field to specify a comma-separated list of disks to use, in order of preference. You can specify more than one disk. Use `localesx` for the first disk with ESX installed on it, model and vendor information, or specify the name of the vmkernel device driver. For example, to have the system first look for a disk with the model name ST3120814A, second for any disk that uses the mptsas driver, and third for the local disk, specify `ST3120814A,mptsas,local` as the value of this field. The first disk setting in the host profile specifies the search order for determining which disk to use for the cache. The search order is specified as a comma delimited list of values. The default setting `localesx,local` specifies that vSphere Auto Deploy should first look for an existing local cache disk. The cache disk is identified as a disk with an existing ESX software image. If vSphere Auto Deploy cannot find an existing cache disk, it searches for an available local disk device. When searching for an available disk vSphere Auto Deploy uses the first empty disk that does not have an existing VMFS partition. You can use the first disk argument only to specify the search order. You cannot explicitly specify a disk. For example, you cannot specify a specific LUN on a SAN.
Check to overwrite any VMFS volumes on the selected disk	If you select this check box, the system overwrites existing VMFS volumes if not enough space is available to store the image, image profile, and host profile.
Check to ignore any SSD devices connected to the host	If you select this check box, the system ignores any existing SSD devices and does not store image profiles and host profiles on them.

      2. In the **System Disk Configuration** drop-down menu, select **User must explicitly choose the policy option**.
   b) If you select **Enable stateful installs to a USB disk on the host**:
      1. In the **System Disk Configuration** drop-down menu, select **System disk specified by user in host customization**
      2. Under **Hosts and Clusters**, right-click the host and select **Host Profiles** > **Edit Host Customizations**. Define a disk with persistent storage in the **Value** field for the **System disk** property.

7. Click **Save** to complete the host profile configuration.

Apply the host profile to individual hosts by using the Host Profiles feature in the vSphere Client. See the *Host Profiles* documentation. Alternatively, you can create a rule to assign the host profile to hosts with the vSphere Client or by using VCF PowerCLI. See *Write a Rule and Assign a Host Profile to Hosts*.

- Create a rule that applies the host profile to all hosts that you want to provision with the settings specified in the reference host. For writing a rule in a VCF PowerCLI session, see *Write a Rule and Assign a Host Profile to Hosts*.
- For hosts that are already provisioned with vSphere Auto Deploy, perform the test and repair compliance operations in a VCF PowerCLI session, see *Test and Repair Rule Compliance*.
- Power on unprovisioned hosts to provision them with the new host profile.

Setting Up a vSphere Auto Deploy Reference Host

In an environment where no state is stored on the ESX host, a reference host helps you set up multiple hosts with the same configuration.

You configure the reference host with the logging, coredump, and other settings that you want, save the host profile, and write a rule that applies the host profile to other hosts as needed. You can configure the storage, networking, and security settings on the reference host and set up services such as syslog and NTP.

Configure an ESX Dump Collector

You can configure an ESX Dump Collector to store core dumps either by using ESXCLI commands or by configuring a reference host.

Hosts provisioned with vSphere Auto Deploy do not have a local disk on which to store core dumps. You can configure an ESX Dump Collector to store core dumps either by using ESXCLI commands or by configuring a reference host to use the ESX Dump Collector by using the Host Profiles feature in the vSphere Client.

Configure ESX Dump Collector with ESXCLI

Hosts provisioned with vSphere Auto Deploy do not have a local disk to store core dumps on. You can configure ESX Dump Collector by using ESXCLI commands and keep core dumps on a network server for use during debugging.

Install ESXCLI if you want to configure the host to use ESX Dump Collector. In troubleshooting situations, you can use ESXCLI in the ESX Shell instead.

A core dump is the state of working memory if there is host failure. By default, a core dump is saved to the local disk. ESX Dump Collector is especially useful for vSphere Auto Deploy, but is supported for any ESX host. ESX Dump Collector supports other customization, including sending core dumps to the local disk and is included with the vCenter management node.

> **Note:**
> ESX Dump Collector is not supported to be configured on a VMkernel interface that is running on a NSX-T N-VDS switch.

If you intend to use IPv6, and if both the ESX host and ESX Dump Collector are on the same local link, both can use either local link scope IPv6 addresses or global scope IPv6 addresses.

If you intend to use IPv6, and if ESX and ESX Dump Collector are on different hosts, both require global scope IPv6 addresses. The traffic routes through the default IPv6 gateway.

1. Set up an ESX system to use ESX Dump Collector by running `esxcli system coredump` in the local ESX Shell or by using ESXCLI.

   ```
   esxcli system coredump network set --interface-name vmk0 --server-ip 10xx.xx.xx.xx --server-port 6500
   ```

   You must specify a VMkernel NIC and the IP address and optional port of the server to send the core dumps to. You can use an IPv4 address or an IPv6 address. If you configure an ESX system that is running on a virtual machine that is using a vSphere standard switch, you must select a VMkernel port that is in promiscuous mode.

2. Enable ESX Dump Collector.
   ```
   esxcli system coredump network set --enable true
   ```
3. Optional: Verify that ESX Dump Collector is configured correctly.
   ```
   esxcli system coredump network check
   ```

The host on which you have set up ESX Dump Collector is configured to send core dumps to the specified server by using the specified VMkernel NIC and optional port.

- Create a rule that applies the host profile to all hosts that you want to provision with the settings specified in the reference host. For writing a rule in a VCF PowerCLI session, see *Write a Rule and Assign a Host Profile to Hosts*.
- For hosts that are already provisioned with vSphere Auto Deploy, perform the test and repair compliance operations in a VCF PowerCLI session, see *Test and Repair Rule Compliance*.
- Power on unprovisioned hosts to provision them with the new host profile.

Configure ESX Dump Collector from the Host Profiles Feature in the vSphere Client

Hosts provisioned with vSphere Auto Deploy do not have a local disk to store core dumps on. You can configure a reference host to use ESX Dump Collector by using the Host Profiles feature in the vSphere Client.

- Verify that you have created the host profile on which you want to configure a coredump policy. For more information on how to create a host profile, see the *vSphere Host Profiles* documentation.
- Verify that at least one partition has sufficient storage capability for core dumps from multiple hosts provisioned with vSphere Auto Deploy.

Best practice is to set up hosts to use ESX Dump Collector with the `esxcli system coredump` command and save the host profile. For more information, see Configure ESX Dump Collector with ESXCLI.

1. Navigate to **Home** > **Policies and Profiles** > **Host Profiles**.
2. Click the host profile you want to configure and select the **Configure** tab.
3. Click **Edit Host Profile**.
4. Select **Networking Configuration** > **Network Coredump Settings**.
5. Select the **Enabled** check box.
6. Specify the host NIC to use, the Network Coredump Server IP, and the Network Coredump Server Port.
7. Click **Save** to complete the host profile configuration.

- Create a rule that applies the host profile to all hosts that you want to provision with the settings specified in the reference host. For writing a rule in a VCF PowerCLI session, see *Write a Rule and Assign a Host Profile to Hosts*.
- For hosts that are already provisioned with vSphere Auto Deploy, perform the test and repair compliance operations in a VCF PowerCLI session, see *Test and Repair Rule Compliance*.
- Power on unprovisioned hosts to provision them with the new host profile.

Configure Syslog from Host Profiles in the vSphere Client

Specify a remote syslog server by applying a host profile.

Hosts provisioned with vSphere Auto Deploy usually do not have sufficient local storage to save system logs. You can specify a remote syslog server for those hosts by setting up a reference host, saving the host profile, and applying that host profile to other hosts as needed.

- If you intend to use a remote syslog host, set up that host before you customize host profiles.
- Verify that you have access to the vSphere Client and the vCenter system.

Best practice is to set up the syslog server on the reference host with the vSphere Client or the `esxcli system syslog` command and to save the host profile. You can also set up syslog from the Host Profiles feature in the vSphere Client.

1. Navigate to **Home** > **Policies and Profiles** > **Host Profiles**.
2. Optional: If no reference host exists in your environment, click **Extract Profile from Host** to create a host profile.
3. Click the host profile you want to configure and select the **Configure** tab.
4. Click **Edit Host Profile**.
5. Select **Advanced Configuration Settings** > **Advanced Options** > **Advanced configuration options**.
   You can select specific sub-profiles and edit the syslog settings.
6. Optional: To create an advanced configuration option.
   a) Click the **Add sub-profile** icon.
   b) From the **Advanced option** drop-down list select **Configure a fixed option**.
   c) Specify *Syslog.global.loghost* as the name of the option, and your host as the value of the option.
7. Click **Save** to complete the host profile configuration.

- Create a rule that applies the host profile to all hosts that you want to provision with the settings specified in the reference host. For writing a rule in a VCF PowerCLI session, see *Write a Rule and Assign a Host Profile to Hosts*.
- For hosts that are already provisioned with vSphere Auto Deploy, perform the test and repair compliance operations in a VCF PowerCLI session, see *Test and Repair Rule Compliance*.
- Power on unprovisioned hosts to provision them with the new host profile.

Enable NTP Client on a Reference Host in the vSphere Client

When you collect logging information in large environments, you must ensure that log times are coordinated.

You can set up the reference host to use the NTP server in your environment, extract the host profile and create a vSphere Auto Deploy rule to apply it to other hosts.

1. Navigate to **Home** > **Hosts and Clusters**, and select an ESX host that you want to use as a reference host.
2. Select the **Configure** tab.
3. Under **System**, select **Time Configuration**.
4. Select the **Use Network Time Protocol** radio button.
   This option synchronizes the time and date of the host with an NTP server. The NTP service on the host periodically takes the time and date from the NTP server.
5. From the **NTP Service Startup Policy** drop-down menu, select **Start and stop with host**.
6. In the **NTP Servers** text box, enter the IP addresses or host names of the NTP servers that you want to use.
7. Click **OK**.

- Extract a host profile from the reference host. See the *Host Profiles* documentation.
- Create a rule that applies the host profile to all hosts that you want to provision with the settings specified in the reference host. For writing a rule in a VCF PowerCLI session, see *Write a Rule and Assign a Host Profile to Hosts*.

Configure Networking for Your vSphere Auto Deploy Host in the vSphere Client

You can set up networking for your vSphere Auto Deploy reference host and apply the host profile to all other hosts to guarantee a fully functional networking environment.

Provision the host you want to use as your reference host with an ESX image by using vSphere Auto Deploy.

1. Navigate to **Home** > **Hosts and Clusters**, and select an ESX host that you want to use as a reference host.
2. Select the **Configure** tab and navigate to **Networking**.
3. Perform the networking setup.
   If you are using virtual switches and not vSphere Distributed Switch, do not add other VMkernel NICs to vSwitch0.

4. After the reference host is configured, reboot the system to verify that vmk0 is connected to the Management Network.
5. If no host profile exists for your reference host, create a host profile.

- Create a rule that applies the host profile to all hosts that you want to provision with the settings specified in the reference host. For writing a rule in a VCF PowerCLI session, see *Write a Rule and Assign a Host Profile to Hosts*.
- For hosts that are already provisioned with vSphere Auto Deploy, perform the test and repair compliance operations in a VCF PowerCLI session, see *Test and Repair Rule Compliance*.
- Power on unprovisioned hosts to provision them with the new host profile.

Configure a Reference Host for Auto-Partitioning

You can create a reference host to auto-partition all host you provision with vSphere Auto Deploy.

By default, vSphere Auto Deploy provisions hosts only if a partition is available on the host. The auto-partitioning option creates a VMFS datastore on your host's local storage. You can set up a reference host to auto-partition all hosts that you provision with vSphere Auto Deploy.

- Provision the host that you want to use as your reference host with an ESX image by using vSphere Auto Deploy.
- Verify that you have access to a vSphere Client that can connect to the vCenter system.

> **CAUTION:**
> If you change the default auto-partitioning behavior, vSphere Auto Deploy overwrites existing partitions regardless of their content. If you turn on this option, ensure that no unintended data loss results.
>
> To ensure that local SSDs remain unpartitioned during auto-partitioning, you must set the parameter `skipPartitioningSsds=TRUE` on the reference host.
>
> For more information about preventing SSD formatting during auto-partitioning, see the *vSphere Storage* documentation.

1. Navigate to **Home** > **Hosts and Clusters**, and select an ESX host that you want to use as a reference host.
2. Select the **Configure** tab.
3. Under **System**, select **Advanced System Settings** and click **Edit**.
4. Search for the `VMkernel.Boot.autoPartition` key and set the value to **true**.
5. Optional: If you want the local SSDs to remain unpartitioned, search for the `VMkernel.Boot.skipPartitioningSsds` key and set the value to **true**.
6. Click **OK**.
7. If no host profile exists for your reference host, create a host profile.

Auto-partitioning is performed when the hosts boot.

- Use vSphere Auto Deploy to create a rule that applies the host profile of your reference host to all hosts immediately when they boot. To create a rule with the vSphere Client, see Create a Deploy Rule. For writing a rule in a VCF PowerCLI session, see Write a Rule and Assign a Host Profile to Hosts.

Converting Stateless Hosts to Stateful Hosts

You can add physical storage to your stateless ESX, convert them to stateful ESX hosts, and add the hosts to a cluster that you manage by an image.

Your ESX hosts must have physical storage attached, because a cluster managed by an image does not support stateless ESX hosts, that use a Preboot Execution Environment (PXE) boot.

To ensure that image components are installed on a physical disk of an ESX host during a boot process, Auto Deploy verifies that a host profile is part of the PXE boot image. The host profile must contain a "System Image Cache Profile Settings" policy with configuration set to "Enable stateful installs on the host" or "Enable stateful installs to a USB disk on the host". If the attached host profile does not contain this policy or the policy's configuration differs, then the policy is

automatically configured to support a stateful installation. If a host profile is missing, a new host profile is attached to the cluster, containing only the "System Image Cache Profile Settings" policy with a configuration for a stateful installation.

Convert a Diskless ESX Host

To add diskless ESX hosts to a cluster managed by an image, add physical storage, convert them to stateful hosts and install an ESX 9.0 image.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy* in the *VMware ESX Installation and Setup* documentation.
- The ESX host is booting from an Auto Deploy rule that contains an Image Profile.
- The Auto Deploy service is running.
- You have an empty USB stick or other supported storage.

For information on stateless caching and stateful installs, see Use vSphere Auto Deploy for Stateless Caching and Stateful Installs.

1. From the home menu, click **Policies and Profiles**, and select **Host Profiles**.
2. Extract a host profile from a running ESX host or duplicate an existing host profile with a specified configuration and a host location.

   The existing host profile can be attached either to a host or to a cluster.
3. Right-click the new host profile, select **Edit Host Profile**, and browse to **Advanced Configuration Settings** > **System Image Cache Configuration** > **System Image Cache Configuration**.
4. In the **System Image Cache Profile Settings** drop-down menu, choose a policy option.

Option	Description
Enable stateless caching on the host	Caches the image to disk.
Enable stateless caching to a USB disk on the host	Caches the image to a USB disk attached to the host.

5. Depending on the policy option you select, you must do the following:
   a) If you select **Enable stateless caching on the host**:
      1. Enter arguments for the first disk, and select the check boxes if needed.
      2. In the **System Disk Configuration** drop-down menu, select **User must explicitly choose the policy option**.

   b) If you select **Enable stateless caching to a USB disk on the host**:
      1. In the **System Disk Configuration** drop-down menu, select **System disk specified by user in host customization**
      2. Under **Hosts and Clusters**, right-click the host and select **Host Profiles** > **Edit Host Customizations**. Define a disk with persistent storage in the **Value** field for the **System disk** property.
6. Click **Save** to complete the host profile configuration.
7. If you duplicated an existing host profile and the host profile was attached to a cluster, attach the new host profile to the cluster.
8. From the home menu, click **Auto Deploy**.
9. Deactivate the Auto Deploy rule that contains an Image Profile, and click **Edit**.

   The Edit Deploy Rule dialog box appears.
10. On the **Select image profile** page of the wizard, select an ESX 8.0 image profile.
11. On the **Select host profile** page of the wizard, select the new host profile.
12. Activate the rule and move the rule to the rule's initial position in the ordered list.
13. On the **Deployed Hosts** tab, select a single or multiple ESX hosts.
14. Click **Remediate Host Associations** for the ESX host.

    You can monitor the progress of the remediation process in the Recent Tasks pane.

15. Shut down the remediated ESX hosts.
16. After the ESX hosts are powered off, install the selected storage as local boot disks.
17. Power on each ESX host, enter the BIOS/UEFI setup, and change the boot order to boot first from the newly added storage and then from the network.

    Since the newly added storage is empty, each ESX host boots from the network and installs the ESX 9.1 image that you specified earlier on the storage. After the installation, each ESX host reboots and boots from the newly added storage.

The ESX hosts boot by default from the new storage and operate as if the ESX9.1 image is installed from a standard DVD.

Add the ESX hosts to a cluster that you manage by a single image. For more information, see *Add a Host* from the *vCenter and Host Management* documentation.

Convert a Stateless ESX Host with Enabled Stateless Caching

To add your stateless ESX hosts to a cluster that you manage by an image, convert them to stateful hosts by installing a standard 9.1 image.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy* in the *VMware ESX Installation and Setup* documentation.
- The ESX host is booting from an Auto Deploy rule that contains an Image Profile.
- The Auto Deploy service is running.

For information on stateless caching and stateful installs, see Use vSphere Auto Deploy for Stateless Caching and Stateful Installs.

1. From the home menu, click **Policies and Profiles**, and select **Host Profiles**.
2. Extract a host profile from a running ESX host or duplicate an existing host profile with a specified configuration and a host location.

   The existing host profile can be attached either to a host or to a cluster.
3. Right-click the new host profile, select **Edit Host Profile**, and browse to **Advanced Configuration Settings** > **System Image Cache Configuration** > **System Image Cache Configuration**.
4. Select **Enable stateful installs on the host** from the drop-down menu, enter `local` in the **Arguments for first disk** text box, and select the **Check to overwrite any VMFS volumes on the selected disk** check box.
5. If you duplicated an existing host profile and the host profile was attached to a cluster, attach the new host profile to the cluster.
6. From the home menu, click **Auto Deploy**.
7. Deactivate the Auto Deploy rule that contains an Image Profile, and click **Edit**.

   The Edit Deploy Rule dialog box appears.
8. On the **Select image profile** page of the wizard, select an ESX 8.0 image profile.
9. On the **Select host profile** page of the wizard, select the new host profile.
10. Activate the rule and move the rule to the rule's initial position in the ordered list.
11. On the **Deployed Hosts** tab, select a single or multiple ESX hosts.
12. Click **Remediate Host Associations** for the ESX host.

    You can monitor the progress of the remediation process in the Recent Tasks pane.
13. Restart the ESX hosts.

    If an ESX host has a legacy BIOS, you can change the boot order in the BIOS setup to first to boot from the local storage. For UEFI-based ESX hosts the boot order changes automatically during the reboot.

    Each ESX host boots from the network and installs the ESX9.1 image that you specified earlier on the storage used previously for caching. After the installation, each ESX host reboots again and boots from the local storage.

The ESX hosts boot by default from the new storage and operate as if the ESX9.1 image is installed from a standard DVD.

Add the ESX hosts to a cluster that you manage by a single image. For more information, see *Add a Host* from the *vCenter and Host Management* documentation.

Convert a Stateless ESX Host with a Single VMFS Partition on the Local Disk

To add your stateless ESX hosts to a cluster that you manage by an image, you must first convert the hosts to stateful hosts by repartitioning the VMFS partitions and installing a standard ESX 9.1 image.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy* in the *VMware ESX Installation and Setup* documentation.
- The ESX host is booting from an Auto Deploy rule that contains an Image Profile.
- The Auto Deploy service is running.

For information on stateless caching and stateful installs, see Use vSphere Auto Deploy for Stateless Caching and Stateful Installs.

1. From the home menu, click **Policies and Profiles**, and select **Host Profiles**.
2. Extract a host profile from a running ESX host or duplicate an existing host profile with a specified configuration and a host location.

   The existing host profile can be attached either to a host or to a cluster.
3. Right-click the new host profile, select **Edit Host Profile**, and browse to **Advanced Configuration Settings** > **System Image Cache Configuration** > **System Image Cache Configuration**.
4. Select **Enable stateful installs on the host** from the drop-down menu, enter `localesx` in the **Arguments for first disk** text box.
5. If you duplicated an existing host profile and the host profile was attached to a cluster, attach the new host profile to the cluster.
6. From the home menu, click **Auto Deploy**.
7. Deactivate the Auto Deploy rule that contains an Image Profile, and click **Edit**.

   The Edit Deploy Rule dialog box appears.
8. On the **Select image profile** page of the wizard, select an ESX 8.0 image profile.
9. On the **Select host profile** page of the wizard, select the new host profile.
10. Activate the rule and move the rule to the rule's initial position in the ordered list.
11. On the **Deployed Hosts** tab, select a single or multiple ESX hosts.
12. Click **Remediate Host Associations** for the ESX host.

    You can monitor the progress of the remediation process in the Recent Tasks pane.
13. Restart the ESX hosts.

    If an ESX host has a legacy BIOS, you can change the boot order in the BIOS setup to first to boot from the local storage. For UEFI-based ESX hosts the boot order changes automatically during the reboot.

    Each ESX host boots from the network, repartitions the VMFS partition to a standard ESX installation partition, and installs the ESX9.1 image that you specified earlier on the partition. After the installation, each ESX host reboots again and boots from the standard ESX partition.

The ESX hosts boot by default from the new partition and operate as if the ESX9.1 image is installed from a standard DVD.

Add the ESX hosts to a cluster that you manage by a single image. For more information, see *Add a Host* from the *vCenter and Host Management* documentation.

Convert a Stateless ESX Host with a Single VMFS Partition on a Remote Disk

To add your stateless ESX hosts to a cluster that you manage by an image, first you must convert the hosts to stateful hosts by repartitioning their remote VMFS partitions and installing a standard ESX9.1 image. For example, your ESX host can boot from Fibre Channel SAN or from iSCSI SAN.

- Prepare your system and install the Auto Deploy Server. For more information, see *Prepare Your System for vSphere Auto Deploy* in the *VMware ESX Installation and Setup* documentation.
- The ESX host is booting from an Auto Deploy rule that contains an Image Profile.
- The Auto Deploy service is running.

For information on stateless caching and stateful installs, see Use vSphere Auto Deploy for Stateless Caching and Stateful Installs.

For more information on booting from a remote disk, see the *Booting from iSCSI SAN* in the *vSphere Storage* documentation.

1. From the home menu, click **Policies and Profiles**, and select **Host Profiles**.
2. Extract a host profile from a running ESX host or duplicate an existing host profile with a specified configuration and a host location.

   The existing host profile can be attached either to a host or to a cluster.
3. Right-click the new host profile, select **Edit Host Profile**, and browse to **Advanced Configuration Settings** > **System Image Cache Configuration** > **System Image Cache Configuration**.
4. Select **Enable stateful installs on the host** from the drop-down menu, enter `remoteesx,remote` or `sortedremoteesx,sortedremote` in the **Arguments for first disk** text box.
5. If you duplicated an existing host profile and the host profile was attached to a cluster, attach the new host profile to the cluster.
6. From the home menu, click **Auto Deploy**.
7. Deactivate the Auto Deploy rule that contains an Image Profile, and click **Edit**.

   The Edit Deploy Rule dialog box appears.
8. On the **Select image profile** page of the wizard, select an ESX 8.0 image profile.
9. On the **Select host profile** page of the wizard, select the new host profile.
10. Activate the rule and move the rule to the rule's initial position in the ordered list.
11. On the **Deployed Hosts** tab, select a single or multiple ESX hosts.
12. Click **Remediate Host Associations** for the ESX host.

    You can monitor the progress of the remediation process in the Recent Tasks pane.
13. Restart the ESX hosts.

    Each ESX host boots from the network, repartitions the VMFS partition to a standard ESX installation partition, and installs the ESX9.1 image that you specified earlier on the partition. After the installation, each ESX host reboots again and boots from the remote standard ESX partition.

The ESX hosts boot by default from the new partition and operate as if the ESX9.1 image is installed from a standard DVD.

Add the ESX hosts to a cluster that you manage by a single image. For more information, see *Add a Host* from the *vCenter and Host Management* documentation.

Using Zero Touch Provisioning

With Zero Touch Provisioning, also called vSphere Elastic Provisioning, you can install ESX on hosts at scale from a single UEFI HTTPS boot URL or a static network configuration on bare metal.

In this chapter, see:

- What is Zero Touch Provisioning with Auto Deploy
- How to Choose and Switch Between Provisioning Methods in Auto Deploy
- Image ESX Hosts by Network with a UEFI HTTPS Boot URL Configured Directly in the UEFI Firmware
- How to Provision a Heterogeneous Cluster with Zero Touch Provisioning
- How to Provision ESX Hosts in Heterogeneous Clusters with the Auto Deploy - stateless Method
- How Zero Touch Provisioning Works with vSphere Configuration Profiles

What is Zero Touch Provisioning with Auto Deploy

Zero Touch Provisioning combines a vCenter-level UEFI HTTPS boot URL and a UEFI HTTPS boot facility to enable ESX provisioning at scale.

UEFI firmware and UEFI HTTPS boot allow you to avoid configuring PXE infrastructure and using network services such as TFTP, DHCP, and DHCP relay agents in complicated network configurations.

Starting with VCF 9.1, the management of UEFI HTTPS Boot moves from Auto Deploy to the Zero Touch Provisioning capability. The Boot Routing Service (BRS), which is part of Zero Touch Provisioning and is managed by the vSphere Lifecycle Manager, now serves the UEFI HTTPS boot URL. However, BRS does not have its own rule engine and depends on the Auto Deploy rule matching functionality, so Zero Touch Provisioning and Auto Deploy work together for UEFI HTTPS Boot scenarios.

Along wth BRS, Zero Touch Provisioning also adds a new first-stage bootloader, vSphere Boot Manager (vBM), replacing the iPXE bootloader used by Auto Deploy, and the Network Boot Service (NBS), which allows provisioning ESX hosts over the network.

Zero Touch Provisioning also introduces support for heterogeneous clusters that are managed by the vSphere Lifecycle Manager, provisioning multiple ESX images in a single cluster, including clusters using a vSphere Configuration Profile.

In the Zero Touch Provisioning scenarios, ESX hosts are provisioned directly from an HTTPS boot URL that is exposed by BRS and served by NBS.

You can use the Zero Touch Provisioning method to provision ESX hosts with all versions starting from ESXi 8.0 Update 3.

> **Note:**
>
> Network booting adds support to the common port 443 along with port 6501 that is used for iPXE boot in existing environments.

With Zero Touch Provisioning, you can:

- Use the UEFI HTTPS boot protocol to image ESX hosts at scale by using a single boot URL.
- Use a single boot URL on vCenter level for imaging devices from different hardware vendors to clusters with many alternative images based on hardware information such as SMBIOS data.
- Image ESX hosts over the network without DHCP and TFTP servers, using only static network configuration with UEFI HTTPS boot URL configured directly in the UEFI firmware.

Table 23: Comparison of the Auto Deploy and Zero Touch Provisioning operational components

Classic Auto Deploy (legacy)	Zero Touch Provisioning
• iPXE bootloader • TFTP server required • Per-host DHCP config (must have) • PXE infrastructure	• vSphere Boot Manager (vBM) • Single HTTPS URL for all hosts • Per-host DHCP config (optional) • BRS + NBS in vSphere Lifecycle Manager

Zero Touch Provisioning depends on the existence of HTTPS boot support in the underlying hardware.

You have the following options for setting the boot URL when performing an HTTPS boot, depending on the firmware capabilities:

- using a DHCP server to serve the boot URL as part of the network configuration
- using a management console such as iDRAC or inventory management tools
- interacting with the firmware setup/boot menu through the device console

For the HTTPS boot to work, ESX hosts must trust the vCenter certificate, which means that you must upload a vCenter certificate on the server. For more information, see Image ESX Hosts by Network with a UEFI HTTPS Boot URL Configured Directly in the UEFI Firmware.

Boot Routing Service

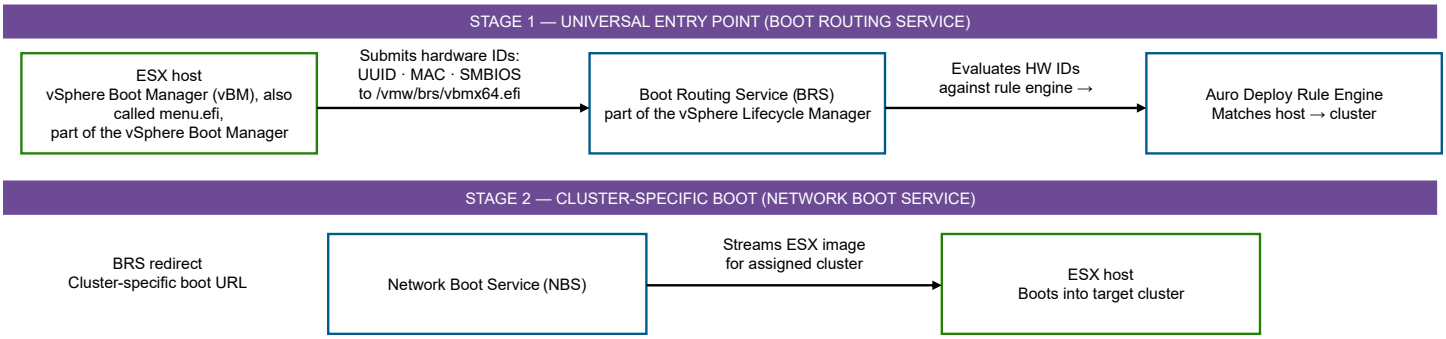
BRS exposes a single vCenter-level HTTPS boot URL, `https://<vcenter-ip/fqdn>/vmw/brs/vbmx64.efi`, that is configured once — either in a DHCP server, UEFI firmware, or management console — and applies to all physical machines managed by the vCenter instance. When an ESX host boots, vBM (menu.efi) submits hardware identifiers such as UUID, MAC address, and SMBIOS data to BRS. BRS evaluates these identifiers against the Auto Deploy Rule engine and issues a redirect to the appropriate cluster boot URL.

Network Boot Service

NBS serves cluster-specific Network Bootbanks (NBF) over HTTPS, eliminating the dependency on legacy PXE/TFTP infrastructure. ESX boot images and configurations are prepared in advance, stored on the vCenter filesystem, and exposed by cluster-scoped URLs (`/vmw/nbs/clusters/<cluster-id>/`).

BRS and NBS implement a two-stage network boot pipeline. BRS operates as the universal entry point: a single boot URL serves all devices managed by a vCenter instance, regardless of the intended destination in its inventory. NBS provides the cluster-specific boot. streaming ESX images for the assigned cluster. Both services are part of the vSphere Lifecycle Manager.

Figure 9: BRS + NBS Two-Stage Boot Pipeline



Upon receiving a boot request, BRS collects hardware attributes by vBM and consults the Auto Deploy Rule engine to determine the target cluster. BRS then redirects the booting host to the cluster-specific boot URL served by NBS. For stateless deployments, BRS redirects to an Auto Deploy-derived boot URL instead of an NBS cluster URL, preserving full backward compatibility with existing Auto Deploy rule sets.

In the Auto Deploy screen, when you select Zero Touch Provisioning as provisioning method, you see two tasks running in the **Recent Tasks** panel:

1. **Enable network boot**, which changes the network configuration of the cluster.
2. **Create network bootbank**, during which the vSphere Lifecycle Manager downloads VIBs from an online depot to a network bootbank, from which ESX hosts are booting.

For Zero Touch Provisioning, you only need the host location to identify the cluster to deploy the rule. The rule uses the image that has been created during the **Create network bootbank** task and the configuration of the cluster.

How to Choose and Switch Between Provisioning Methods in Auto Deploy

With ESX 9.1 and later, you can choose and switch between three methods to provision ESX hosts at scale by using Auto Deploy rules.

Starting with ESX 9.1, you can choose between Zero Touch Provisioning, Auto Deploy - stateful, and Auto Deploy - stateless options to provision ESX hosts at scale, depending on your needs. The **Clusters** tab under Auto Deploy in the vSphere Client adds a column **Provisioning Method**, which tracks your selections.

Note:

In the **Lifecycle Management Method** column, you might see the value **Baselines** for clusters that are not updated to VCF 9.0 and later, and neither of the **Provisioning Method** options works. If your environment has clusters that are managed by using legacy baselines, the **Provisioning Method** column is blank. You cannot create new such clusters, but the existing ones remain active and you can add Auto Deploy rules to them. You cannot change their provisioning method before you update to VCF 9.0 and later.

If an ESX host does not match any of the existing rules, you see it listed under the **Discovered Hosts** tab.

For a new empty cluster, you can select between:

- Auto Deploy - stateful, which defaults to provisioning ESX by using a vSphere Lifecycle Manager image stored on the device.
- Zero Touch Provisioning, which can use desired images, a vSphere Configuration Profile, or simply a cluster. Zero Touch Provisioning is not supported on folder level.
- Auto Deploy - stateless to select provisioning that does not cache the ESX image.

All images, except for stateless, which uses Auto Deploy images, are managed by the vSphere Lifecycle Manager. You can manage cluster configuration by either vSphere Configuration Profiles or vSphere Host Profiles, which are deprecated.

Table 24: Transitions between provisioning methods

Provisioning Method	Cluster Empty or Not	Transition to Auto Deploy - stateful	Transition to Auto Deploy - stateless	Transition to Zero Touch Provisioning
Auto Deploy - stateful	Empty cluster	N/A	Allowed	Allowed
Auto Deploy - stateful	Cluster with hosts	N/A	Not allowed	Allowed
Auto Deploy - stateless	Empty cluster	Allowed	N/A	Allowed
Auto Deploy - stateless	Cluster with hosts	Not allowed	N/A	Not allowed
Zero Touch Provisioning	Empty cluster	Allowed	Not allowed	N/A
Zero Touch Provisioning	Cluster with hosts	Allowed	Not allowed	N/A

If a stateful Host Profile is attached to the cluster or if a vSphere Configuration Profile is enabled on the cluster, you cannot transition clusters from stateful to stateless.

When creating a cluster in vCenter, it defaults to the provisioning method Auto Deploy - stateful. This means that when you create a rule for this cluster, Auto Deploy automatically picks up a vSphere Lifecycle Manager image for this cluster. ESX hosts added to such cluster are provisioned with that image by using the PXE infrastructure. Since the image is locally stored on the ESX hosts, this provisioning method is known as stateful installation. The Auto Deploy - stateful method does not support provisioning of heterogeneous, or composite, clusters.

From the default Auto Deploy - stateful method, you can switch to Zero Touch Provisioning by selecting **Enable Zero Touch Provisioning**, which is also a stateful installation method. Zero Touch Provisioning rules use the BRS and NBS services instead of the PXE infrastructure, as long as the firmware provides HTTP boot support. For servers that use BIOS, you cannot use the Zero Touch Provisioning method. With Zero Touch Provisioning, you can provision both homogeneous and heterogeneous clusters, because this provisioning method works for both.

Reverting the method from Zero Touch Provisioning to Auto Deploy - stateful excludes support for provisioning heterogeneous clusters and deletes the network bootbank that is created for this cluster. In such a case, all existing rules that are tied to that cluster deactivate and you need either to edit the existing or create new rules.

You can also switch an empty cluster to Auto Deploy - stateless by selecting **Enable AutoDeploy Stateless Support**, which means that no image is locally stored on ESX hosts in this cluster.

For empty clusters, you can revert from the Zero Touch Provisioning to the Auto Deploy - stateful or Auto Deploy - stateless method.

> **Note:**
>
> When you select Zero Touch Provisioning, you can track progress in the **Recent Tasks** panel, represented as tasks. The tasks are: Create Network Bootbank, Delete Network Bootbank, Deduplicate Network Bootbank, and Host Network Boot Progress. If the tasks are not complete and you create a rule, the rule restores the default stateful install option, because it cannot find a network bootbank.

After you create a rule for Zero Touch Provisioning, if you switch the rule to Auto Deploy - stateful, the rule automatically updates and changes the bootbank. Except when you are using a heterogeneous cluster, then the rule is deactivated.

When reverting the method from Zero Touch Provisioning to Auto Deploy - stateless, you manage the lifecycle of hosts part of stateless clusters or standalone hosts only by using Auto Deploy. vSphere Lifecycle Manager operations relevant to stateful hosts such as single image association, image compliance, and remediation, are not supported for stateless clusters.

Image ESX Hosts by Network with a UEFI HTTPS Boot URL Configured Directly in the UEFI Firmware

With UEFI HTTPS network boot support, you can provision ESX hosts by using a static network configuration with the boot URL configured directly in the firmware.

Even without a TFTP server, the DHCP server returns the IP and a boot URL required for network booting. You can use these parameters to set a static network configuration with the boot URL configured directly in the firmware, also called bare metal provisioning. You can manually modify the configuration parameters in the firmware to a UEFI HTTPS boot URL. You can set such a URL as a static value in the configuration of any server that supports UEFI HTTPS.

When you activate Zero Touch Provisioning on a cluster, in the **Zero Touch Provisioning** table at **Auto Deploy** > **Configure**, you can find the UEFI HTTPS Boot URL, such as `https://<vcenter-ip/fqdn>/vmw/brs/bootx64.efi`, which you can use to create a static network configuration directly in the UEFI firmware and not depend on a DHCP server.

If you use iDRAC to log in to a Dell server, under **Configuration** > **BIOS Settings** > **Network Settings**, you should disable all PXE devices and enable an HTTP device with the following settings:

- Deactivate DHCP,
- Set the static IP address or VLAN, subnet mask, gateway, and DNS servers,
- in the URI field, paste the HTTP(S) boot url that you copy from the **Zero Touch Provisioning** table at **Auto Deploy** > **Configure**.

> **Note:**
>
> Starting with VCF 9.1, you can use the common port 443 for network booting along with port 6501. Both IPv4 and IPv6 are supported.

Alternatively, you can paste the HTTPS boot URL in the DHCP configuration.

For the HTTPS boot to work, ESX hosts must trust the vCenter certificate, which means that you must upload a vCenter certificate on the server.

To export the security certificate from the vCenter instance, see Download and Install the vCenter Certificate. When you extract the zip package, open the `win` folder and see the certificate with extension `.0.crt`. To convert the certificate in the recommended Distinguished Encoding Rules (DER) format, use the command `openssl x509 -outform der -in <certificate file name>.crt -out <certificate file name>.der`.

You can use alternative ways to get vCenter certificates but use only the vCenter CA certificate.

When uploading the vCenter certificate, the server interface might differ per vendor. In Dell iDRAC, for example, you must upload the file that you export in DER format in **Root Certification Configuration**.

When setting the UEFI HTTPS boot URL as a static value in a server configuration, you must set the **TLS Authentication Mode** under **TLS Authentication Configuration** to One Way.

If the downgrade support on your firmware is active, you can use Zero Touch Provisioning with TLS 1.1, TLS 1.2, and TLS 1.3.

VCF 9.0 and later supports TLS 1.3, but if your servers do not support this version, you must explore other configuration options for your environment. For example, you can set up a secure server for TLS 1.3 only, and can use another server for ESX host provisioning that uses TLS 1.2.

How to Provision a Heterogeneous Cluster with Zero Touch Provisioning

With Zero Touch Provisioning, you can provision custom images of ESX to hosts in one cluster, depending on different criteria.

With Zero Touch Provisioning, you can boot different devices with custom images, which are based on criteria such as hardware information, in heterogeneous clusters.

The following steps cover a possible end-to-end scenario where you provision ESX hosts in a cluster with a default image and an OEM vendor add-on image. Provisioning with the add-on image depends on the underlying hardware.

Before you begin, make sure that you have a default ESX image and an OEM vendor add-on image in an online or offline depot. For more information, see Add a Software Depot or Import a Software Depot.

- In the vSphere Client, create a datacenter and a cluster with a heterogenous software specification that contains a default image and an OEM vendor add-on image:
  - In the **Basics** tab of the **New Cluster** workflow, select **Create a new image** and **Manage configuration at a cluster level** to allow the use of vSphere Configuration Profiles.
  - In the **Image** tab, select a default ESX version and a vendor add-on image.

    A heterogeneous cluster is created.
- In the cluster, click **Updates** > **Image** > **Edit** to add the vendor add-on image to the default one and check the **Select hosts by host's hardware criteria** option, specifying the vendor name.

  This selection defines that only servers from the respective OEM vendor get the custom add-on image. All other servers in the cluster get the default desired image for the cluster.
- In the **Auto Deploy** tab, select the **Enable Zero Touch Provisioning** option to activate UEFI HTTPS network boot support.

  In the **Recent Tasks** panel, you see two tasks appearing: **Enable network boot task on the cluster** and **Create network bootbank task**. Wait until both tasks are completed.

  When the **Create network bootbank** task completes, you see a boot URL configured in the **Target** field. The boot URL cannot work without the Auto Deploy rule engine, which redirects the booting host to the network boot folder corresponding to the target cluster.
- Create a Deploy Rule in Auto Deploy.

  All hosts that try to boot from the network boot URL are redirected to boot from the network bootbank generated for this cluster.
  - In **Name and hosts**, select **All hosts**.
  - In **Configuration**, select only **Host location**.
  - In **Select host location**, select the cluster.

    Any host on this cluster is going to use the network bootbank generated for this cluster.
  - Activate the rule.
- Monitor provisioning:

  Starting with VCF 9.1, you can use remote consoles for each host to monitor the provisioning. Imaging ESX hosts by Zero Touch Provisioning provides new output from the new boot logger service, vSphere Boot Manager (vBM).

  vBM extracts the SMBIOS data from virtual machines, sends it back to the boot routing service (BRS) and the boot routing service translates the SMBIOS data to Auto Deploy. Auto Deploy then matches the host against the rule that you have created. For example, hosts that are based on Dell servers can boot with an add-on from the vendor, while other hosts boot with the desired image for the cluster. The ESX installer downloads over the network. The installation completes automatically. Once the installation is complete, hosts reboot from the local disk, the desired configuration is applied, and they are added to the target cluster in vCenter.
- Confirm image compliance:
  - Go to the **Image Compliance** panel under the **Updates** tab and click **Check Compliance** to confirm that the correct desired images are selected for the correct virtual machines.

– Go to **Configure tab** > **Desired State** > **Configuration** and click **Check Compliance** to confirm the configuration.

How to Provision ESX Hosts in Heterogeneous Clusters with the Auto Deploy - stateless Method

You can provision ESX hosts in a single cluster with different images by using the Auto Deploy - stateless method and separate rules for each image.

Add or import at least two online or offline depots in the **Software Depots** tab of the Auto Deploy screen. See Add a Software Depot or Import a Software Depot.

Selecting the Auto Deploy - stateless method to provision ESX hosts limits the lifecycle management of hosts only to using Auto Deploy. But Auto Deploy - stateless allows you to provision hosts with custom images in a heterogeneous cluster.

You can create rules for more than one image that you want to use with the stateless cluster and provision ESX hosts in a single cluster with different images.

Starting with VCF 9.1, Auto Deploy - stateless works with both the Auto Deploy rule engine, which uses iPXE infrastructure, and the Boot Routing Service (BRS), which enables UEFI HTTPS booting.

1. Create a cluster in vCenter that you plan to use for stateless ESX deployments and select **Host Location** pointing to that cluster.

   The cluster defaults to the Auto Deploy - stateful provisioning method.

2. In the **Auto Deploy** tab, select the cluster and click **Enable Stateless Support**.

   The value in the Provisioning Method column changes to **Auto Deploy - stateless**.

3. Create a deploy rule and select the cluster in **Host Location**.

   This step can repeat as many times as the number of images you want to use in the heterogeneous stateless cluster.

4. Click **Deploy Rules**, select the cluster, and click **Edit** to add an image.

   When you create rules for a custom image that you want to use with the stateless cluster, for each rule, click **Hosts that match the following pattern** and then **Add Pattern** to select your custom criteria. For example, you can specify a server vendor. Select the same cluster in **Host Location** and add a custom image for a given OEM for example. This way, different rules can deploy different images to servers in the same cluster.

5. In the **Configuration** step of the wizard, select **Image** and **Host Location**.

6. In the **Select Image** step, select the image that you want to use for stateless provisioning.

7. Activate the rule.

   When you create multiple rules using different images on the same cluster, mind the order of the rules. Make sure that rules for a specific pattern are higher in the list of rules than rules that match all hosts. If a rule that matches all hosts precedes a rule for a specific pattern, all hosts match the image from the preceding rule.

   For example, if you have three rules:

   1. For a custom image in a stateless cluster.
   2. For a VMware image in a stateless cluster,
   3. For stateful installation.

   You can order the rules so that:

   1. The first rule is for the custom image,
   2. The second rule is for all other cases for stateless provisioning,
   3. The third rule covers stateful provisioning.

How Zero Touch Provisioning Works with vSphere Configuration Profiles

You can collectively manage the ESX configuration of a cluster with vSphere Configuration Profiles by using Zero Touch Provisioning.

With Zero Touch Provisioning, you can select between vSphere Lifecycle Manager desired images, vSphere Configuration Profiles on vCenter cluster level, or simply a cluster in a vCenter instance. When you create a cluster, the default provisioning method is Auto Deploy - stateful. You can switch to either Zero Touch Provisioning or Auto Deploy - stateless, but only Auto Deploy - stateful and Zero Touch Provisioning support vSphere Configuration Profiles.

Before you start using Zero Touch Provisioning with vSphere Configuration Profiles, you must have a ready configuration, either in a `.json` file or exported from a reference host. The best practice is to:

- Create a VCP cluster.
- Manually configure the desired settings, such as IP, VMK adapter, virtual switch, and firewall on an existing ESX host that you select as a reference host.
- Import the reference host configuration to create a draft, make changes, precheck, and apply it.

Successful provisioning of hosts in VCP clusters requires a valid, non-empty desired configuration document. If the cluster configuration lacks networking details, Auto Deploy rules might fail, because hosts cannot come online. Always validate the configuration before you create Auto Deploy rules and attempt to provision hosts.

For new clusters, when you complete the vSphere Configuration Profile configuration and create a rule in Auto Deploy, the provisioning method defaults to Auto Deploy - stateful. Select the cluster and click **Enable Zero Touch Provisioning**. Then you can start provisioning all other hosts in the cluster with the Sphere Configuration Profile.

If the imported ESX host is part of a cluster with an active Auto Deploy rule, the new cluster appears under the **Clusters** tab in Auto Deploy.

vSphere Auto Deploy Best Practices

Set up a highly available vSphere Auto Deploy infrastructure in large production environments or when using stateless caching.

Follow best practices when installing vSphere Auto Deploy and when using vSphere Auto Deploy with other vSphere components. Set up a highly available vSphere Auto Deploy infrastructure in large production environments or when using stateless caching. Follow all security guidelines that you would follow in a PXE boot environment, and consider the recommendations in this chapter.

vSphere Auto Deploy Best Practices

Follow vSphere Auto Deploy best practices to set up networking, configure vSphere HA, and optimize your environment for vSphere Auto Deploy.

For Auto Deploy

vSphere Auto Deploy and vSphere HA Best Practices

You can improve the availability of the virtual machines running on hosts provisioned with vSphere Auto Deploy by following best practices.

Some environments configure the hosts provisioned with vSphere Auto Deploy with a distributed switch or configure virtual machines running on the hosts with Auto Start Manager. In such environments, deploy the vCenter system so that its availability matches the availability of the vSphere Auto Deploy server. Several approaches are possible.

- Deploy vCenter. The vSphere Auto Deploy server is included.
- Run vCenter in a vSphere HA enabled cluster and configure the virtual machine with a vSphere HA restart priority of high. Include two or more hosts in the cluster that are not managed by vSphere Auto Deploy and pin the vCenter virtual machine to these hosts by using a rule (vSphere HA DRS required VM to host rule). You can set up the rule and then deactivate DRS if you do not want to use DRS in the cluster. The greater the number of hosts that are not managed by vSphere Auto Deploy, the greater your resilience to host failures.

  Note:
  This approach is not suitable if you use Auto Start Manager. Auto Start Manager is not supported in a cluster enabled for vSphere HA.

vSphere Auto Deploy Networking Best Practices

Prevent networking problems by following vSphere Auto Deploy networking best practices.

vSphere Auto Deploy and IPv6	Because vSphere Auto Deploy takes advantage of the iPXE infrastructure, if the hosts that you plan to provision with vSphere Auto Deploy are with legacy BIOS, the vSphere Auto Deploy server must have an IPv4 address. PXE booting with legacy BIOS firmware is possible only over IPv4. PXE booting with UEFI firmware is possible with either IPv4 or IPv6.
IP Address Allocation	Use DHCP reservations for address allocation. Fixed IP addresses are supported by the host customization mechanism, but providing input for each host is not recommended.
VLAN Considerations	Use vSphere Auto Deploy in environments that do not use VLANs. If you intend to use vSphere Auto Deploy in an environment that uses VLANs, make sure that the hosts that you want to provision can reach the DHCP server. How hosts are assigned to a VLAN depends on the setup at your site. The VLAN ID might be assigned by the switch or the router, or might be set in the host's BIOS or through the host profile. Contact your network administrator to determine the steps for allowing hosts to reach the DHCP server.

vSphere Auto Deploy and VMware Tools Best Practices

When you provision hosts with vSphere Auto Deploy, you can select an image profile that includes VMware Tools, or select the smaller image associated with the image profile that does not contain VMware Tools.

You can download two image profiles from the VMware download site.

- *xxxxx*-standard: An image profile that includes the VMware Tools binaries, required by the guest operating system running inside a virtual machine. The image is usually named esx-*version*-*xxxxx*-standard.
- *xxxxx*-no-tools: An image profile that does not include the VMware Tools binaries. This image profile is usually smaller has a lower memory overhead, and boots faster in a PXE-boot environment. This image is usually named esx-*version*-*xxxxx*-no-tools.

You can deploy ESX using either image profile.

- If the network boot time is of no concern, and your environment has sufficient extra memory and storage overhead, use the image that includes VMware Tools.
- If you find the network boot time too slow when using the standard image, or if you want to save some space on the hosts, you can use the image profile that does not include VMware Tools, and place the VMware Tools binaries on shared storage. See, Provision ESX Host with an Image Profile Without VMware Tools.

vSphere Auto Deploy Load Management Best Practices

Simultaneously booting large numbers of hosts places a significant load on the vSphere Auto Deploy server. Because vSphere Auto Deploy is a Web server at its core, you can use existing Web server scaling technologies to help distribute the load. For example, one or more caching reverse proxy servers can be used with vSphere Auto Deploy. The reverse proxies serve up the static files that make up the majority of an ESX boot image. Configure the reverse proxy to cache static content and pass all requests through to the vSphere Auto Deploy server.

Use multiple TFTP servers to point to different proxy servers. Use one TFTP server for each reverse proxy server. After that, set up the DHCP server to send different hosts to different TFTP servers.

When you boot the hosts, the DHCP server redirects them to different TFTP servers. Each TFTP server redirects hosts to a different server, either the vSphere Auto Deploy server or a reverse proxy server, significantly reducing the load on the vSphere Auto Deploy server.

After a massive power outage, bring up the hosts on a per-cluster basis. If you bring multiple clusters online simultaneously, the vSphere Auto Deploy server might experience CPU bottlenecks. All hosts might come up after a delay. The bottleneck is less severe if you set up the reverse proxy.

vSphere Auto Deploy Logging and Troubleshooting Best Practices

To resolve problems that you encounter with vSphere Auto Deploy, use the vSphere Auto Deploy logging information from the vSphere Client and set up your environment to send logging information and core dumps to remote hosts.

vSphere Auto Deploy Logs	Download the vSphere Auto Deploy logs by going to the vSphere Auto Deploy page in the vSphere Client. See, Download vSphere Auto Deploy Logs.
Setting Up Syslog	Set up a remote syslog server. See the *vCenter and Host Management* documentation for syslog server configuration information. Configure the first host you boot to use the remote syslog server and apply that host's host profile to all other target hosts. Optionally, install and use the vSphere Syslog Collector, a vCenter support tool that provides a unified architecture for system logging, enables network logging, and lets you combine logs from multiple hosts.
Setting Up ESX Dump Collector	Hosts provisioned with vSphere Auto Deploy do not have a local disk to store core dumps on. Install ESX Dump Collector and set up your first host so that all core dumps are directed to ESX Dump Collector, and apply the host profile from that host to all other hosts. See Configure ESX Dump Collector with ESXCLI.

Using vSphere Auto Deploy in a Production Environment

When you move from a proof of concept setup to a production environment, take care to make the environment resilient.

- Protect the vSphere Auto Deploy server. See vSphere Auto Deploy and vSphere HA Best Practices.
- Protect all other servers in your environment, including the DHCP server and the TFTP server.
- Follow VMware security guidelines, including those outlined in vSphere Auto Deploy Security Considerations.

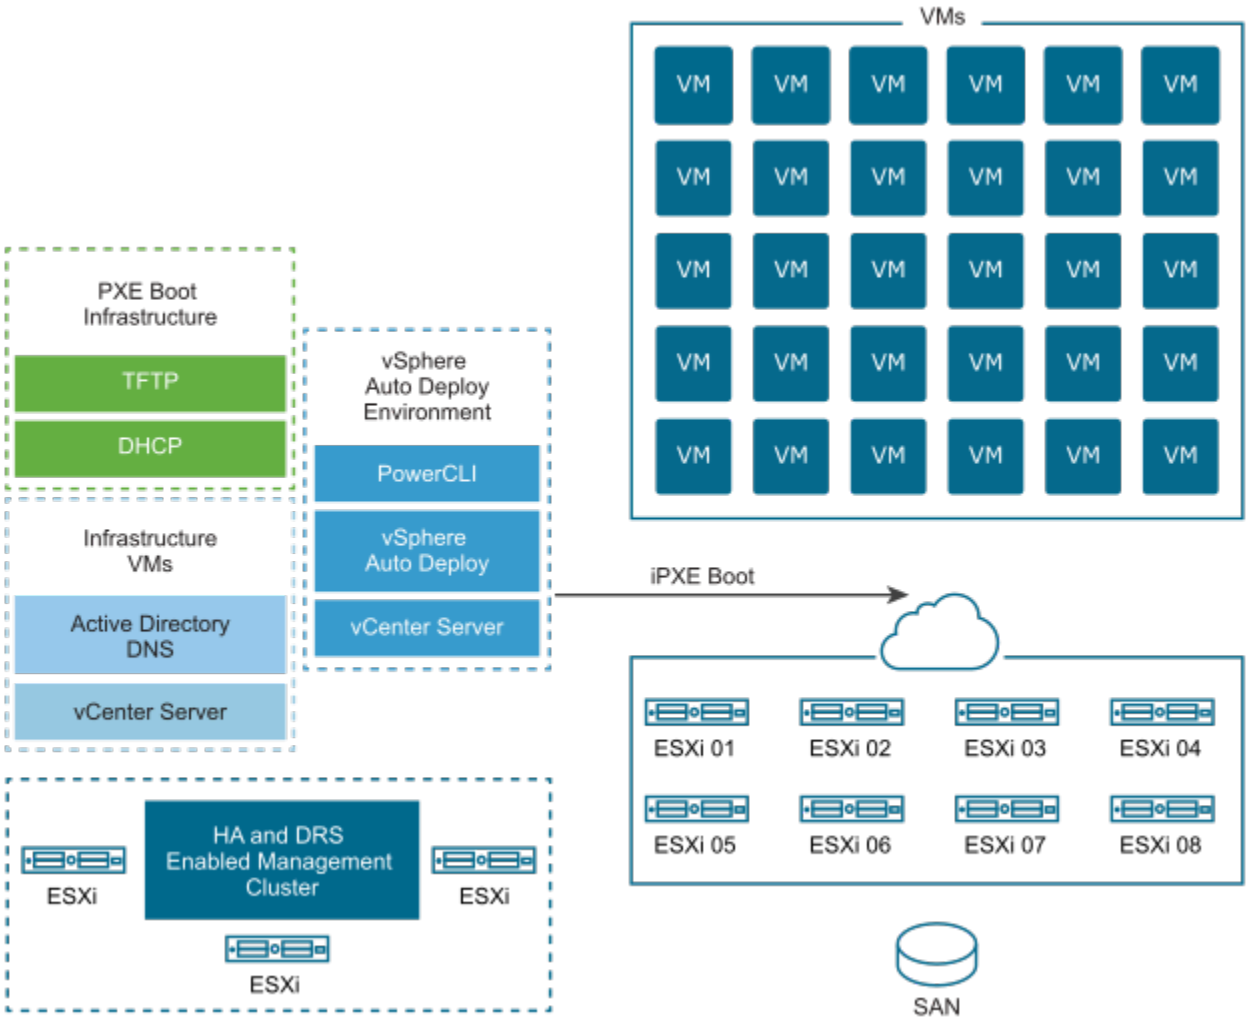
Set Up Highly Available vSphere Auto Deploy Infrastructure

Highly available vSphere Auto Deploy infrastructure prevents data loss and is a prerequisite for using vSphere Auto Deploy with stateless caching.

In many production situations, a highly available vSphere Auto Deploy infrastructure is required to prevent data loss. Such infrastructure is also a prerequisite for using vSphere Auto Deploy with stateless caching.

For the management cluster, install ESX on three hosts. Do not provision the management cluster hosts with vSphere Auto Deploy.

Figure 10: Highly Available vSphere Auto Deploy Infrastructure



1. Enable vSphere HA and vSphere DRS on the management cluster.
2. Set up the following virtual machines on the management cluster.

Infrastructure Component	Description
PXE boot infrastructure	TFTP and DHCP servers.
Infrastructure VM	Active Directory, DNS, vCenter.
vSphere Auto Deploy environment	VCF PowerCLI, vSphere Auto Deploy server, vCenter. Set up this environment on a single virtual machine or on three separate virtual machines in production systems.

   The vCenter on the infrastructure virtual machine differs from the vCenter in the vSphere Auto Deploy environment.
3. Set up vSphere Auto Deploy to provision other hosts as needed.

   Because the components on the management cluster are protected with vSphere HA, high availability is supported.

Device Alias Configuration

Device aliases, also called device names, are short names associated with I/O adapters in an I/O subsystem.

For example, network uplinks have aliases such as vmnic0, vmnic1, and so on. SCSI adapter objects in the storage subsystem and graphics device objects also have aliases. A hardware device can be presented as multiple I/O adapters

in the I/O subsystem. The I/O adapters can be of a different type from the underlying physical device. For example, an FCoE device is a storage I/O adapter that uses NIC hardware. Software iSCSI is a storage adapter using the network stack at the IP layer. Therefore, in the ESX native driver model, aliases formally refer only to I/O adapters, and not to physical devices such as a PCI NIC or a PCI HBA.

Device Alias Assignment

A stateless ESX deployment model is one where the ESX host is not installed on hard disks, and is typically booted by using PXE. A stateful ESX deployment model is one where the ESX host is installed on local hard disks. Device alias assignment occurs during a stateless ESX boot or a fresh installation of stateful ESX. The ESX host assigns aliases to I/O adapters in an order which is based on the underlying hardware enumeration order. The ESX host assigns aliases first to on-board devices and then to add-in cards based on slot order. The ESX host cannot assign aliases to absent devices or devices without supported drivers.

An uplink that uses a NIC that is built into the motherboard receives a vmnicN alias with lower number compared to an uplink of a PCI add-in card. The NIC driver might register more than one uplink. If one of the uplinks does not correspond to an enumerable hardware device, the ESX host assigns the next available alias to the uplink after the uplink is registered with the system.

Persistence of Device Alias Configuration

After the ESX host assigns aliases, alias configuration is persisted. The ESX host attempts to keep the alias of each device the same regardless of the ESX version updates, or hardware changes, such as adding or removing devices from slots.

The persistence of the alias configuration depends on the deployment model.

- In stateful systems, the alias configuration is persisted locally on the host.
- In stateless systems, if you do not manage the stateless system by using host profiles, the alias configuration is not persisted locally on the host.
- In stateful and stateless systems that you manage by using host profiles, the alias configuration is persisted in the host profile. If you apply a host profile to a stateful host, the host profile overrides any locally persisted alias configuration.

Changes in the Device Alias Configuration

The persistence of alias configuration is based on the bus addresses of devices. If the bus address of a device is altered, the persisted alias configuration becomes inapplicable and the aliases assigned to the device might change.

Changes in the device alias configuration might occur in the following cases:

- A driver upgrade might enumerate or present an I/O adapter differently to the system compared to how the I/O adapter is presented before the driver upgrade.
- A stack upgrade might result in changes to parts of a multi-module driver setup, or to the ESX I/O stack that supports a multi-module driver.
- BIOS or device firmware upgrades might lead to incomplete port or slot information.
- Changes in the slot position of a device.

Note:
If you remove a device from the system, the alias configuration of the I/O adapters of the device is removed. If you add the same devices back to the system later, the I/O adapters of the device might not receive their previous aliases.

Device Alias Configuration in ESX Clusters

Initial alias configuration is the same across a cluster of identical systems. However, even on a cluster that is considered homogeneous, small differences in hardware or firmware might result in differences in the alias configuration between hosts.

Differences in the processing order during driver binding can also result in differences in alias configuration. For example, a NIC driver registers two uplinks, uplink-1 and uplink-2, for two ports of the same PCI device, where one of the ports is not hardware enumerable by the system. Timing changes in the order of registration of the uplinks might result in

differences in how the ESX hosts assign aliases to the uplinks. One ESX host might assign the hardware-based alias to uplink-1, and another ESX host might assign the hardware-based alias to uplink-2.

To match alias configuration across homogeneous hosts, you can use host profiles. The Device Alias Configuration host profile applies alias configuration to an ESX host by mapping devices in the alias configuration to the ESX host devices. The mapping operation is based on the hardware information sources that are used as the basis for initial alias assignment. For more information about information sources used for alias assignment, see KB 2091560.

The Device Alias Configuration host profile also flags errors, for example, when a device is present in the host profile but not present on the host.

A heterogeneous cluster does not have the same default alias configuration across its hosts. Due to the differences between the devices, a host profile cannot be applied cleanly.

Using ESX Shell Commands to View Device Alias Information

On a running ESX system, you can view information about I/O adapter aliases by running commands in an ESX Shell.

Using ESX Shell Commands to View Device Alias Information

Command	Description
`device alias list`	Lists all current I/O adapter aliases.
`device alias get -n<alias>`	Displays the physical device that an I/O adapter alias maps to.
`network nic list`	Lists aliases and general information about network devices.
`storage core adapter list`	Lists all storage I/O adapters.

> **Note:**
> ESXCLI commands are supported commands. Using alternative sources for displaying alias information is not recommended.

Change Device Aliases on an ESX Host by Using Host Profiles

You can modify a device alias on ESX hosts by editing the device alias section of the host profile attached to the hosts.

A device alias change can occur, for example, when you apply a BIOS or device firmware update. For more information about changes in the device alias configuration, see Device Alias Configuration.

I/O adapters that are based on PCI hardware usually have a logical and a PCI alias entry. Both aliases must have the same value. Some I/O adapters usually have a logical alias entry only. PCI hardware devices without I/O adapters usually have a PCI alias entry only. Modify a PCI alias entry only when you need the alias for another device.

> **Note:**
> Two different I/O adapters must not have the same alias, except I/O adapters that are based on PCI hardware and have a logical and a PCI alias entry.

Procedure

For information about exporting, extracting, and editing a host profile, see the *vSphere Host Profiles* documentation.

1. Export the current host profile attached to the ESX host.
2. Extract a new host profile from the ESX host, but do not apply the host profile.
3. Remove all entries from the device alias section of the current host profile.
4. Transfer all entries from the device alias section of the new host profile to the same section of the current host profile. You can modify the aliases in the entries before adding them to the current host profile.
5. Reapply the current host profile to the ESX host.

Change Device Aliases on a Stateful ESX Host by Using ESXCLI Commands

You can modify a device alias on a stateful ESX host that does not have an attached host profile by running ESXCLI commands on the host.

A device alias change can occur, for example, when the slot position of a device changes. For more information about changes in the device alias configuration, see Device Alias Configuration.

Note:
The following ESXCLI commands might not be compatible with ESX version 6.7 and earlier.

1. To list the current assignment of aliases to device addresses, in the ESX Shell, run `localcli --plugin-dir /usr/lib/vmware/esxcli/int/ deviceInternal alias list`.

   For I/O adapters that are based on PCI hardware, you usually see a logical and a PCI alias entry.

   For some I/O adapters, you usually see a logical alias entry only.

   For PCI hardware devices without I/O adapters, you usually see a PCI alias entry only.

2. To change an alias, replace the `ALIAS`, `PCI_ADDRESS`, and `LOGICAL_ADDRESS` placeholder values with actual values, and follow one of the substeps.
   a) If an I/O adapter has a logical and a PCI alias, run `localcli --plugin-dir /usr/lib/vmware/esxcli/int/ deviceInternal alias store --bus-type logical --alias ALIAS --bus-address LOGICAL_ADDRESS` and `localcli --plugin-dir /usr/lib/vmware/esxcli/int/ deviceInternal alias store --bus-type pci --alias ALIAS --bus-address PCI_ADDRESS`.

      The logical and PCI aliases must have the same value.
   b) If an I/O adapter has a logical alias entry only, run `localcli --plugin-dir /usr/lib/vmware/esxcli/int/ deviceInternal alias store --bus-type logical --alias ALIAS --bus-address LOGICAL_ADDRESS`.
   c) If a PCI hardware device has a PCI alias entry only, run `localcli --plugin-dir /usr/lib/vmware/esxcli/int/ deviceInternal alias store --bus-type pci --alias ALIAS --bus-address PCI_ADDRESS`.

      Modify a PCI alias only when you need the alias for another device.

   Note:
   Two different I/O adapters must not have the same alias, except I/O adapters that are based on PCI hardware and have a logical and a PCI alias entry.

3. Reboot the system.

vSphere PowerCLI Scenario for vSphere Auto Deploy

Scenario to set up and configure a working vSphere Auto Deploy environment by using PowerCLI.

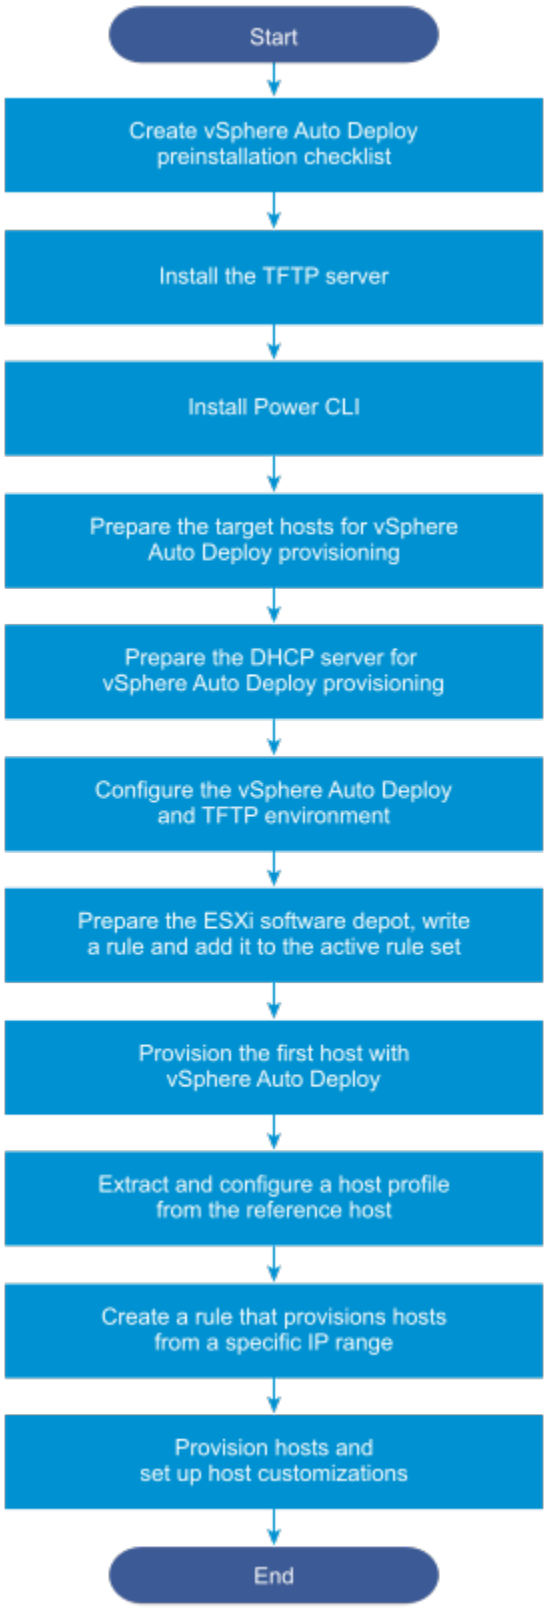
In this scenario, you are going to set up and configure a working vSphere Auto Deploy environment that includes four hosts. You will create rules and provision two of the hosts with an image profile and the other two with the same image profile and a host profile that is set up to prompt for user input. This scenario can provide you with the basis for a production environment. The task descriptions assume that you are using a flat network with no VLAN tagging between the physical hosts and the rest of your environment.

To perform the tasks in this scenario, you should have the following background knowledge and privileges.

- Experience with vSphere (vCenter and ESX).
- Basic knowledge of Microsoft PowerShell and VCF PowerCLI.
- Administrator rights to a Windows system and a vCenter system.

Follow the tasks in the order presented in this scenario. Some steps can be performed in a different order, but the order used here limits repeated manipulation of some components. For details on the preinstallation checklist and other prerequisites to configure vSphere Auto Deploy, see Install and Configure vSphere Auto Deploy.

Figure 11: vSphere Auto Deploy Setup and Hosts Provisioning Workflow



vSphere Auto Deploy takes advantage of the iPXE infrastructure and PXE booting with legacy BIOS firmware is possible only over IPv4. If the hosts that you want to provision with vSphere Auto Deploy are with legacy BIOS, the vSphere Auto Deploy server must have an IPv4 address. PXE booting with UEFI firmware is possible with either IPv4 or IPv6.

Install the TFTP Server

To set up a vSphere Auto Deploy infrastructure, you must install a TFTP server in your environment. vSphere Auto Deploy relies on a TFTP server for sending a boot image to the hosts that it provisions.

This task only installs the TFTP server. You later download a configuration file to the server. See Configure the vSphere Auto Deploy and TFTP Environment in the vSphere Client.

1. Download your preferred TFTP server to a location that has network access to your vCenter and install the server.
2. Configure the TFTP root directory, for example `D:\TFTP_Root\`.

Install VCF PowerCLI, to manage vSphere Auto Deploy with VCF PowerCLI cmdlets.

Install VCF PowerCLI

Before you can manage vSphere Auto Deploy with rules that you create with VCF PowerCLI cmdlets, you must install VCF PowerCLI.

Use the VMware PowerCLI User's Guide to learn about PowerShell basics, VCF PowerCLI concepts, and how to install and configure VCF PowerCLI.

Configure the settings of your target hosts to prepare them for provisioning with vSphere Auto Deploy.

Prepare the vSphere Auto Deploy Target Hosts

You must configure the BIOS settings of the four hosts and reconfirm the MAC address of the primary network device to prepare the target hosts for provisioning with vSphere Auto Deploy.

Hosts that you want to provision with vSphere Auto Deploy must meet the requirements for ESX.

See ESX Hardware Requirements.

1. Change the BIOS settings of each of the four physical hosts to force the hosts to boot from the primary network device.
2. Reconfirm the MAC address of the primary network device.

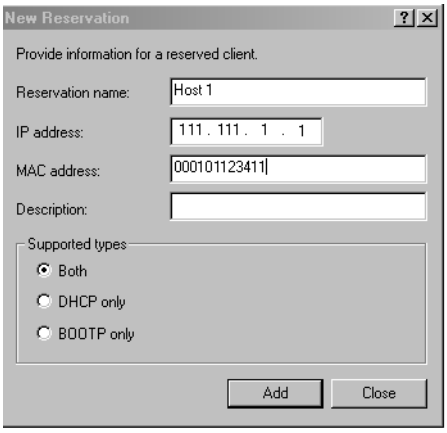
Set up the DHCP server to serve each target host with an iPXE binary.

Prepare the DHCP Server for vSphere Auto Deploy Provisioning

When you prepare the vSphere Auto Deploy target hosts, you must set up the DHCP server in this scenario to serve each target host with an iPXE binary.

The environment in this scenario uses Active Directory with DNS and DHCP. The DHCP server is included in the vSphere supported Windows Server versions.

1. Log in to your DHCP Server with administrator privileges.
2. Create a DHCP scope for your IP address range.
   a) Click **Start > Settings > Control Panel > Administrative Tools** and click **DHCP**.
   b) Navigate to **DHCP** > ***hostname*** > **IPv4**.
   c) Right-click **IPv4** and select **New Scope**.
   d) On the Welcome screen, click **Next**, and specify a name and description for the scope.
   e) Specify an IP address range and click **Next**.
   f) Click **Next** until you reach the Configure DHCP Options screen and select **No, I will configure this option later**.
3. Create a DHCP reservation for each target ESX host.
   a) In the DHCP window, navigate to **DHCP** > ***hostname*** > **IPv4** > **Autodeploy Scope** > **Reservations**.
   b) Right-click **Reservations** and select **New Reservation**.
   c) In the New Reservation window, specify a name, IP address, and the MAC address for one of the hosts. Do not include the colon (:) in the MAC address.



d) Repeat the process for each of the other hosts.

4. Set up the DHCP Server to point the hosts to the TFTP Server.
   a) In the DHCP window, navigate to **DHCP** > ***hostname*** > **IPv4** > **Autodeploy Scope** > **Scope Options**.
   b) Right click **Scope Options** and choose **Configure Options**.
   c) In the Scope Options window, click the **General** tab.
   d) Click **066 Boot Server Host Name** and enter the address of the TFTP server that you installed in the String value field below the Available Options.

   e) Click **067 Bootfile Name** and enter `undionly.kpxe.vmw-hardwired`.

      The `undionly.kpxe.vmw-hardwired` iPXE binary will be used to boot the ESX hosts.
   f) Click **Apply** and click **OK** to close the window.

5. In the DHCP window, right-click **DHCP** > ***hostname*** > **IPv4** > **Scope** > **Activate** and click **Activate**.
6. Do not log out from the DHCP Server if you are using Active Directory for DHCP and DNS, or log out otherwise.

Start the vCenter service of vSphere Auto Deploy and configure the TFTP server.

Configure the vSphere Auto Deploy and TFTP Environment in the vSphere Client

After you prepare the DHCP server, you must start the vSphere Auto Deploy vCenter service and configure the TFTP server. You must download a TFTP ZIP file from your vSphere Auto Deploy server. The customized FTP server serves the boot images that vSphere Auto Deploy provides.

1. Use the vSphere Client to connect to the vCenter system that manages the vSphere Auto Deploy server.
2. Start the vSphere Auto Deploy service.
   a) Navigate to **Home** > **Auto Deploy**.
   b) On the **Auto Deploy** page, select your vCenter from the drop-down menu at the top.
   c) Click **Enable Auto Deploy and Image Builder** to activate the service.

      If the **Image Builder** service is already active, select the **Configure** tab and click **Enable Auto Deploy Service**.

3. In the Auto Deploy inventory, click the **Configure** tab.
4. Click the **Download TFTP Zip File**.
5. Save the file `deploy-tftp.zip` to the `TFTP_Root` directory that you created when you installed the TFTP Server, and unzip the file.

Add a software depot to your inventory and use an image profile from the depot to create a rule for host provisioning.

Prepare the ESX Software Depot and Write a Rule

After you configure the vSphere Auto Deploy infrastructure, you must add an ESX software depot, specify an image profile, write a rule, and add it to the active rule set.

Verify that you can access the ESX hosts that you want to provision from the system on which you run VCF PowerCLI.

vSphere Auto Deploy provisions hosts with image profiles that define the set of VIBs that an ESX installation process uses. Image profiles are stored in software depots. You must make sure that the correct image profile is available before you start provisioning hosts. When you add a software depot to a VCF PowerCLI session, it is available only during the current session. It does not persist across sessions.

The steps in this task instruct you to run VCF PowerCLI cmdlets. For additional information about the vSphere Auto Deploy cmdlets that you can run in a VCF PowerCLI session, see Inventory of vSphere Auto Deploy VCF PowerCLI Cmdlets.

1. Log in as an administrator to the console of the Windows system, either directly or by using RDP.

   This task assumes that you installed VCF PowerCLI on the system on which the vCenter system is running.
2. In a VCF PowerCLI session, run the `Connect-VIServer` cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate issues occur. In a development environment, you can ignore the warning.
3. Enter the vCenter credentials.
4. Run `Add-EsxSoftwareDepot` to add the online depot to the VCF PowerCLI session.

   ```
   Add-EsxSoftwareDepot https://dl.broadcom.com/<Download Token>/PROD/COMP/ESX_HOST/main/vmw-depot-index.xml
   ```

   Adding the software depot is required each time you start a new VCF PowerCLI session.

   Note:

   The URLs of the official VMware online depot are now unique for each customer. To update the download sources URLs, see the following KB articles: 390121 and 390123 .
5. Validate that you successfully added the software depot by checking the contents of the depot with the `Get-EsxImageProfile` cmdlet.

   The cmdlet returns information about all image profiles in the depot.
6. Create a new rule by running the `New-DeployRule` cmdlet.

   ```
   New-DeployRule -Name "InitialBootRule" -Item ESX-9.0.0-xxxxxxx-standard -AllHosts
   ```

   The cmdlet creates a rule that assigns the specified image profile to all hosts in the inventory.
7. Add the new rule to the active rule set to make the rule available to the vSphere Auto Deploy server.

   ```
   Add-DeployRule -DeployRule "InitialBootRule"
   ```

Provision your first host with vSphere Auto Deploy and verify its image provisioning.

Provision the First Host with vSphere Auto Deploy

After creating a rule and adding it to the active rule set, you can provision the first host and check its vCenter location to complete verification of the image provisioning of your setup.

1. Open a console session to the physical host that you want to use as the first ESX target host, boot the host, and look for messages that indicate a successful iPXE boot.

   During the boot process, DHCP assigns an IP address to the host. The IP address matches the name you specified earlier in the DNS server. The host contacts the vSphere Auto Deploy server and downloads the ESX binaries from the HTTP URL indicated in the iPXE tramp file that you downloaded earlier to the TFTP_Root directory. Each instance of vSphere Auto Deploy produces a custom set of files for the TFTP Server.
2. Use the vSphere Client to connect to the vCenter system that manages the vSphere Auto Deploy server.
3. On the vSphere Client Home page, click **Hosts and Clusters**.
4. Verify that the newly provisioned host is now in the vCenter inventory at the datacenter level.

   By default, vSphere Auto Deploy adds hosts at the datacenter level when the boot process completes.

Extract a host profile from the host and configure it to require user input.

Extract and Configure a Host Profile from the Reference Host

After provisioning the first host, you can extract and configure a host profile that can be used to apply the same configuration to other target hosts. Configuration that differs for different hosts, such as a static IP address, can be managed through the host customization mechanism.

vSphere Auto Deploy can provision each host with the same host profile. vSphere Auto Deploy can also use host customization that allows you to specify different information for different hosts. For example, if you set up a VMkernel port for vSphere vMotion or for storage, you can specify a static IP address for the port by using the host customization mechanism.

1. Use the vSphere Client to connect to the vCenter system that manages the vSphere Auto Deploy server.
2. Click **Policies and Profiles** and select **Host Profiles**.
3. Click **Extract Host Profile**.
4. On the **Select host** page of the wizard, select the reference host that you configured earlier and click **Next**.
5. On the **Name and Description** page of the wizard, enter a name and description for the new profile and click **Finish**.
6. Select the host profile that you want to edit and click the **Configure** tab.
7. Click **Edit Host Profile**.
8. Select **Security and Services** > **Security Settings** > **Security** > **User Configuration** > **root**.
9. From the **Password** drop-down menu, select **User Input Password Configuration**.
10. Click **Save** to configure the host profile settings.

Create a vSphere Auto Deploy rule to apply the host profile to other ESX hosts.

Create a Rule that Provisions Hosts from a Specific IP Range

After creating a host profile from a reference host, you can create a rule that applies the previously verified image profile and the host profile that you extracted to target hosts from a specific IP range.

1. Log in with administrator privileges to the console of the Windows system, either directly or by using RDP.
2. In a VCF PowerCLI session, run the `Connect-VIServer` cmdlet to connect to the vCenter system that vSphere Auto Deploy is registered with.

   ```
   Connect-VIServer ipv4_address
   ```

   The cmdlet might return a server certificate warning. In a production environment, make sure no server certificate issues occur. In a development environment, you can ignore the warning.
3. Run `Add-EsxSoftwareDepot` to add the online depot to the VCF PowerCLI session.

   ```
   Add-EsxSoftwareDepot https://dl.broadcom.com/<Download Token>/PROD/COMP/ESX_HOST/main/vmw-depot-index.xml
   ```

   Adding the software depot is required each time you start a new VCF PowerCLI session.

Note:

The URLs of the official VMware online depot are now unique for each customer. To update the download sources URLs, see the following KB articles: 390121 and 390123 .

4. Required: Display the rules in the active rule set by running the `Get-DeployRuleset` cmdlet.
5. Create a rule that instructs vSphere Auto Deploy to provision the set of hosts from a specified IP range with the image profile that you previously selected and the host profile that you created from the reference host.

   ```
   New-DeployRule -name "Production01Rule" -item "image_profile",ESXGold -Pattern "ipv4=IP_range"
   ```

6. Add the new rule to the active rule set.

   ```
   Add-DeployRule -DeployRule "Production01Rule"
   ```

7. Check the active rule set by running the `Get-DeployRuleset` command.

   VCF PowerCLI displays information similar to the following example.

   ```
   Name:              Production01Rule
   PatternList:       {ipv4=address_range}
   ItemList:          {ESX-version-XXXXXX-standard, Compute01, ESXGold}
   ```

Provision the hosts and set up the host customizations.

Provision Hosts and Set Up Host Customizations

With the rule in place that provisions hosts using an image profile and a host profile, you can provision specific target hosts. If any host profile items are set to prompt the user for input, the host comes up in maintenance mode. You apply the host profile or check host compliance to be prompted for the information. The system associates the host customization with the host.

1. Boot the remaining hosts you want to provision.

   vSphere Auto Deploy boots the hosts, applies the host profile, and adds the hosts to the vCenter inventory. The hosts remain in maintenance mode because the host profile from the reference host is set up to require user input for each host.

2. Use the vSphere Client to connect to the vCenter system that manages the vSphere Auto Deploy server.
3. Click **Policies and Profiles** and select **Host Profiles**.
4. Right-click the newly created host profile for Auto Deploy and click **Edit Host Customizations**.
5. Select the hosts, enter the required host customizations and click **Finish**.

   Alternatively, you can also **Import Host Customizations** file.

6. Apply the host profile to each of the hosts and get the hosts out of maintenance mode. Alternatively, you can reboot each host.

   When the reboot progress completes, all hosts are running with the image you specify and use the configuration in the reference host profile. The cluster shows that all hosts are fully compliant.

All hosts are now configured with the shared information through the reference host profile and with the host-specific information through the host customization mechanism. The next time you boot the hosts, they receive the complete Host Profile information, including the host-specific information, and boot up completely configured and out of Maintenance Mode.

Troubleshooting vSphere Auto Deploy

The vSphere Auto Deploy troubleshooting topics cover some situations when provisioning hosts with vSphere Auto Deploy does not work as expected.

- vSphere Auto Deploy TFTP Timeout Error at Boot Time
- vSphere Auto Deploy Host Boots with Wrong Configuration
- Host Is Not Redirected to vSphere Auto Deploy Server

- Package Warning Message When You Assign an Image Profile to a vSphere Auto Deploy Host
- vSphere Auto Deploy Host with a Built-In USB Flash Drive Does Not Send Coredumps to Local Disk
- vSphere Auto Deploy Host Reboots After Five Minutes
- vSphere Auto Deploy Host Cannot Contact TFTP Server
- vSphere Auto Deploy Host Cannot Retrieve ESX Image from vSphere Auto Deploy Server
- vSphere Auto Deploy Host Does Not Get a DHCP Assigned Address
- vSphere Auto Deploy Host Does Not Network Boot
- Recovering from Database Corruption on the vSphere Auto Deploy Server

vSphere Auto Deploy Rule Takes Long to Complete

After you run an Auto Deploy rule, it takes long to complete, and you see no progress for the tasks.

Auto Deploy automatically detects if a new version of the image that a cluster uses is available, or when the cache lifetime of files expires, and refreshes the cache by re-downloading the files from the latest version of the software depot. As a result, you might see a delay in the implementation of Auto Deploy rules.

When the cache lifetime of files cached by Auto Deploy expires, Auto Deploy automatically refreshes the cache from the software depot. Since a default software depot is usually more than 300 MB, depending on the network, the download might take long.

You can also see a delay in deploying Auto Deploy rules when converting a cluster that you manage with a single image to one that you manage with vSphere Configuration Profiles. If a host attempts to boot during the time Auto Deploy caches the configuration file, you might see a delay, because of the time Auto Deploy needs to create the cache.

A general vSphere infrastructure problem might also prevent Auto Deploy rules from running in a timely manner.

Regardless of any connectivity issues or breakage, Auto Deploy keeps active sessions and persists in booting hosts until it succeeds.

vSphere Auto Deploy TFTP Timeout Error at Boot Time

A TFTP Timeout error message appears when a host provisioned with vSphere Auto Deploy boots. The text of the message depends on the BIOS.

A TFTP Timeout error message appears when a host provisioned with vSphere Auto Deploy boots. The text of the message depends on the BIOS.

The TFTP server is down or unreachable.

- Ensure that your TFTP service is running and reachable by the host that you are trying to boot.
- To view the diagnostic logs for details on the present error, see your TFTP service documentation.

vSphere Auto Deploy Host Boots with Wrong Configuration

A host is booting with a different ESX image, host profile, or folder location than the one specified in the rules.

A host is booting with a different ESX image profile or configuration than the image profile or configuration that the rules specify. For example, you change the rules to assign a different image profile, but the host still uses the old image profile.

After the host has been added to a vCenter system, the boot configuration is determined by the vCenter system. The vCenter system associates an image profile, host profile, or folder location with the host.

Use the `Test-DeployRuleSetCompliance` and `Repair-DeployRuleSetCompliance` vSphere PowerCLI cmdlets to reevalute the rules and to associate the correct image profile, host profile, or folder location with the host.

Host Is Not Redirected to vSphere Auto Deploy Server

During boot, a host that you want to provision with vSphere Auto Deploy loads iPXE. The host is not redirected to the vSphere Auto Deploy server.

During boot, a host that you want to provision with vSphere Auto Deploy loads iPXE. The host is not redirected to the vSphere Auto Deploy server.

The `tramp` file that is included in the TFTP ZIP file has the wrong IP address for the vSphere Auto Deploy server.

Correct the IP address of the vSphere Auto Deploy server in the `tramp` file, as explained in the *vSphere Installation and Setup* documentation.

Package Warning Message When You Assign an Image Profile to a vSphere Auto Deploy Host

When you run a vSphere PowerCLI cmdlet that assigns an image profile that is not vSphere Auto Deploy ready, a warning message appears.

When you write or modify rules to assign an image profile to one or more hosts, the following error results:

```
Warning: Image Profile <name-here> contains one or more software packages that are not stateless-ready. You may experience problems when using this profile with Auto Deploy.
```

Each VIB in an image profile has a `stateless-ready` flag that indicates that the VIB is meant for use with vSphere Auto Deploy. You get the error if you attempt to write a vSphere Auto Deploy rule that uses an image profile in which one or more VIBs have that flag set to FALSE.

> **Note:**
> You can use hosts provisioned with vSphere Auto Deploy that include VIBs that are not stateless ready without problems. However booting with an image profile that includes VIBs that are not stateless ready is treated like a fresh install. Each time you boot the host, you lose any configuration data that would otherwise be available across reboots for hosts provisioned with vSphere Auto Deploy.

1. Use vSphere ESX Image Builder cmdlets in a vSphere PowerCLI session to view the VIBs in the image profile.
2. Remove any VIBs that are not stateless-ready.
3. Rerun the vSphere Auto Deploy cmdlet.

vSphere Auto Deploy Host with a Built-In USB Flash Drive Does Not Send Coredumps to Local Disk

If your vSphere Auto Deploy host has a built-in USB flash drive, and an error results in a coredump, the coredump is lost. Set up your system to use ESX Dump Collector to store coredumps on a networked host.

If your vSphere Auto Deploy host has a built-in USB Flash, and if it encounters an error that results in a coredump, the coredump is not sent to the local disk.

1. Install ESX Dump Collector on a system of your choice.

   ESX Dump Collector is included with the vCenter installer.
2. Use ESXCLI to configure the host to use ESX Dump Collector.

   ```
   esxcli conn_options system coredump network set IP-addr,port
   esxcli system coredump network set -e true
   ```
3. Use ESXCLI to deactivate local coredump partitions.

   ```
   esxcli conn_options system coredump partition set -e false
   ```

vSphere Auto Deploy Host Reboots After Five Minutes

A vSphere Auto Deploy host boots and displays iPXE information, but reboots after five minutes.

A host to be provisioned with vSphere Auto Deploy boots from iPXE and displays iPXE information on the console. However, after five minutes, the host displays the following message to the console and reboots.

```
This host is attempting to network-boot using VMware
AutoDeploy. However, there is no ESX  image associated with this host.
Details: No rules containing an Image Profile match this
host. You can create a rule with the New-DeployRule PowerCLI cmdlet
```

```
and add it to the rule set with Add-DeployRule or Set-DeployRuleSet.
The rule should have a pattern that matches one or more of the attributes
listed below.
```

The host might also display the following details:

```
Details: This host has been added to VC, but no Image Profile
is associated with it. You can use Apply-ESXImageProfile in the
PowerCLI to associate an Image Profile with this host.
Alternatively, you can reevaluate the rules for this host with the
Test-DeployRuleSetCompliance and Repair-DeployRuleSetCompliance cmdlets.
```

The console then displays the host's machine attributes including vendor, serial number, IP address, and so on.

No image profile is currently associated with this host.

You can assign an image profile to the host by running the `Apply-EsxImageProfile` cmdlet, or by creating the following rule:

1. Run the `New-DeployRule` cmdlet to create a rule that includes a pattern that matches the host with an image profile.
2. Run the `Add-DeployRule` cmdlet to add the rule to a ruleset.
3. Run the `Test-DeployRuleSetCompliance` cmdlet and use the output of that cmdlet as the input to the `Repair-DeployRuleSetCompliance` cmdlet.

vSphere Auto Deploy Host Cannot Contact TFTP Server

The host that you provision with vSphere Auto Deploy cannot contact the TFTP server.

When you attempt to boot a host provisioned with vSphere Auto Deploy, the host performs a network boot and is assigned a DHCP address by the DHCP server, but the host cannot contact the TFTP server.

The TFTP server might have stopped running, or a firewall might block the TFTP port.

- If you installed the WinAgents TFTP server, open the WinAgents TFTP management console and verify that the service is running. If the service is running, check the Windows firewall's inbound rules to make sure the TFTP port is not blocked. Turn off the firewall temporarily to see whether the firewall is the problem.
- For all other TFTP servers, see the server documentation for debugging procedures.

vSphere Auto Deploy Host Cannot Retrieve ESX Image from vSphere Auto Deploy Server

The host that you provision with vSphere Auto Deploy stops at the iPXE boot screen.

When you attempt to boot a host provisioned with vSphere Auto Deploy, the boot process stops at the iPXE boot screen and the status message indicates that the host is attempting to get the ESX image from the vSphere Auto Deploy server.

The vSphere Auto Deploy service might be stopped or the vSphere Auto Deploy server might be inaccessible.

1. Log in to the system on which you installed the vSphere Auto Deploy server.
2. Check that the vSphere Auto Deploy server is running.
   a) Click **Start** > **Settings** > **Control Panel** > **Administrative Tools**.
   b) Double-click **Services** to open the Services Management panel.
   c) In the Services field, look for the VMware vSphere Auto Deploy Waiter service and restart the service if it is not running.
3. Open a Web browser, enter the following URL, and check whether the vSphere Auto Deploy server is accessible.
   https://*Auto_Deploy_Server_IP_Address*:*Auto_Deploy_Server_Port*/vmw/rdb

   Note:
   Use this address only to check whether the server is accessible.

4. If the server is not accessible, a firewall problem is likely.
   a) Try setting up permissive TCP Inbound rules for the vSphere Auto Deploy server port.

      The port is 6501 unless you specified a different port during installation.
   b) As a last resort, deactivate the firewall temporarily and enable it again after you verified whether it blocked the traffic. Do not deactivate the firewall on production environments.

      To deactivate the firewall, run `netsh firewall set opmode disable`. To enable the firewall, run `netsh firewall set opmode enable`.

vSphere Auto Deploy Host Does Not Get a DHCP Assigned Address

The host you provision with vSphere Auto Deploy fails to get a DHCP Address.

When you attempt to boot a host provisioned with vSphere Auto Deploy, the host performs a network boot but is not assigned a DHCP address. The vSphere Auto Deploy server cannot provision the host with the image profile.

You might have a problem with the DHCP service or with the firewall setup.

1. Check that the DHCP server service is running on the Windows system on which the DHCP server is set up to provision hosts.
   a) Click **Start** > **Settings** > **Control Panel** > **Administrative Tools**.
   b) Double-click **Services** to open the Services Management panel.
   c) In the Services field, look for the DHCP server service and restart the service if it is not running.
2. If the DHCP server is running, recheck the DHCP scope and the DHCP reservations that you configured for your target hosts.

   If the DHCP scope and reservations are configured correctly, the problem most likely involves the firewall.
3. As a temporary workaround, turn off the firewall to see whether that resolves the problem.
   a) Open the command prompt by clicking **Start** > **Program** > **Accessories** > **Command prompt**.
   b) Type the following command to temporarily turn off the firewall. Do not turn off the firewall in a production environment.

      ```
      netsh firewall set opmode disable
      ```
   c) Attempt to provision the host with vSphere Auto Deploy.
   d) Type the following command to turn the firewall back on.

      ```
      netsh firewall set opmode enable
      ```
4. Set up rules to allow DHCP network traffic to the target hosts.

   See the firewall documentation for DHCP and for the Windows system on which the DHCP server is running for details.

vSphere Auto Deploy Host Does Not Network Boot

The host you provision with vSphere Auto Deploy comes up but does not network boot.

When you attempt to boot a host provisioned with vSphere Auto Deploy, the host does not start the network boot process.

You did not enable your host for network boot.

1. Reboot the host and follow the on-screen instructions to access the BIOS configuration.
2. In the BIOS configuration, enable Network Boot in the Boot Device configuration.

Recovering from Database Corruption on the vSphere Auto Deploy Server

In some situations, you might have a problem with the vSphere Auto Deploy database. The most efficient recovery option is to replace the existing database file with the most recent backup.

When you use vSphere Auto Deploy to provision the ESX hosts in your environment, you might encounter a problem with the vSphere Auto Deploy database.

Important:
This is a rare problem. Follow all other vSphere Auto Deploy troubleshooting strategies before you replace the current database file. Rules or associations that you created since the backup you choose are lost.

This problem happens only with hosts that are provisioned with vSphere Auto Deploy.

1. Stop the vSphere Auto Deploy server service.
2. Find the vSphere Auto Deploy log by going to the vSphere Auto Deploy page in the vSphere Client.
3. Check the logs for the following message:
   `DatabaseError: database disk image is malformed.`
   If you see the message, replace the existing database with the most recent backup.
4. Go to the vSphere Auto Deploy data directory at `/var/lib/rbd`.
   The directory contains a file named `db`, and backup files named `db-yyy-mm-dd`.
5. Rename the current `db` file.
   VMware Support might ask for that file if you call for assistance.
6. Rename the most recent backup to `db`.
7. Restart the vSphere Auto Deploy server service.
8. If the message still appears in the log, repeat the steps to use the next recent backup until vSphere Auto Deploy works without database errors.

Setting Up ESX

These topics provide information about using the direct console user interface and configuring defaults for ESX.

- ESX Autoconfiguration
- About the Direct Console ESX Interface
- Enable ESX Shell and SSH Access with the Direct Console User Interface
- Set the Password for the Administrator Account
- Configuring the BIOS Boot Settings
- Configuring Network Settings
- Configure System Logging

Initial ESX Configuration

- ESX Autoconfiguration
- Managing ESX Remotely
- About the Direct Console ESX Interface
- Configure the Keyboard Layout for the Direct Console
- Create a Security Banner for the Direct Console
- Redirecting the Direct Console to a Serial Port
- Redirect the Direct Console to a Serial Port by Setting the Boot Options Manually
- Redirect the Direct Console to a Serial Port from the vSphere Client
- Redirect the Direct Console to a Serial Port in a Host Deployed with Auto Deploy

ESX Autoconfiguration

When you turn on the ESX host for the first time or after resetting the configuration defaults, the host enters an autoconfiguration phase. This phase configures system network and storage devices with default settings.

By default, Dynamic Host Configuration Protocol (DHCP) configures IP, and all visible blank internal disks are formatted with the virtual machine file system (VMFS) so that virtual machines can be stored on the disks.

Managing ESX Remotely

You can use the VMware Host Client, the vSphere Client, and vCenter to manage your ESX hosts.

For instructions about downloading and installing vCenter and the vCenter components, see *vCenter Deployment and Setup*. For information about installing the VMware Host Client, see *vSphere Single Host Management*.

About the Direct Console ESX Interface

Use the direct console interface for initial ESX configuration and troubleshooting.

Connect a keyboard and monitor to the host to use the direct console. After the host completes the autoconfiguration phase, the direct console appears on the monitor. You can examine the default network configuration and change any settings that are not compatible with your network environment.

Key operations available to you in the direct console include:

- Configuring hosts
- Setting up administrative access
- Troubleshooting

You can also use vSphere Client to manage the host by using vCenter.

Table 25: Navigating in the Direct Console

Action	Key
View and change the configuration	F2
Change the user interface to high-contrast mode	F4
Shut down or restart the host	F12
View the VMkernel log	Alt+F12
Switch to the shell console	Alt+F1
Switch to the direct console user interface	Alt+F2
Move the selection between fields	Arrow keys
Select a menu item	Enter
Toggle a value	Spacebar
Confirm sensitive commands, such as resetting configuration defaults	F11
Save and exit	Enter
Exit without saving	Esc
Exit system logs	q

Configure the Keyboard Layout for the Direct Console

You can configure the layout for the keyboard that you use with the direct console.

1. From the direct console, select **Configure Keyboard** and press Enter.
2. Select the layout to use.
3. Press the spacebar to toggle selections on and off.
4. Press Enter.

Create a Security Banner for the Direct Console

A security banner is a message that is displayed on the direct console **Welcome** screen.

1. From the vSphere Client, connect to the vCenter instance.
2. Select the host in the inventory.
3. Click the **Configure** tab.
4. Under System, select **Advanced System Settings**.
5. Select `Annotations.WelcomeMessage`.
6. Click the **Edit** icon.
7. Enter a security message.

The message is displayed on the direct console **Welcome** screen.

Redirecting the Direct Console to a Serial Port

To manage your ESX host remotely from a serial console, you can redirect the direct console to a serial port.

ESX supports the VT100 terminal type and the PuTTy terminal emulator to view the direct console over the serial port.

You can redirect the direct console to a serial port in several ways.

Redirect the Direct Console to a Serial Port by Setting the Boot Options Manually

When you redirect the direct console to a serial port by setting the boot options, the change does not persist for subsequent boots.

Verify that the serial port is not in use for serial logging and debugging.

1. Start the host.
2. When the Loading VMware Hypervisor window appears, press Shift+O to edit boot options.
3. Deactivate the logPort and gdbPort on com1 and set tty2Port to com1 by entering the following boot options:

   ```
   "gdbPort=none logPort=none tty2Port=com1";
   ```

   To use com2 instead, replace `com1` with `com2`.

The direct console is redirected to the serial port until you reboot the host. To redirect the direct console for subsequent boots, see Redirect the Direct Console to a Serial Port from the vSphere Client

Redirect the Direct Console to a Serial Port from the vSphere Client

You can manage the ESX host remotely from a console that is connected to the serial port by redirecting the direct console to either of the serial ports com1 or com2. When you use the vSphere Client to redirect the direct console to a serial port, the boot option that you set persists after subsequent reboots.

- Verify that you can access the host from the vSphere Client.
- Verify that the serial port is not in use for serial logging and debugging, or for ESX Shell (tty1Port).

1. From the vSphere Client, connect to the vCenter instance.
2. Select the host in the inventory.
3. Click the **Configure** tab.
4. Under System, select **Advanced System Settings**.
5. Make sure that the **VMkernel.Boot.logPort** and **VMkernel.Boot.gdbPort** fields are not set to use the com port that you want to redirect the direct console to.
6. Set **VMkernel.Boot.tty2Port** to the serial port to redirect the direct console to: `com1` or `com2`.
7. Reboot the host.

You can now manage the ESX host remotely from a console that is connected to the serial port.

Redirect the Direct Console to a Serial Port in a Host Deployed with Auto Deploy

After you redirect the direct console to a serial port, you can make that setting part of the host profile that persists when you reprovision the host with Auto Deploy.

The serial port must not already be in use for serial logging and debugging.

1. From the vSphere Client, connect to the vCenter instance.
2. Select the host in the inventory.
3. Under System, select **Advanced System Settings**.
4. Make sure that the **VMkernel.Boot.logPort** and **VMkernel.Boot.gdbPort** fields are not set to use the com port that you want to redirect the direct console to.
5. Set **VMkernel.Boot.tty2Port** to the serial port to redirect the direct console to: `com1` or `com2`.
6. Click **OK**.
7. Save the host profile and attach the host to the profile. See the *vSphere Host Profiles* documentation.

The setting to redirect the direct console to a serial port is stored by vCenter and persists when you reprovision the host with Auto Deploy.

Enable ESX Shell and SSH Access with the Direct Console User Interface

Use the direct console user interface to enable the ESX Shell.

1. From the Direct Console User Interface, press F2 to access the System Customization menu.
2. Select **Troubleshooting Options** and press Enter.
3. From the Troubleshooting Mode Options menu, select a service to enable.
   - Enable ESX Shell
   - Enable SSH
4. Press Enter to enable the service.
5. Optional: Set the timeout for the ESX Shell.

   By default, timeouts for the ESX Shell is 0 (not active).

   The availability timeout setting is the number of minutes that can elapse before you must log in after the ESX Shell is enabled. After the timeout period, if you have not logged in, the shell is deactivated.

   Note:
   If you are logged in when the timeout period elapses, your session will persist. However, the ESX Shell is deactivated, preventing other users from logging in.

a) From the Troubleshooting Mode Options menu, select **Modify ESX Shell and SSH timeouts** and press Enter.
b) Enter the availability timeout in minutes.

   The availability timeout is the number of minutes that can elapse before you must log in after the ESX Shell is enabled.
c) Press Enter.
d) Enter the idle timeout.

   The idle timeout is the number of minutes that can elapse before the user is logged out of an idle interactive sessions. Changes to the idle timeout apply the next time a user logs in to the ESX Shell and do not affect existing sessions.

6. Press Esc until you return to the main menu of the Direct Console User Interface.

Set the Password for the Administrator Account

You can use the direct console to set the password for the administrator account (root).

The administrative user name for the ESX host is root. By default, the administrative password is not set.

1. From the direct console, select **Configure Password**.
2. Optional: If a password is already set up, type the password in the **Old Password** line and press Enter.
3. In the **New Password** line, type a new password and press Enter.
4. Retype the new password and press Enter.

Configuring the BIOS Boot Settings

If your server has multiple drives, you might need to configure the BIOS settings.

The BIOS boot configuration determines how your server boots. Generally, the CD-ROM device is listed first.

Note:

If you are using ESX Embedded, the BIOS boot configuration determines whether your server boots into the ESX boot device or another boot device. Generally, the USB flash device is listed first in the BIOS boot settings on the machine that hosts ESX.

When you install or upgrade ESX in UEFI mode, the installer creates a UEFI boot option named VMware ESX and makes it the default boot option, so you do not need to change the boot order.

You can change the boot setting by configuring the boot order in the BIOS during startup or by selecting a boot device from the boot device selection menu. When you change the boot order in the BIOS, the new setting affects all subsequent reboots. When you select a boot device from the boot device selection menu, the selection affects the current boot only.

Some servers do not have a boot device selection menu, in which case you must change the boot order in the BIOS even for one-time boots, and then change it back again during a subsequent reboot.

Change the BIOS Boot Setting for ESX

Configure the BIOS boot setting for ESX if you want the server to boot into ESX by default.

ESX Installable and ESX Embedded cannot exist on the same host.

1. While the ESX host is powering on, press the key required to enter your host's BIOS setup.

   Depending on your server hardware, the key might be a function key or Delete. The option to enter the BIOS setup might be different for your server.
2. Select the BIOS boot setting.

Option	Description
If you are using the installable version of ESX	Select the disk on which you installed the ESX software and move it to the first position in the list. The host boots into ESX .

Option	Description
If you are using ESX Embedded	Select the USB flash device and move it to the first position in the list. The host starts in ESX mode.

Configure the Boot Setting for Virtual Media

If you are using remote management software to set up ESX, you might need to configure the boot setting for virtual media.

ESX Installable and ESX Embedded cannot exist on the same host.

Virtual media is a method of connecting a remote storage media such as CD-ROM, USB mass storage, ISO image, and floppy disk to a target server that can be anywhere on the network. The target server has access to the remote media, and can read from and write to it as if it were physically connected to the server's USB port.

1. Connect the media to the virtual device.
   For example, if you are using a Dell server, log in to the Dell Remote Access Controller (DRAC) or a similar remote management interface and select a physical floppy or CD-ROM drive, or provide a path to a floppy image or CD-ROM image.
2. Reboot the server.
3. While the server is powering on, enter the device selection menu.
   Depending on your server hardware, the key might be a function key or Delete.
4. Follow the instructions to select the virtual device.

The server boots from the configured device once and goes back to the default boot order for subsequent boots. When you install or upgrade ESX in UEFI mode, you do not need to change the boot order, because the system default boot order is set to VMware ESX .

Configuring Network Settings

ESX requires one IP address for the management network. To configure basic network settings, use the vSphere Client or the direct console.

Use the vSphere Client if you are satisfied with the IP address assigned by the DHCP server.

Use the direct console for network configuration in the following cases:

- You are not satisfied with the IP address assigned by the DHCP server.
- You are not allowed to use the IP address assigned by the DHCP server.
- ESX does not have an IP address. This situation might occur if the autoconfiguration phase did not succeed in configuring DHCP.
- The wrong network adapter was selected during the autoconfiguration phase.

Use ESXCLI commands to configure your network settings. See ESXCLI Command Line Reference.

For security considerations, see Securing ESX Hosts.

Network Access to Your ESX Host

The default behavior is to configure the ESX management network using DHCP. You can override the default behavior and use static IP settings for the management network after the installation is completed.

Table 26: Network Configuration Scenarios Supported by ESX

Scenario	Approach
You want to accept the DHCP-configured IP settings.	In the ESX direct console, you can find the IP address assigned through DHCP to the ESX management interface. You can use that IP address to connect to the host from the vSphere Client and customize settings, including changing the management IP address.
One of the following is true: • You do not have a DHCP server. • The ESX host is not connected to a DHCP server. • Your connected DHCP server is not functioning properly.	During the autoconfiguration phase, the software assigns the link local IP address, which is in the subnet 169.254.x.x/16. The assigned IP address appears on the direct console. You can override the link local IP address by configuring a static IP address using the direct console.
The ESX host is connected to a functioning DHCP server, but you do not want to use the DHCP-configured IP address.	During the autoconfiguration phase, the software assigns a DHCP-configured IP address. You can make the initial connection by using the DHCP-configured IP address. Then you can configure a static IP address. If you have physical access to the ESX host, you can override the DHCP-configured IP address by configuring a static IP address using the direct console.
Your security deployment policies do not permit unconfigured hosts to be powered on the network.	Follow the setup procedure in Configure the Network Settings on a Host That Is Not Attached to the Network.

Choose Network Adapters for the Management Network

Traffic between an ESX host and any external management software is transmitted through an Ethernet network adapter on the host. You can use the direct console to choose the network adapters that are used by the management network.

Examples of external management software include the vCenter and SNMP client. Network adapters on the host are named vmnic*N*, where N is a unique number identifying the network adapter, for example, vmnic0, vmnic1, and so forth.

During the autoconfiguration phase, the ESX host chooses vmnic0 for management traffic. You can override the default choice by manually choosing the network adapter that carries management traffic for the host. In some cases, you might want to use a Gigabit Ethernet network adapter for your management traffic. Another way to help ensure availability is to select multiple network adapters. Using multiple network adapters enables load balancing and failover capabilities.

1. From the direct console, select **Configure Management Network** and press Enter.
2. Select **Network Adapters** and press Enter.
3. Select a network adapter and press Enter.

After the network is functional, you can use the vSphere Client to connect to the ESX host through vCenter.

Set the VLAN ID

You can set the virtual LAN (VLAN) ID number of the ESX host.

1. From the direct console, select **Configure Management Network** and press Enter.
2. Select **VLAN** and press Enter.
3. Enter a VLAN ID number from 1 through 4094.

Configuring IP Settings for ESX

By default, DHCP sets the IP address, subnet mask, and default gateway.

For future reference, write down the IP address.

For DHCP to work, your network environment must have a DHCP server. If DHCP is not available, the host assigns the link local IP address, which is in the subnet 169.254.x.x/16. The assigned IP address appears on the direct console. If

you do not have physical monitor access to the host, you can access the direct console using a remote management application. See Using Remote Management Applications.

When you have access to the direct console, you can optionally configure a static network address. The default subnet mask is 255.255.0.0.

Configure IP Settings from the Direct Console

If you have physical access to the host or remote access to the direct console, you can use the direct console to configure the IP address, subnet mask, and default gateway.

1. Select **Configure Management Network** and press Enter.
2. Select **IP Configuration** and press Enter.
3. Select **Set static IP address and network configuration**.
4. Enter the IP address, subnet mask, and default gateway and press Enter.

Configure IP Settings from the vSphere Client

If you do not have physical access to the host, you can use the vSphere Client to configure static IP settings.

1. Log in to the vCenter from the vSphere Client.
2. Select the host in the inventory.
3. On the **Configure** tab, expand **Networking**.
4. Select **VMkernel adapters**.
5. Select **vmk0 Management Network** and click the edit icon.
6. Select **IPv4 settings**.
7. Select **Use static IPv4 settings**.
8. Enter or change the static IPv4 address settings.
9. Optional: Set static IPv6 addresses.
   a) Select **IPv6 settings**.
   b) Select **Static IPv6 addresses**.
   c) Click the add icon.
   d) Type the IPv6 address and click **OK**.
10. Click **OK**.

Configuring DNS for ESX

You can select either manual or automatic DNS configuration of the ESX host.

The default is automatic. For automatic DNS to work, your network environment must have a DHCP server and a DNS server.

In network environments where automatic DNS is not available or not desirable, you can configure static DNS information, including a host name, a primary name server, a secondary name server, and DNS suffixes.

Configure DNS Settings from the Direct Console

If you have physical access to the host or remote access to the direct console, you can use the direct console to configure DNS information.

1. Select **Configure Management Network** and press Enter.
2. Select **DNS Configuration** and press Enter.
3. Select **Use the following DNS server addresses and hostname**.
4. Enter the primary server, an alternative server (optional), and the host name.

Configure DNS Suffixes

If you have physical access to the host, you can use the direct console to configure DNS information. By default, DHCP acquires the DNS suffixes.

1. From the direct console, select **Configure Management Network**.
2. Select **Custom DNS Suffixes** and press Enter.
3. Enter new DNS suffixes.

Configure the Network Settings on a Host That Is Not Attached to the Network

Some highly secure environments do not permit unconfigured hosts on the network to be powered on. You can configure the host before you attach the host to the network.

Verify that no network cables are connected to the host.

1. Power on the host.
2. Use the direct console user interface to configure the password for the administrator account (root).
3. Use the direct console user interface to configure a static IP address.
4. Connect a network cable to the host.
5. Optional: Use the vSphere Client to connect to a vCenter system.
6. Optional: Add the host to the vCenter inventory.

Test the Management Network

You can use the direct console to do simple network connectivity tests.

The direct console performs the following tests.

- Pings the default gateway
- Pings the primary DNS name server
- Pings the secondary DNS nameserver
- Resolves the configured host name

1. From the direct console, select **Test Management Network** and press Enter.
2. Press Enter to start the test.

Restart the Management Agents

The management agents synchronize VMware components and let you access the ESX host by using the vSphere Client and vCenter.

The vSphere Client and vCenter are installed together. You might need to restart the management agents if remote access is interrupted. Restarting the management agents restarts all management agents and services that are installed and running in `/etc/init.d` on the ESX host. Typically, these agents include hostd, ntpd, sfcbd, slpd, wsman, and vobd. The software also restarts the Fault Domain Manager (FDM) if installed.

Users accessing this host by using the vSphere Client and vCenter lose connectivity when you restart management agents.

1. From the direct console, select **Troubleshooting Options** and press Enter.
2. Select **Restart Management Agents** and press Enter.
3. Press F11 to confirm the restart.

The ESX host restarts the management agents and services.

Restart the Management Network

Restarting the management network interface might be required to restore networking or to renew a DHCP lease.

Restarting the management network will result in a brief network outage that might temporarily affect running virtual machines.
If a renewed DHCP lease results in a new network identity (IP address or host name), remote management software will be disconnected.

1. From the direct console, select **Restart Management Network** and press Enter.
2. Press F11 to confirm the restart.

Test Connectivity to Devices and Networks

You can use the direct console to perform some simple network connectivity tests, and specify other devices and networks.

1. From the direct console, select **Test Management Network** and press Enter.
2. Type addresses to ping or another DNS host name to resolve.
3. Press Enter to start the test.

Restoring the Standard Switch

A vSphere Distributed Switch functions as a single virtual switch across all associated hosts.

Verify that your management network is connected to a distributed switch.

Virtual machines can maintain a consistent network configuration as they migrate across multiple hosts. If you migrate an existing standard switch, or virtual adapter, to a Distributed Switch and the Distributed Switch becomes unnecessary or stops functioning, you can restore the standard switch to ensure that the host remains accessible.When you restore the standard switch, a new virtual adapter is created and the management network uplink that is currently connected to Distributed Switch is migrated to the new virtual switch.
You might need to restore the standard switch for the following reasons:

- The Distributed Switch is not needed or is not functioning.
- The Distributed Switch needs to be repaired to restore connectivity to vCenter and the hosts need to remain accessible.
- You do not want vCenter to manage the host. When the host is not connected to vCenter, most Distributed Switch features are unavailable to the host.

1. From the direct console, select **Restore Standard Switch** and press Enter.
   If the host is on a standard switch, this selection is dimmed, and you cannot select it.
2. Press F11 to confirm.

Configuring System Logging

ESX hosts run the syslog service (`vmsyslogd`) that writes messages from system components to log files and can forward messages to syslog collectors.

You can configure the amount and location of the logs. You can also create and apply log filters to modify the logging policy of an ESX host.

When configuring remote hosts for syslog, you also need to open some specified ports in the ESX host firewall to allow the transmission of log messages. For more information, see Broadcom knowledge base article 312032.

Configure Syslog on ESX Hosts

You can use the vSphere Client, the VMware Host Client, or the `esxcli system syslog` command to configure the syslog service.

The syslog service receives, categorizes, and stores log messages for analyses that help you take preventive action in your environment.

For information about using the `esxcli system syslog` command and other ESXCLI commands, see ESXCLI Command Line Reference. For details how to open the ESX firewall for the port specified in each remote host specification, see the vSphere Security guide.

Set ESX Syslog by using the vSphere Client

You can use the command to configure the syslog service globally and edit various advanced settings:

1. Browse to the host in the inventory.
2. Click **Configure**.
3. Under **System**, click **Advanced System Settings**.
4. Click **Edit**.
5. Filter for *syslog*.
6. To set up logging globally and configure various advanced settings, see ESX Syslog Options.
7. To overwrite the default log size and log rotation for any of the logs:
   a. Click the name of the log that you want to customize.
   b. Enter the number of rotations and the log size you want.
8. Click **OK**.

Syslog parameter settings that you define by using the vSphere Client or VMware Host Client are effective immediately. However, most settings you define by using ESXCLI require an additional command to take effect. For more details, see ESX Syslog Options.

Set ESX Syslog by using the VMware Host Client

You can use the VMware Host Client to configure and edit syslog service parameters on hosts.

1. In the VMware Host Client, under **Host**, click **Manage > System > Advanced settings**.
2. In the **Search** panel, type a syslog setting you want to define. See ESX Syslog Options.
3. Select the setting and click **Edit option**.
4. Set the value as described in the table of parameters in ESX Syslog Options.
5. Click **Save**.

Set ESX Syslog by using ESXCLI

You can configure the syslog service on hosts by using the ESXCLI command: `esxcli system syslog config set <syslog option>`.

For information about using the `esxcli system syslog` command and other ESXCLI commands, See the ESXCLI Command Line Reference on the Broadcom Developer Portal. For details how to open the firewall for the port specified in each remote host specification, see Configuring the ESX Firewall in the vSphere Security guide.

Using ESXCLI requires ESX to open SSH logins, which is a security risk, and is not recommended. If you chose to use ESXCLI, make sure you use the `esxcli system syslog reload` command after setting each parameter to make sure that it takes effect.

1. Use the ESXCLI command `esxcli system syslog config set <syslog option>` to set a syslog option that you decide to enable. For example, to set the `Syslog.global.logHost` option, use the command `esxcli system syslog config set --loghost=<str>`
2. After setting `Syslog.global.logHost`, ESX hosts open and maintain connections to the syslog collectors, and the transmission of messages begins immediately. When ESX generates a syslog message, it writes it to the appropriate log file on the ESX host and also forwards it to all configured syslog collectors.

Fine-tune Syslog on ESX Hosts

By using the right syslog settings, you can achieve proactive monitoring of your environment, reduce downtime, and take preventive action on servers.

While setting up syslog, you need to consider several parameters that affect log file retention, syslog transmission, transmission length, error handling, and the set up of SSL certificates for secure syslog message transmission. What follows are recommendations for fine-tuning your syslog parameters. You can see a description of all available parameters at ESX Syslog Options.

How to Specify Log File Retention

By default, log files cannot expand past a configured size. Once a log file reaches the configured size, logging is routed to a new log file and the oldest log file is deleted.

> **Note:**
> Best practice is to balance the rotate and size settings. Increasing the rotate setting ensures that syslog files are generated often enough to prevent any potential corruption or destruction from the other log files. Increasing the size setting reduces the time for switching to another log file. Optimal size settings are a multiple of 1024 KiB.

Use the Syslog.global.defaultSize setting to specify the log file maximum size in KiB, and Syslog.global.defaultRotate to set the maximum number of old log files to keep before rotating to a new log file. To change the log file retention parameters associated with a specific program, use the `Syslog.loggers.<progName>.rotate` and `Syslog.loggers.<progName>.size settings`, where `<progName>` is the name of the program whose parameters you want to adjust.

Manage Settings that Affect the Virtual Machine Log File

You can configure some settings that affect the virtual machine log file, `vmware.log`, either in the `vmx` file or in the `/etc/vmware/config` file. You must power off a virtual machine to edit the `vmx` file and edits take effect only on that virtual machine. If you use the `/etc/vmware/config` file, you must add the prefix *`"vmx"`* to the setting, for example `vmx.log.keepOld = "20"`, and edits affect all virtual machines on the ESX host.

Table 27: Configurable settings for the vmware.log file

Parameter	Description	Example	Notes
`logging`	Disables all virtual machine logging.	The default value is `logging = "TRUE"` To disable virtual machine logging: `logging = "FALSE"`	Do not use this setting, because disabling virtual machine logging makes it difficult or impossible to get support for virtual machine problems. If you need to use this setting for some reason, you can only place it in the `vmx` file of a virtual machine.
`log.throttleBytesPerSec`	Controls when a log file throttles. Log file throttling occurs when writes to the `vmware.log` exceed the specified rate for a significant amount of time. This occurs when code within the VMX process, which controls a virtual machine, creates excessive log messages. The default value for this setting is 1 KB/sec. In case of log thottling, you see `<<< Log Throttled >>>` in the `vmware.log` file.	`log.throttleBytesPerSec = "1500"` To disable log throttling, use `log.throttleBytesPerSec = "0xFFFFFFFF"`	Log file thottling might obscure information necessary to diagnose problems with the affected virtual machine. If you need to disable log throttling, place the line in the example in the `vmx` file of the affected virtual machine. Remove the line after the debugging session ends.

Parameter	Description	Example	Notes
log.keepOld	Controls the number of older vmware.log file to retain.	log.keepOld = "20"	Do not put the value of this setting below the default value (10). If virtual machines are frequently modified or moved, consider raising this setting to 20 or more.
log.rotateSize	Controls the maximum size of a vmware.log file in bytes.	log.rotateSize = "2500000" To disable limiting the maximum size of a vmware.log file, use log.rotateSize = "0"	A value of this setting below 100,000 can cause a loss of critical log messages and affect virtual machine performance. In ESX 7.x and earlier, the default value of this setting places no limit on the size of a vmware.log file. In ESX 8.x and later, the default value of this setting is 2,048,000.
log.fileName	Controls the name and location of virtual machine log files.	log.fileName = "myVMLog" This setting changes the name of the virtual machine log files from vmware.log to myVMlog. log.fileName = "/vmfs/volumes/vol1/myVM/myVM.log" This setting directs virtual machine log files to a directory on a different VMFS volume (vol1) by using myVM for a file name.	Do not place a log file outside the virtual machine directory to make sure that the collection of host support bundles picks up the log file, which can be critical to debug virtual machine problems.
log.fileLevel	Controls the minimum level at which messages are written to vmware.log. Every log message has a level associated with it. Levels below the specified setting are not added to a virtual machine log file. The virtual machine message log levels (from most to least restricted) are: • error • warning • notice • info (default) • trivia • debug • debug1 • debug2 • debug3 • debug4 • debug5 • debug6 • debug7 • debug8 • debug9 • debug10	log.fileLevel = "debug1"	Do not set a more restrictive level than "info" to avoid filtering out messages that are necessary for debugging virtual machine problems. Lower the level below "info" only upon request by licensed support. Restore the setting to "info" after debugging ends.

Parameter	Description	Example	Notes
`log.filter.minLogLevel.<groupName>`	Controls the output of specialized debugging messages.	`log.filter.minLogLevel.vsish = "debug5"`	Use this setting only upon request by licensed support, who should provide one or more `<groupName>` parameters. Remove the setting after debugging ends.
`log.sysogID`	Activates the sending of virtual machine log messages to the system logger of an ESX host, such as the syslog.	`log.syslogID = "vmx"`	Use `"vmx"` as value for this setting to allow the ESX syslog daemon, `vmsyslogd`, to send these messages to a separate log file.
`log.syslogLevel`	Controls the minimum level at which messages are output to the system logger of an ESX host, such as the syslog.	`log.syslogLevel = "debug"`	The levels and functioning of this setting are identical to those for the `log.fileLevel` setting.

How to Specify Message Transmission to Remote Hosts

Optionally, you can configure ESX to send syslog messages to one or more remote hosts, called syslog collectors, such as VCF Operations Log Management (formerly VCF Operations for Logs,VMware vRealize Log Insight, and vCenter Log Insight), to collect syslog messages.

Note:

Best practice is that you configure each ESX host to send syslog messages to at least one syslog collector. This helps ensure that the messages are preserved in case of a catastrophic system event and that you can process syslog messages in various ways, such as real-time categorization and analysis (for example, by type, time span, or machine), or archive messages.

Use the `Syslog.global.logHost` setting to define remote host specifications. Separate multiple remote host specifications with a comma (,). After setting `Syslog.global.logHost`, ESX hosts open and maintain connections to the syslog collectors, and the transmission of messages begins immediately. When ESX generates a syslog message, it writes it to the appropriate log file on the ESX host and also forwards it to all configured syslog collectors.

In addition to syslog messages, audit messages can also be transmitted to syslog collectors for security purposes. Audit records track security-related activity on the ESX host. For more information about audit records, see Log File Formats.

Note:
Consult with your company security response team if and how to set audit records. Certified configurations usually require audit records to be activated.

What follows is the syntax for `Syslog.global.logHost` remote host specifications:

`protocol://target[:port][?formatter=value[&framing=value]]`

Parameter	Description	Notes
`protocol`	Specifies the networking protocol. Valid values are `udp`, `tcp`, and `ssl`.	The `ssl` protocol specifies that transmission of syslog messages is encrypted. The `tcp` and `udp` protocols do not encrypt the transmission. **Note:** If capturing syslog messages or audit messages is critical to your system, avoid using the `udp` protocol because the networking infrastructure external to ESX might drop UDP messages.
`target`	Specifies the remote host. You can use either an IPV4 or IPV6 address, or a host name.	When you use an IPV6 address, you must embed it in square brackets `[xxx]`, where `xxx` is the IPV6 address.
`port`	(Optional) Specifies the remote host port to use. If you use UDP or TCP, the default port is 514. If you use SSL, the default port is 1514. If you choose to use different ports from 514 or 1514, you must adjust the ESX firewall to open the port.	For details how to open the ESX firewall for the port specified in each remote host specification, see the topic about *configuring the ESX firewall* in the *vSphere Security* guide.
`formatter`	Specifies how transmissions are formatted. The formatter must be RFC 3164 or RFC 5424.	RFC 3164 is the default.
`framing`	Specifies if transmissions are framed. Framing must be `non_transparent` or `octet_counting`.	The default is `non_transparent`. Transmissions in RFC 5424 format must specify `octet_counting` framing. For more information, see Protocols, Formats, and Framing of ESX Syslog Messages.

Examples of remote machine specifications:

Syslog.global.logHost string example	Notes
tcp://10.176.130.7:12345?formatter=RFC_3164	Transmits syslog messages to 10.176.130.7 using TCP/IP and port 12345. Transmission format is RFC 3164 with no framing.
tcp://10.176.130.7:12345?formatter=RFC_3164&framing=octet_counting	Transmits syslog messages to 10.176.130.7 using TCP/IP and port 12345. Transmission format is RFC 3164 and framing is `octet_counting`.
tcp://10.176.130.7:12345?formatter=RFC_5424&framing=octet_counting	Transmits syslog messages to 10.176.130.7 using TCP/IP and port 12345. Transmission format is RFC 5424 and framing is `octet_counting`.
tcp://[2001:db8:85a3:8d3:1319:8a2e:370:7348]	Transmits syslog messages to an IPV6 address using port 1514.
tcp://[2001:db8:85a3:8d3:1319:8a2e:370:7348]:5432	Transmit syslog messages to an IPV6 address using port 54321.
udp://company.com	Transmits syslog messages to `company.com` using UDP and port 514.
udp://company.com,tcp://10.20.30.40:1050	Transmits syslog messages to two remote hosts. The first remote host uses UDP to communicate with `company.com` using port 514. The second remote host uses TCP to communicate with the IPV4 address `10.20.30.40` using port 1050.
ssl://company.com	Transmits syslog messages to `company.com` using SSL (TLS) and port 514.

Maximum Message Transmission Length

If you use UDP, the maximum syslog message transmission length is 480 bytes for IPV4 and 1180 bytes for IPV6.

For TCP or SSL, the default maximum syslog message transmission length is 1 kibibyte (KiB). You can increase this length by using the `Syslog.global.remoteHost.maxMsgLen` parameter. The maximum value is 16 KiB. Messages longer than 16 KiB are truncated.

> **Note:**
> If increasing the maximum transmission length is necessary, best practice is to increase the length only as much as specifically necessary.

Increasing the maximum syslog message length can cause problems if the networking and syslog infrastructure external to ESX is unable to handle messages longer than 1 KiB.

> **Note:**
> Best practice is that you do not use UDP to transmit syslog messages due to the packet length constraints and the possibility that the external networking infrastructure might drop the messages.

Considerations for Certificates When Configuring SSL Transmissions to Remote Hosts

When configuring ESX to transmit syslog messages to remote hosts using SSL, you must add an SSL certificate for each remote host to the ESX host CA store. For more information, see the topic about managing certificates for ESX hosts in the *vSphere Security* guide.

> **Note:**
> Consult with your syslog collector documentation on how to configure the collector for secure receipt of syslog messages using SSL and a private key.

Additional SSL Transmission Parameters

An ESX system complying with security certification requirements might require activating X509 CRL checks.
You turn on the advanced settings `Syslog.global.certificate.strictX509Compliance` and `Syslog.global.certificate.checkCRL` by changing the default value of `false` to `true`. Due to implementation limitations, if you activate CRL checks by using the setting `Syslog.global.certificate.checkSSLCerts`, then all certificates in a certificate chain must provide a CRL link. By default, the setting is active. You can deactivate SSL certificate checks by changing the setting to `false`, but this is not a best practice. You might need to turn off SSL certificate checks when troubleshooting communications with a remote host, but do this only for a limited time.

Where to Find Syslog Daemon Error and Status Information

The ESX syslog daemon uses the log file `/var/run/log/vmsyslogd.log` to store status and error information, including dropped messages. If audit record transmission is active, the syslog daemon also emits audit records related to its operation, such as daemon start, stop, and error conditions, which allows you to verify that the syslog daemon runs properly.

How to Change the Default Syslog Log File Storage Area

The default syslog log file storage area is `/var/run/log`, local to each ESX host. Use the `Syslog.global.logDir` syslog configuration variable to change the default syslog log file storage area, as long as the location resides on persistent storage. If `Syslog.global.logDir` is configured to a persistent store shared by multiple ESX hosts to store their syslog log files, change the `Syslog.global.logDirUnique` setting to `true` to prevent mixing logs. The `Syslog.global.logDirUnique` setting makes sure that each ESX machine a unique name added to the `Syslog.global.logDir` path, separating the log files from other hosts.

Syslog Message Queueing for Remote Hosts and Message Drops

Once syslog emissions start, they never stop except for ESX reboots and failures, or a syslog reconfiguration to stop.

To avoid dropping messages, ESX uses an in-memory queue that allows the `vmsyslogd` service to handle the following conditions for a short time:

- ESX generates log messages at a faster rate than the `vmsyslogd` service can process and transmit
- Network connectivity between ESX and the remote host fails

If either of these conditions continues for a long period, the capacity of the in-memory queue might not be sufficient and `vmsyslog` might stop transmitting messages and audit logs to remote hosts. No data is lost, because dropped messages are written to the `/var/run/log/vmsyslogd-dropped.log` file.

To minimize the chance that message dropping occurs, place the `vmsyslogd` log files on the fastest available storage and configure `vmsyslogd` and its syslog collectors on a network with end-to-end bandwidth greater than 1 GigE.

> **Note:**
> Consider an end-to-end bandwidth of 2.5 GigE or more, preferably 10 GigE, to optimize performance and prevent message drops.

If you see excessive logs from an application, file a support service request for analysis and correction.

You can see statistics about message drops in the syslog daemon log file.

You can see dropped messages at `/var/run/log/vmsyslogd-dropped.log`. This log file has retention settings specific to it, similar to those for the program-specific retention parameters. The dropped messages log file retention parameters are: `Syslog.global.droppedMsgs.fileRotate` and `Syslog.global.droppedMsgs.fileSize`.

ESX Syslog Options

You can define the behavior of ESX syslog files and transmissions by using a set of syslog options.

Apart from the base settings, such as `Syslog.global.logHost`, starting from ESX 7.0 Update 1, a list of advanced options is available for customizations, and NIAP compliance.

> **Note:**
> Always configure persistent storage before you set any of the audit record parameters or the `Syslog.global.logDir` parameter.

> **Note:**
> All audit record settings, beginning with `Syslog.global.auditRecord`, take effect immediately. However, for other settings that you define by using ESXCLI, make sure to run the `esxcli system syslog reload` command to enable the changes.

Table 28: Legacy Syslog Options

Option	ESXCLI command	Description
`Syslog.global.logHost`	`esxcli system syslog config set --loghost=<str>`	Defines a comma-delimited list of remote hosts and specifications for message transmissions. If the `loghost=<str>` field is blank, no logs are forwarded. While no hard limit to the number of remote hosts to receive syslog messages exists, good practice is to keep the number of remote hosts to five or less. The format of a remote host specification is: `protocol://hostname|ipv4|'['ipv6']'[:port]`. The protocol must be one of TCP, UDP, or SSL. The value of a port can be any decimal number from 1 through 65535. If a port is not provided, SSL and TCP use 1514. UDP uses 514. For example: `ssl://hostName1:1514`.
`Syslog.global.defaultRotate`	`esxcli system syslog config set --default-rotate=<long>`	Maximum number of old log files to keep. You can set this number globally and for individual subloggers (see `Syslog.global.defaultSize`).

Option	ESXCLI command	Description
Syslog.global.defaultSize	esxcli system syslog config set --default-size=<long>	Default size of log files, in KiB. After a file reaches the default size, the syslog service creates a new file. You can set this number globally and for individual subloggers.
Syslog.global.logDir	esxcli system syslog config set --logdir=<str>	Directory where logs reside. The directory can be on mounted NFS or VMFS volumes. Only the /scratch directory on the local file system is persistent across reboots. Specify the directory as [*datastorename*] *path_to_file*, where the path is relative to the root of the volume backing the datastore. For example, the path [storage1] /systemlogs maps to the path /vmfs/volumes/storage1/systemlogs.
Syslog.global.logDirUnique	esxcli system syslog config set --logdir-unique=<bool>	Specifies the ESX host name to be concatenated to the value of Syslog.global.logDir. It is critical that you enable this setting when multiple ESX hosts log to a shared file system. Selecting this option creates a subdirectory with the name of the ESX host under the directory specified by **Syslog.global.LogDir**. A unique directory is useful if the same NFS directory is used by multiple ESX hosts.
Syslog.global.certificate.checkSSLCerts	esxcli system syslog config set --check-ssl-certs=<bool>	Enforces checking of SSL certificates when transmitting messages to remote hosts.

Table 29: Syslog Options Available Starting from ESX 7.0 Update 1 and later

Option	ESXCLI command	Description
Syslog.global.auditRecord.storageCapacity	esxcli system auditrecords local set --size=<long>	Specifies the capacity of the audit record storage directory located on the ESX host, in MiB. You cannot decrease the capacity of the audit record storage. You can increase the capacity before or after the audit record storage is enabled (see Syslog.global.auditRecord.storageEnable).
Syslog.global.auditRecord.remoteEnable	esxcli system auditrecords remote enable	Enables sending audit records to remote hosts. Remote hosts are specified by using the Syslog.global.logHost parameter.
Syslog.global.auditRecord.storageDirectory	esxcli system auditrecords local set --directory=<dir>	Creates an audit record storage directory and unless specified, sets /scratch/auditLog as the default location. You must not manually create an audit record storage directory and you cannot change the audit record storage directory while audit record storage is enabled (see Syslog.global.auditRecord.storageEnable).
Syslog.global.auditRecord.storageEnable	esxcli system auditrecords local enable	Enables the storage of audit records on an ESX host. If the audit record storage directory does not exist, it is created with the capacity specified by Syslog.global.auditRecord.storageCapacity.

Option	ESXCLI command	Description
`Syslog.global.certificate.checkCRL`	`esxcli system syslog config set --crl-check=<bool>`	Enables checking the revocation status of all the certificates in an SSL certificate chain. Enables verification of X.509 CRLs, which are not checked by default in compliance with industry conventions. A NIAP-validated configuration requires CRL checks. Due to implementation limitations, if CRL checks are enabled, then all certificates in a certificate chain must provide a CRL link. Do not enable the `crl-check` option for installations not related to certification, because of the difficulty in properly configuring an environment that uses CRL checks.
`Syslog.global.certificate.strictX509Compliance`	`esxcli system syslog config set --x509-strict=<bool>`	Enables strict compliance with X.509. Performs additional validity checks on CA root certificates during verification. These checks are generally not performed, as CA roots are inherently trusted, and might cause incompatibilities with existing, misconfigured CA roots. A NIAP-validated configuration requires even CA roots to pass validations. Do not enable the `x509-strict` option for installations not related to certification, because of the difficulty in properly configuring an environment that uses CRL checks.
`Syslog.global.droppedMsgs.fileRotate`	`esxcli system syslog config set --drop-log-rotate=<long>`	Specifies the number of old dropped message log files to keep.
`Syslog.global.droppedMsgs.fileSize`	`esxcli system syslog config set --drop-log-size=<long>`	Specifies the size of each dropped message log file before switching to a new one, in KiB.
`Syslog.global.logCheckSSLCerts`	`esxcli system syslog config set --check-ssl-certs=<bool>`	Enforces checking of SSL certificates when transmitting messages to remote hosts. **Note:** Deprecated. Use `Syslog.global.certificate.checkSSLCerts` in ESX 7.0 Update 1 and later.

Option	ESXCLI command	Description
`Syslog.global.logFilters`	`esxcli system syslog config logfilter [add | remove | set] ...`	Specifies one or more log filtering specifications. Each log filter must be separated by a double vertical bar "||". The format of a log filter is: `numLogs | ident | logRegexp`. `numLogs`sets the maximum number of log entries for the specified log messages. After reaching this number, the specified log messages are filtered and ignored. `ident` specifies one or more system components to apply the filter to the log messages that these components generate. `logRegexp` specifies a case-sensitive phrase with Python regular expression syntax to filter the log messages by their content.
`Syslog.global.logFiltersEnable`		Enables the use of log filters.
`Syslog.global.logLevel`	`esxcli system syslog config set --log-level=<str>`	Specifies the log filtering level. You must change this parameter only when troubleshooting an issue with the syslog daemon. You can use the values `debug` for the most detailed level, `info` for the default detail level, `warning` for only warnings or errors, or `error`, only for errors.
`Syslog.global.msgQueueDropMark`	`esxcli system syslog config --queue-drop-mark=<long>)`	Specifies the percent of the message queue capacity at which messages are dropped.
`Syslog.global.remoteHost.connectRetryDelay`	`esxcli system syslog config set --default-timeout=<long>`	Specifies the delay before retrying to connect to a remote host after a connection attempt fails, in seconds.
`Syslog.global.remoteHost.maxMsgLen`	`esxcli system syslog config set --remote-host-max-msg-len=<long>`	Specifies the maximum length of a syslog transmission before truncation occurs, in bytes. The default maximum length for remote host messages is 1 KiB for TCP, SSL, and UDP protocols. You can increase the maximum message length to up to 16 KiB. However, raising this value above 1 KiB does not ensure that long transmissions arrive untruncated to a syslog collector. For example, when the syslog infrastructure that issues a message is external to ESX. For versions earlier than ESXi 8.0 Update 3i, this parameter applies only to TCP and SSL protocols. UDP maximum message transmission length is limited at 480 bytes for IPV4 and 1180 bytes for IPV6.
`Syslog.global.vsanBacking`	`esxcli system syslog config set --vsan-backing=<bool>`	Allows log files and the audit record storage directory to be placed on a vSAN cluster. However, enabling this parameter might cause the ESX host to become unresponsive.

Protocols, Formats, and Framing of ESX Syslog Messages

Starting with ESX 8.0, the ESX syslog daemon, vmsyslogd, uses three parameters to define how to send messages and audit records - protocol, formatting, and framing.

The supported protocols are UDP, TCP, and TLS (SSL). Formatting of syslog messages is defined by either RFC 3164 or RFC 5424. Framing specifies how a message is encapsulated. Framing of encapsulated messages is defined as transparent, also called octet_counting, or non-transparent, if a message is not encapsulated. Transparent framing ensures that new lines embedded in a message do not confuse a syslog collector. Syslog messages sent by using the UDP protocol are considered transparently framed; a syslog collector is expected to understand this and accept the transmission as a single message.

RFC 3164 sets the maximum total length of a syslog message at 1024 bytes, while RFC 5424 extends this maximum to 2048 bytes.

The default maximum length for remote host messages in ESX is 1 KiB. You can increase the maximum message length to up to 16 KiB. However, raising this value above 1 KiB does not ensure that long transmissions arrive untruncated to a syslog collector. For example, when the syslog infrastructure that issues a message is external to ESX.

Syslog messages that the vmsyslogd transmits consist of structured data, a property list formatted in compliance with RFC 5424, and free format, or unstructured, data.

When a message is longer than the maximum length, ESX 8.0 and later mitigates the message, trying to preserve as much of the structured data as possible.

When a message is mitigated, three parameters are either added to existing structured data or structured data is created to contain these parameters: `msgModified`, `remoteHostMaxMsgLen`, and `originalLen` .

The `msgModified` parameter indicates how the mitigation impacts the message: only structured data, only unstructured data, or both.

The `remoteHostMaxMsgLen` parameter specifies the maximum message length that ESX can handle.

The `originalLen` parameter specifies the message length before it is mitigated.

Supported options for protocols, formatting, and framing of ESX syslog messages:

Formatting	Framing	UDP	TCP	SSL	Comments
Unspecified	Unspecified	Supported RFC 5426	Supported	Supported	Formatting of messages complies to RFC 3164, only timestamps are in RFC 3339 format. Structured data is prepended to each message. Framing defaults to non-transparent with TCP or SSL (TLS) and embedded newlines in structured data might corrupt messages. With UDP, packets are framed.
Unspecified	Non_transparent	Forbidden	Supported	Supported	Formatting of messages complies to RFC 3164, only timestamps are in RFC 3339 format. Structured data is prepended to each message. Framing defaults to non-transparent with TCP or SSL (TLS) and embedded newlines in structured data might corrupt messages.
Unspecified	Octet_counting	Forbidden	Supported RFC 6587	Supported RFC 6587	Formatting of messages complies to RFC 3164, only timestamps are in RFC 3339 format. Structured data is prepended to each message.

Formatting	Framing	UDP	TCP	SSL	Comments
RFC 5424	Unspecified	Supported RFC 5426	Supported RFC 5425	Supported RFC 5424	Formatting of messages complies to RFC 5424. Framing defaults to octet-counting with TCP or SSL (TLS). With UDP, framing might not be explicitly specified.
RFC 5424	Non_transparent	Forbidden	Not Supported	Not Supported	Not supported because embedded newlines in structured data might create corrupted messages.
RFC 5424	Octet_counting	Forbidden	Supported RFC 5425	Supported RFC 5425	Formatting of messages complies to RFC 5424.
RFC 3164	Unspecified	Supported RFC 5426	Supported	Supported	Formatting of messages complies to RFC 3164, only timestamps are in RFC 3339 format. Structured data is prepended to each message. Framing defaults to non-transparent with TCP or SSL (TLS) and embedded newlines in structured data might corrupt messages. With UDP, packets are framed.
RFC 3164	Non_transparent	Forbidden	Supported	Supported	Formatting of messages complies to RFC 3164, only timestamps are in RFC 3339 format. Structured data is prepended to each message. Framing defaults to non-transparent with TCP or SSL (TLS) and embedded newlines in structured data might corrupt messages.
RFC 3164	Octet_counting	Forbidden	Supported RFC 6587	Supported RFC 6587	Formatting of messages complies to RFC 3164, only timestamps are in RFC 3339 format. Structured data is prepended to each message.

Log File Formats

Starting with ESX 8.0, the format of log files is standardized and is expressed in Augmented Backus-Naur Form (ABNF).

In ESX 8.0 and later, log files are written either directly, from a single service such as VMX, or indirectly, when logs from a service are submitted to a syslog. For example, VMX always writes log messages in the `vmware.log` file of each virtual machine. To spare system resources, VMX does not submit log messages to the syslog. On the other hand, in some log files that `vmsyslogd` generates, you see messages from multiple programs, because the ESX syslog daemon creates and manages all log files, and messages to these files, from multiple services.

Format for direct log messages:

Parameter	Value
`LOG-MSG`	HEADER SP MSG
`HEADER`	TIMESTAMP SP SEVERITY SP THREAD-NAME SP OPID
`TIMESTAMP`	FULL-DATE T FULL-TIME (Complies to RFC 5424 with the requirement for UTC/GMT formatting and resolution in milliseconds, or more granular where possible.)
`FULL-DATE`	DATE-FULLYEAR - DATE-MONTH - DATE-MDAY
`DATE-FULLYEAR`	4DIGIT

DATE-MONTH	2DIGIT ; 01-12
DATE-MDAY	2DIGIT ; 01-28, 01-29, 01-30, 01-31 based on month/year
FULL-TIME	TIME-HOUR : TIME-MINUTE : TIME-SECOND[TIME-SECFRAC] Z
TIME-HOUR	2DIGIT ; 00-23
TIME-MINUTE	2DIGIT ; 00-59
TIME-SECOND	2DIGIT ; 00-59
TIME-SECFRAC	'.' 1*6DIGIT
SEVERITY	SEVERITY-STRING SEVERITY-VALUE [LINE-MARKER]
SEVERITY-STRING	Em/ Al / Cr / Er / Wa / No / In / Db (The 8 severity levels specified in RFC 5424 are abbreviated as follows: • Em - Emergency • Al - Alert • Cr - Critical • Er - Error • Wa - Warning • No - Notice • In - Informational • Db - Debug
SEVERITY-VALUE	(*DIGIT) (The SEVERITY-VALUE is an optional expression of the numeric value associated with the SEVERITY-STRING. This allows levels supported by a logger to be collapsed into the 8 required strings with no loss of information (e.g. Db(5) - debug, level 5).)
LINE-MARKER	+ (The LINE-MARKER is added to each subsequent line generated from a multi-line submission. It identifies multiline submissions and prevents a log injection security attack.)
NILVALUE	- (A single threaded program might not have a thread name and NILVALUE is acceptable.)
THREAD-NAME	NILVALUE / 1*32PRINTUSASCII (The component (APP-NAME) is implied when a single program writes the file and no component field is necessary, only the thread name.)
OPID	NILVALUE / 1*128UTF-8-STRING
STRUCTURED-DATA	1*SD-ELEMENT
SD-ELEMENT	[SD-ID *(SP SD-PARAM)]
SD-PARAM	PARAM-NAME %d34 PARAM-VALUE %d34
SD-ID	SD-NAME
PARAM-NAME	SD-NAME
PARAM-VALUE	UTF-8-STRING ; characters '', '\' and ']' MUST be escaped.
SD-NAME	1*32PRINTUSASCII ; except '', SP, ']', %d34 ()
MSG	[STRUCTURED-DATA SP] UTF-8-STRING

Format for log files that the vmsyslogd service manages:

Parameter	Value
LOG-MSG	HEADER SP MSG
HEADER	TIMESTAMP SP SEVERITY SP APP-NAME [PROC-IDENTIFIER] :
APP-NAME	1*32PRINTUSASCII
PROC-IDENTIFIER	[*DIGITS] ; the PID associated with APP-NAME
TIMESTAMP	FULL-DATE T FULL TIME (resolution in milliseconds or more granular where possible.)
FULL-DATE	DATE-FULLYEAR - DATE-MONTH - DATE-MDAY
DATE-FULLYEAR	4DIGIT

DATE-MONTH	2DIGIT ; 01-12
DATE-MDAY	2DIGIT ; 01-28, 01-29, 01-30, 01-31 based on month/year
FULL-TIME	TIME-HOUR : TIME-MINUTE : TIME-SECOND[TIME-SECFRAC] Z
TIME-HOUR	2DIGIT ; 00-23
TIME-MINUTE	2DIGIT ; 00-59
TIME-SECOND	2DIGIT ; 00-59
TIME-SECFRAC	'.' 1*6DIGIT
SEVERITY-STRING	Em/ Al / Cr / Er / Wa / No / In / Db (The 8 severity levels specified in RFC 5424 are abbreviated as follows: • Em - Emergency • Al - Alert • Cr - Critical • Er - Error • Wa - Warning • No - Notice • In - Informational • Db - Debug
SEVERITY	SEVERITY-STRING PRI-STRING [LINE-MARKER]
PRIVAL	1*3DIGIT ; range 0 .. 191 (the MSG PRI; contains facility and severity values, ORed together)
PRI-STRING	(PRIVAL) (The PRIVAL contains the bits from the message PRI. This allows one to see the Facility of the message, as well as the severity bits themselves._
LINE-MARKER	+ (The LINE-MARKER is added to each subsequent line generated from a multi-line submission. It identifies multiline submissions and prevents a log injection security attack.)
STRUCTURED-DATA	1*SD-ELEMENT
SD-ELEMENT	[SD-ID *(SP SD-PARAM)]
SD-PARAM	PARAM-NAME %d34 PARAM-VALUE %d34
SD-ID	SD-NAME
PARAM-NAME	SD-NAME
PARAM-VALUE	UTF-8-STRING ; characters '', '\' and ']' MUST be escaped.
SD-NAME	1*32PRINTUSASCII ; except '', SP, ']', %d34 ()
MSG	[STRUCTURED-DATA SP] UTF-8-STRING

Audit Records

ESX audit records, with facility code 13, are compliant to both RFC 3164 and 5424 formats and you find them in the structured data section. In the audit record, you also find event-based traceability information when such data is available. Audit records are stored in a special format, not in a regular log file. You can access audit records locally by using the viewAudit program and the Virtual Infrastructure Management functionality FetchAuditRecords. Do not read, use, or edit an audit record storage file directly. Locally stored audit records comply with RFC 5424 transmission format where the HOSTNAME and MSGID are always NILVALUE.

ESX Syslog Message Transmission Formats

ESX 8.0 and later formats syslog messages in compliance with either RFC 3164 or RFC 5424.

> **Note:**
> The timestamps associated with RFC 3164 messages are in RFC 3339 format, an exception to the RFC 3164 specification.

The definition of the ESX transmission formats for RFC 3164 and RFC 5424 is in Augmented Backus-Naur Form (ABNF).

RFC 3164 Transmission Message Format

Parameter	Value
SYSLOG-MSG	HEADER SP MSG
HEADER	PRI TIMESTAMP SP HOSTNAME SP APP-NAME [PROC-IDENTIFIER] ":"
PRI	"<" PRIVAL ">"
PRIVAL	1*3DIGIT ; range 0 .. 191 (the MSG PRI; contains facility and severity values, ORed together)
APP-NAME	1*32PRINTUSASCII

Configure Log Filtering on ESX Hosts

The log filtering capability lets you modify the logging policy of the syslog service that is running on an ESX host.

You can create log filters to reduce the number of repetitive entries in the ESX logs and to denylist specific log events entirely.

Install ESXCLI. See *Getting Started with ESXCLI*. For troubleshooting, run `esxcli` commands in the ESX Shell.

You can add log filters and enable log filtering by using ESXCLI. A log filter, once established, remains in place until it is removed, even across ESX reboots.

Log filters affect all log events that are processed by the ESX host `vmsyslogd` service, whether they are recorded to a log directory or to a remote syslog server.

You must enable the log filtering capability and reload the syslog daemon to activate the log filters on the ESX host.

ESXCLI commands to configure log filters follow this pattern: `esxcli system syslog config logfilter {cmd} [cmd options]`.

For example, to get the list of available log filters, run the following command: `[root@xxx-xx-dhcp-xx-xx:~] esxcli system syslog config logfilter list`.

Use the `set` command to activate or deactivate log filtering: `[root@xxx-xx-dhcp-xx-xx:~] esxcli system syslog config logfilter set`.

Use the `add` command to add a log filter and the `remove` command to remove a log filter.

Use the `get` command to determine if log filtering is enabled.

A log filter is specified by three components and uses the following syntax: `numLogs | ident | logRegexp`.

Parameter	Description
`numLogs`	Specifies the number of matches of the logRegexp Python regular expression that will be allowed before filtering begins.
`ident`	The `ident` string is how an application identifies itself to the syslog facility. The `logRegexp` filter must be associated with the same application. You can find the `ident` string of an application by inspecting the log files in `/var/run/log`. The third field of each log file begins with the `ident` string and ends with `[`.
`logRegexp`	Python regular expression that identifies the messages which you want to filter out.

For example, to filter out all messages from the hostd daemon that contain the word "mark" after the tenth occurrence, use the following command: `esxcli system syslog config logfilter add --filter="10|Hostd|mark"`.

To remove the log filter, use the command `esxcli system syslog config logfilter remove --filter="10|Hostd|mark"`.

Set the Host Image Profile Acceptance Level

The Host Image Profile acceptance level determines which vSphere installation bundles (VIBs) are accepted for installation.

Required privileges: **Host** > **Configuration** > **SecurityProfile** and **Host** > **Configuration** > **Firewall**

VIB signatures are checked and accepted for installation based on a combination of the VIB acceptance level and the host image profile acceptance level. VIBs are tagged with an acceptance level that depends on their signature status.

See Working with Acceptance Levels.

1. From the vSphere Client, connect to the vCenter Server.
2. Select the host in the inventory.
3. Click the **Configure** tab.
4. Under System, select **Security Profile**.
5. Scroll down to Host Image Profile Acceptance Level, and click **Edit**.
6. Select the acceptance level and click **OK**.

Table 30: Host Image Profile Acceptance Levels

Host Image Profile Acceptance Level	Accepted Levels of VIBs
VMware Certified	VMware Certified
VMware Accepted	VMware Certified, VMware Accepted
Partner Supported	VMware Certified, VMware Accepted, Partner Supported
Community Supported	VMware Certified, VMware Accepted, Partner Supported, Community Supported

Remove All Custom Packages on ESX

After adding custom packages, you might decide to remove them.

Before you remove custom packages, shut down or migrate running virtual machines off of the ESX host.

1. Reboot the ESX host.
2. In the direct console, select **Remove Custom Extensions** and press F11 to confirm.
3. Reboot the host.

All custom packages are removed.

Modify ESX Configuration Files

You can modify ESX configuration files in the ESX Configuration Store (ConfigStore) by using the `/bin/configstorecli` tool.

The goal of the ESX Shell tool `configstorecli`, introduced in ESX 7.0 Update 1, is to manage all configurations for an ESX host centrally, instead of using different methods and a variety of configuration files.

For more information on how to manage ConfigStore, see Broadcom knowledge base article 312190.

Deactivate Support for Non-ASCII Characters on ESX

You can deactivate support for non-ASCII characters for virtual machine files and directory names by using two methods, depending on the ESX version.

By default, ESX supports the use of non-ASCII characters for virtual machine file and directory names.

If you need to deactivate support for non-ASCII characters, for ESX 7.0 Update 2 and later, see Broadcom knowledge base articles 393232 and 312190.

Prior to ESX 7.0 Update 2, you can deactivate this support by modifying the `/etc/vmware/hostd/config.xml` file with the following steps:

1. Using a text editor, open the `/etc/vmware/hostd/config.xml` file for the ESX host.
2. Within the `<config></config>` tag, add the following code.

   ```
   <g11nSupport>false</g11nSupport>
   ```
3. Save and close the file.
4. Reboot the host.

   After you deactivate this support, you can still enter non-ASCII characters for virtual machine names. vSphere user interfaces display the virtual machine names in the non-ASCII characters, but ESX converts the actual file and directory names to ASCII strings.

Reset the System Configuration

If you are having trouble determining the source of a problem with your ESX host, you can reset the system configuration.

Before resetting the configuration, back up your ESX configuration in case you want to restore your configuration.

Changes in the system configuration can be related to various problems, including problems with connectivity to the network and devices. Resetting the system configuration might solve such problems. If resetting the system configuration does not solve the problem, it can still rule out configuration changes made since the initial setup as the source of the problem.

When you reset the configuration, the software overrides all your configuration changes, deletes the password for the administrator account (root), and reboots the host. Configuration changes made by your hardware vendor, such as IP address settings and license configuration, might also be deleted.

Resetting the configuration does not remove virtual machines on the ESX host. After you reset the configuration defaults, the virtual machines are not visible, but you make them visible again by reconfiguring storage and reregistering the virtual machines.

> **CAUTION:**
> When you reset the configuration defaults, users accessing the host lose connectivity.

1. Back up the configuration by using the `Get-VMHostFirmware` VCF PowerCLI cmdlet.
2. From the direct console, select **Reset System Configuration** and press **Enter**.
3. Press **F11** to confirm.

The system reboots after all settings are reset to the default values.

After You Install and Set Up ESX

After you install and set up ESX, you can use manage hosts by various interfaces, license the hosts, and back up your configuration.

After ESX is installed and set up, you can manage the host by using the vSphere Client and vCenter, license the host, and back up your ESX configuration. You can also use the VMware Host Client to connect directly to the ESX host and to manage it. For information about installing and using the VMware Host Client, see *vSphere Single Host Management*.

> **Note:**
>
> When you install a standalone ESX host with TMP enabled that is not connected to a vCenter instance, create a backup of the ESX configuration recovery key. To get the recovery key, run the command `esxcli system settings encryption recovery list` on the ESX host and note it down. It is possible that the host might not be able to complete booting due to host configuration encryption related problems and in such cases, you can restore the host configuration by using the recovery key and running the configuration recovery process.
>
> For best practices and VMware recommendations, see the *vSphere Security* guide.

View System Logs

System logs provide detailed information about system operational events.

1. From the direct console, select **View System Logs**.
2. Press a corresponding number key to view a log.
   vCenter Agent (vpxa) logs appear if you add the host to vCenter.
3. Press Enter or the spacebar to scroll through the messages.
4. Perform a regular expression search.
   a) Press the slash key (/).
   b) Type the text to find.
   c) Press Enter.
   The found text is highlighted on the screen.
5. Press q to return to the direct console.

See also Configure Syslog on ESX Hosts.

Troubleshooting ESX Booting

The ESX booting troubleshooting topics provide solutions to problems that you might encounter during the ESX booting.

- Host Stops Unexpectedly at Bootup When Sharing a Boot Disk with Another Host
- Host Fails to Boot After You Install ESX in UEFI Mode

Host Stops Unexpectedly at Bootup When Sharing a Boot Disk with Another Host

When more than one host, either physical or virtual, boots from the same shared physical disk or LUN, they cannot use the same scratch partition.

The host stops at bootup when sharing a boot disk with another host.

More than one ESX host can share the same physical disk or LUN. When two such hosts also have the same scratch partition configured, either of the hosts can fail at bootup.

1. Set the hosts to boot sequentially, and boot the hosts.
   This setting lets you start the hosts so that you can change the scratch partition for one of them.
2. From the vSphere Client, connect to the vCenter.
3. Select the host in the inventory.
4. Click the **Configure** tab.
5. Under System, select **Advanced System Settings**.
6. Select **ScratchConfig**.
   The **ScratchConfig.CurrentScratchLocation** text box shows the current location of the scratch partition.
7. In the **ScratchConfig.ConfiguredScratchLocation** text box, enter a directory path that is unique for this host. For example, `/vmfs/volumes/`*`DatastoreUUID`*`/`*`DatastoreFolder`*.
8. Reboot the host for the changes to take effect.

Host Fails to Boot After You Install ESX in UEFI Mode

After you install ESX on a host machine in UEFI mode, the machine might fail to boot.

When you install or upgrade ESX, the installer tries to create aUEFI boot option named VMwareESX and make it the default boot option. When you reboot after installing ESX the reboot might fail. This problem is accompanied by an error message similar to `No boot device available.`

- When the installer creates the UEFI boot option, a problem occurs while writing to the NVRAM on the host motherboard.
- The host firmware does not recognize the attempt to set the UEFI boot option as the first boot option, or the firmware overrides the boot order.
- Either or both BIOS and firmware are outdated.
- The boot disk has an MBR or MSDOS partition table. Due to a technical limitation, the UEFI boot option is only created for a GUID Partition Table (GPT) partition table.

  Note:

  UEFI firmware attempts to load the boot image from the EFI system partition, which is FAT based, on the disk. Booting from the EFI system partition only works if the disk is laid out by using a GPT. If the boot disk has an MBR or MSDOS partition table, a UEFI boot fails. You cannot add a boot entry for MBR. If the disk is fully consumed by ESX, it cannot be converted to GPT, and you must boot in legacy BIOS mode.

1. While the error message is displayed on screen, open the boot options menu. Depending on your system, the boot options menu might open with a keyboard shortcut, in the BIOS menu, or in a BMC, iLO or iDRAC interface.
2. Check if a boot option VMwareESX exists and try to boot from it. If the boot is successful, change the boot order and set VMwareESX as the first boot option.
3. If the problem is not resolved, select an option similar to **Add boot option**.
   The wording and location of the option might vary, depending on your system.
4. Select the file `\EFI\BOOT\BOOTx64.EFI` on the disk that you installed ESX on.
5. Change the boot order so that the host boots from the option that you added.

Decommission an ESX Host

If you do not want your server to be an ESX host, you can decommission the ESX host machine.

1. Remove VMFS datastores on the internal disks so that the internal disks are no longer set up to store virtual machines.
2. Change the boot setting in the BIOS so that the host no longer boots into ESX.

   If you installed ESX in UEFI mode, delete the boot option VMwareESX or any other boot option created manually.
3. Install another operating system in its place.

ESX Upgrade

VMware ESX Upgrade describes how to upgrade VMware ESX™ to the current version.

Intended Audience

VMware ESX Upgrade is for anyone who needs to upgrade from earlier versions of ESX. These topics are for experienced Microsoft Windows or Linux system administrators who are familiar with virtual machine technology and data center operations.

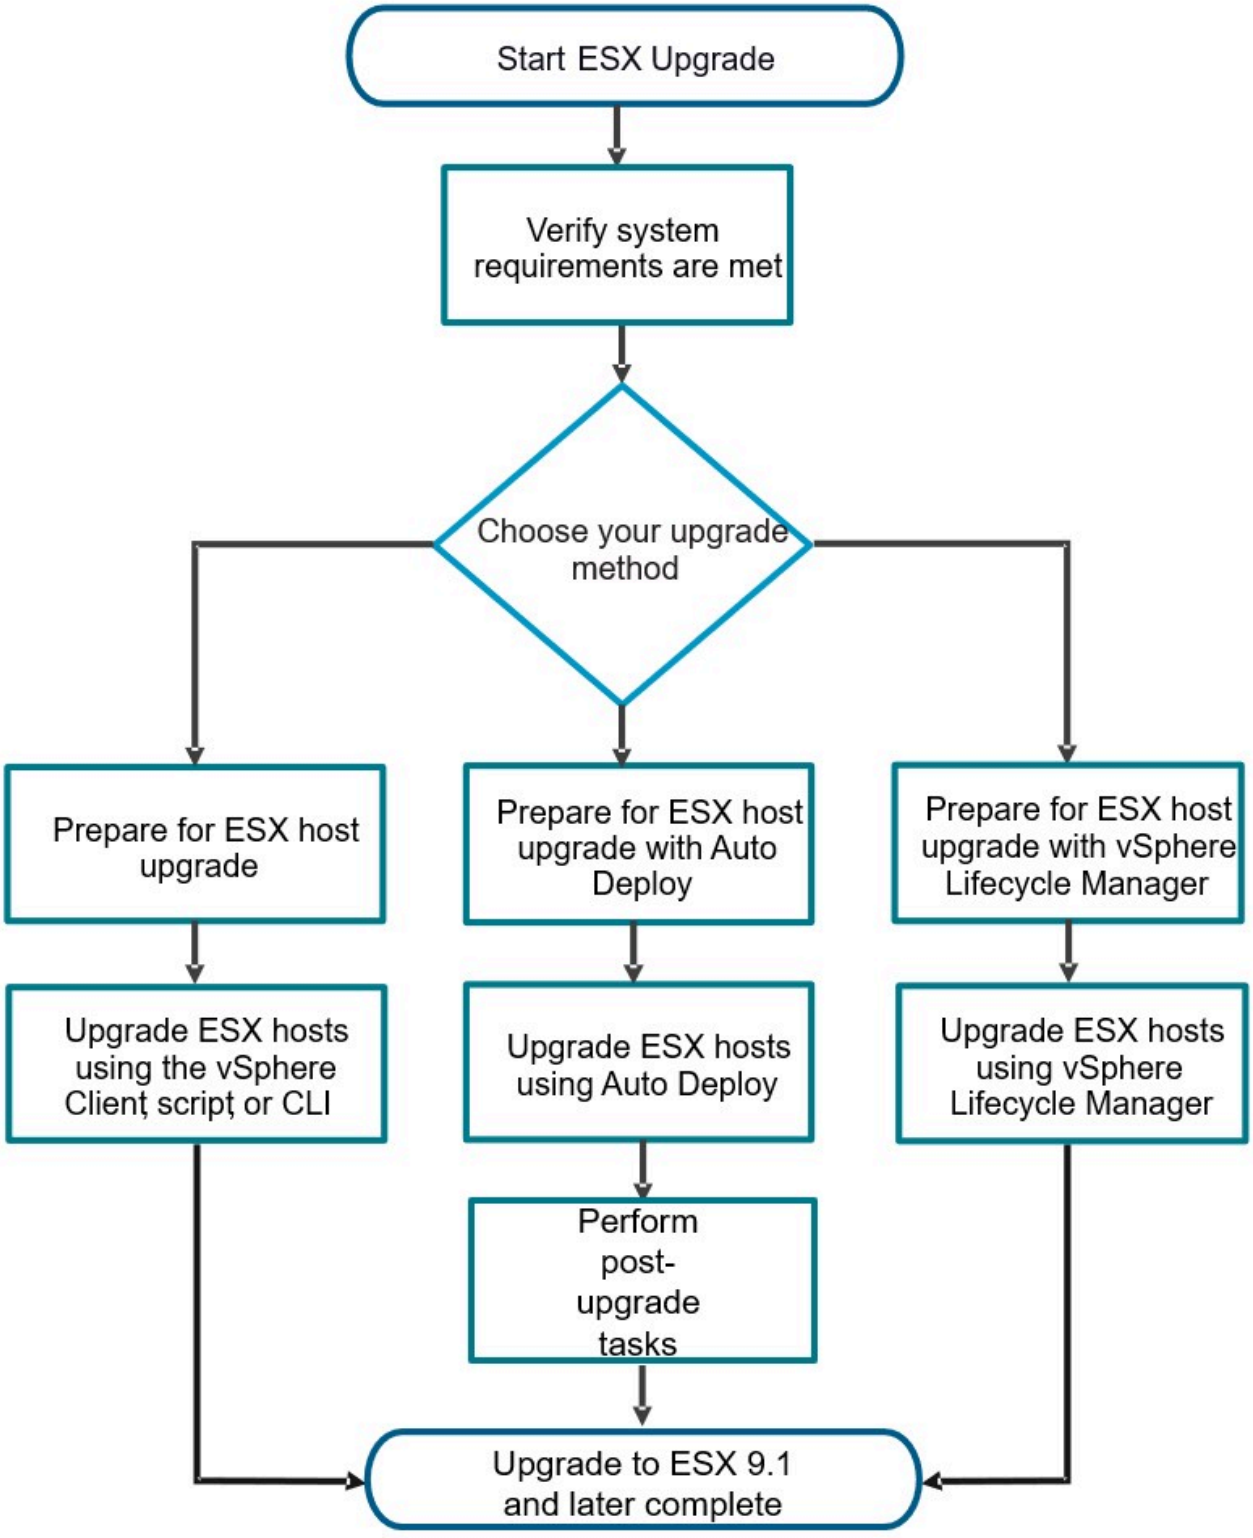
Overview of the ESX Host Upgrade Process

The details and level of support for an upgrade to ESX 9.1 depend on the ESX host to be upgraded and the upgrade method that you use.

Before you start an upgrade, verify that the upgrade path from your current version of ESX to the version to which you are upgrading, is supported. For more information, see the Broadcom Compatibility Guide.

You can upgrade an ESX host to version 9.1 by using an interactive upgrade from a CD, DVD, or USB, a scripted upgrade, ESXCLI, or vSphere Lifecycle Manager. When you upgrade an ESX host that has custom VIBs to version 9.1, all supported custom VIBs are migrated. For more information, see Upgrading Hosts That Have Third-Party Custom VIBs.

Figure 12: Overview of the ESX Host Upgrade Process



The following high-level steps are for upgrading ESX.

1. Verify that your system meets the upgrade requirements. See ESX Requirements.
2. Prepare your environment before upgrading. See Before Upgrading ESX Hosts.

3. Determine where you want to locate and boot the ESX installer. See Media Options for Booting the ESX Installer. If you are network booting the installer, verify that your network boot infrastructure is properly set up. See Network Booting the ESX Installer.
4. Upgrade ESX.
5. After upgrading ESX hosts, they automatically connect back to the vCenter and you must apply licenses. See After You Upgrade ESX Hosts.

CAUTION:

If you upgrade ESX hosts managed by vCenter, you must upgrade vCenter before you upgrade the ESX hosts. If you do not upgrade your environment in the correct order, you might lose data and lose access to servers.

The following methods are supported for a direct upgrade to ESX 9.1.

- Use the interactive graphical user interface (GUI) installer from a CD, DVD, or USB drive.
- Perform a scripted upgrade.
- Use ESXCLI.
- Use vSphere Auto Deploy. If the ESX host is deployed by using vSphere Auto Deploy, you can use vSphere Auto Deploy to reprovision the ESX host with a 9.1 image.
- Use the vSphere Lifecycle Manager.

Graphical User Interface (GUI) Installer	You can upgrade interactively by using an ESX installer ISO image on a CD, DVD, or USB flash drive or by network booting the installer. This method is appropriate for deployments with a few hosts. If during the installation process, you select a target disk that contains an ESX installation, the installer upgrades the host to ESX version 9.1. The installer also gives you the option to migrate some existing ESX host settings and configuration files and to preserve the existing VMFS datastore. See Upgrade Hosts Interactively.
Perform a Scripted Upgrade	To do a scripted upgrade, you can use the ESX 9.1 installer from a CD, DVD, or USB flash drive or by network booting the installer. This method is an efficient way to deploy multiple hosts. For more information, see Installing or Upgrading Hosts by Using a Script.
ESXCLI	You can use ESXCLI to upgrade hosts to ESX 9.1. ESX 9.1 introduces configuration files, components, base images, and add-ons as new software deliverables that you can use to update or patch ESX 9.1 hosts. For information about managing components, base images, and add-ons on ESX, see *ESXCLI Concepts and Examples*. To use ESXCLI commands, you must install Standalone ESXCLI. For more information about installing and using ESXCLI, see the following documents. • Getting Started with ESXCLI • ESXCLI Concepts and Examples See Upgrading Hosts by Using ESXCLI Commands .
vSphere Auto Deploy	If an ESX host is deployed with vSphere Auto Deploy, you can use vSphere Auto Deploy to reprovision the host and reboot it with a new image profile or a configuration that you manage on a cluster level. An image profile contains an ESX upgrade or patch, a host configuration profile, and optionally, third-party drivers or management agents that are provided by VMware partners. To add ESX hosts to a cluster that manages ESX configuration at a cluster level, you create a rule in Auto Deploy that assigns such a cluster as the host location for newly added hosts, which inherit the same settings and do not require manual configuration.You can build custom images by using vSphere ESX Image Builder CLI. For more information, see Using vSphere Auto Deploy to Reprovision Hosts .
vSphere Lifecycle Manager	vSphere Lifecycle Manager is a vCenter service for installing, upgrading, and updating ESX hosts. By using images and baselines, vSphere Lifecycle Manager enables centralized and simplified lifecycle management for multiple ESX hosts at a cluster level. For more information about performing orchestrated installations, upgrades, and updates, see the *Managing Host and Cluster Lifecycle* documentation.

For more information, see Upgrading to VMware Cloud Foundation 9.1.x and Upgrading to vSphere Foundation 9.1.x.

Upgrading Virtual Machines and VMware Tools

After you upgrade an ESX host, you can upgrade the virtual machines on the host to take advantage of new features.

You have the following tools for upgrading virtual machines.

vSphere Client	You can use the vSphere Client to upgrade a virtual machine step by step. For more information about upgrading virtual machines, see the *vSphere Virtual Machine Administration* documentation.

vSphere Lifecycle Manager	You can use the vSphere Lifecycle Manager to upgrade the virtual machine hardware and VMware Tools versions of the virtual machines in your environment. The vSphere Lifecycle Manager automates the upgrade process and verifies that the steps occur in the correct order. For more information, see the *Managing Host and Cluster Lifecycle* documentation.

Before Upgrading ESX Hosts

For a successful upgrade of your ESX hosts, understand and prepare for the changes that are involved.

For a successful ESX upgrade, follow these best practices:

1. Make sure that you understand the ESX upgrade process, the effect of that process on your existing deployment, and the preparation required for the upgrade.
   - If your vSphere system includes VMware solutions or plug-ins, make sure they are compatible with the vCenter Server version that you are upgrading to. See the Broadcom Product Interoperability Matrix.
   - Read Overview of the ESX Host Upgrade Process to understand the upgrade scenarios that are supported, and the options and tools that are available to perform the upgrade.
   - Read the vCenter and ESX Release Notes for known installation issues.
2. Prepare the system for the upgrade.
   - Make sure that the current ESX version is supported for the upgrade. See Overview of the ESX Host Upgrade Process.
   - Make sure that the system hardware complies with ESX requirements. See ESX Requirements and Broadcom Compatibility Guide. Check for system compatibility, I/O compatibility with network and host bus adapter (HBA) cards, storage compatibility, and backup software compatibility.
   - Make sure that sufficient disk space is available on the host for the upgrade.
   - If a SAN is connected to the host, detach the Fibre Channel system before continuing with the upgrade. Do not deactivate HBA cards in the BIOS.
3. Back up the host before performing an upgrade. If the upgrade fails, you can restore the host.
4. If you are using Auto Deploy to provision hosts, the user who is running the process must have local administrator privileges on the ESX host that is being provisioned. By default the installation process has these privileges and certificate provisioning happens as expected. However, if you are using another method than the installer, you must run it as a user who has the local administrator privileges.
5. Depending on the upgrade option you choose, you might need to migrate or power off all virtual machines on the host. See the instructions for your upgrade method.
   - For an interactive upgrade from CD, DVD, or USB drive: see Upgrade Hosts Interactively.
   - For a scripted upgrade: see Installation and Upgrade Scripts Used for ESX Installation.
   - For vSphere Auto Deploy: see Using vSphere Auto Deploy to Reprovision Hosts . If the ESX 8.0x or 9.0.x host was deployed by using vSphere Auto Deploy, you can use vSphere Auto Deploy to reprovision the host with a 9.1 image.
   - For the `esxcli` command method: see Upgrading Hosts by Using ESXCLI Commands .
6. Plan for the tasks that must be performed after the ESX host upgrade:
   - Test the system to ensure that the upgrade completed successfully.
   - Starting with ESX 9.0, you no longer license ESX hosts by using the vSphere Client. After you license the vCenter instance connected to the ESX hosts, they are licensed automatically. For more information, see Licensing Overview in the *Licensing* guide.
   - Consider setting up a syslog server for remote logging, to ensure sufficient disk storage for log files. Setting up logging on a remote host is especially important for hosts with limited local storage. You can optionally install Log Management, which provides log aggregation and analytics. See Required Free Space for System Logging.
7. If the upgrade was unsuccessful and you backed up the host, you can restore the host.

Upgrading Hosts That Have Third-Party Custom VIBs

A host can have custom vSphere Installation Bundles (VIBs) installed, for example, third-party drivers or management agents.

When you upgrade an ESX host to 9.1, all supported custom VIBs are migrated, regardless of whether the VIBs are included in the installer ISO. If the host or the installer ISO image contains a VIB that creates a conflict and prevents the

upgrade, an error message identifies the VIB that created the conflict. To upgrade the host, take one of the following actions:

- Remove the VIB that created the conflict from the ESX host and retry the upgrade. You can remove a VIB from the host by using `esxcli` commands. For more information, see Remove VIBs from a Host .
- Use the vSphere ESX Image Builder CLI to create a custom installer ISO image that resolves the conflict. See Customizing Installations with vSphere ESX Image Builder.

Upgrading ESX Hosts in an Environment With VMware NSX

In an NSX setup, before an upgrade to ESX 9.0 and later, make sure that the NSX kernel module is part of the image or upgrade baseline.

If your vSphere system includes NSX, before you start an upgrade of your ESX hosts, you must ensure that the NSX kernel module is part of the desired software specification or baseline that you use for the upgrade. When you upgrade an ESX host to 9.0 or later, all supported custom VIBs are migrated, regardless of whether the VIBs are included in the installer ISO. However, the NSX kernel module is not automatically migrated to the installer ISO image. Before you proceed to the upgrade operation, see Broadcom knowledge base article 312013.

Upgrade Hosts Interactively

To upgrade ESX hosts to ESX 9.1, you can boot the ESX installer from a CD, DVD, or USB flash drive.

- Verify that the ESX installer ISO in one of the following locations.
  - On CD or DVD. If you do not have the installation CD or DVD, you can create one. See Download and Burn the ESX Installer ISO Image to a CD or DVD.
  - On a USB flash drive. See Format a USB Flash Drive to Boot the ESX Installation or Upgrade.

    Note:

    You can also use PXE to boot the ESX installer to run an interactive installation or a scripted installation. See Overview of the Network Boot Installation Process.
- Verify that the server hardware clock is set to UTC. This setting is in the system BIOS or UEFI.
- If you are upgrading an ESX host, supported custom VIBs that are not included in the ESX installer ISO are migrated. See Upgrading Hosts That Have Third-Party Custom VIBs
- See your hardware vendor documentation for information about changing the boot order.

Before upgrading, consider disconnecting the network storage. This action decreases the time it takes the installer to search for available disk drives. When you disconnect network storage, any files on the disconnected disks are unavailable at installation. Do not disconnect a LUN that contains an existing ESX installation.

Note:

Upgrading an ESX host with a data processing unit (DPU) is not supported through the interactive or scripted installer. To upgrade such hosts, use vSphere Lifecycle Manager or ESXCLI.

1. Insert the ESX installer CD or DVD in the CD-ROM or DVD-ROM drive, or attach the Installer USB flash drive and restart the machine.
2. Set the BIOS or UEFI to boot from the CD-ROM device or the USB flash drive.
3. In the **Select a Disk** panel, select the drive on which to install or upgrade ESX and press Enter.

   Press F1 for information about the selected disk.

   Note:
   Do not rely on the disk order in the list to select a disk. The disk order is determined by the BIOS or UEFI. On systems where drives are continuously being added and removed, they might be out of order.
4. Upgrade or install ESX if the installer finds an existing ESX installation and VMFS datastore.

   If an existing VMFS datastore cannot be preserved, you can choose only to install ESX and overwrite the existing VMFS datastore, or to cancel the installation. If you choose to overwrite the existing VMFS datastore, back up the datastore first.

5. Press F11 to confirm and start the upgrade.
6. Remove the installation CD or DVD or USB flash drive when the upgrade is complete.
7. Press **Enter** to reboot the host.
8. Set the first boot device to be the drive which you selected previously when you upgraded ESX.

Installing or Upgrading Hosts by Using a Script

You can quickly deploy ESX hosts by using scripted, unattended installations or upgrades.

Scripted installations or upgrades provide an efficient way to deploy multiple hosts. The installation or upgrade script contains the installation settings for ESX. You can apply the script to all hosts that you want to have a similar configuration.

For a scripted installation or upgrade, you must use the supported commands to create a script. You can edit the script to change settings that are unique for each host.

> **Note:**
>
> Upgrading an ESX host with a data processing unit (DPU) is not supported through the interactive or scripted installer. To upgrade such hosts, use vSphere Lifecycle Manager or ESXCLI.

The installation or upgrade script can reside in one of the following locations:

- FTP server
- HTTP/HTTPS server
- NFS server
- USB flash drive
- CD-ROM drive

In the ESX Installation and Setup guide, see the following topics:

- Enter Boot Options to Run an Installation or Upgrade Script
- Boot Options
- About the boot.cfg File
- Locations Supported for Installation or Upgrade Scripts
- Path to the Installation or Upgrade Script
- Installation and Upgrade Script Commands
- Install or Upgrade ESX from a CD or DVD by Using a Script
- Install or Upgrade ESX from a USB Stick by Using a Script
- Network Boot the ESX Installer for a Scripted Installation or Upgrade

How to Upgrade Hosts by Using ESXCLI Commands

You can use ESXCLI commands to upgrade hosts.

In this chapter see:

- Upgrading Hosts by Using ESXCLI Commands
- See if ESX Host Update Requires Maintenance Mode or Reboot
- Place a Host in Maintenance Mode
- Update a Host with Individual VIBs
- Upgrade or Update a Host with Image Profiles
- Update ESX Hosts by Using Zip Files
- Remove VIBs from a Host
- Add Third-Party Extensions to Hosts with an ESXCLI Command
- Perform a Dry Run of an ESXCLI Installation or Upgrade
- List the Available VIBs and Profiles After Host Reboot
- Display the Image Profile and Acceptance Level of the Host

Upgrading Hosts by Using ESXCLI Commands

By using ESXCLI, you can upgrade to version 9.1 and update or patch ESX 9.1 hosts.

ESX 9.1 introduces configuration files, components, base images, and add-ons as new software deliverables that you can use to update or patch ESX9.1 hosts. For information about managing components, base images, and add-ons on ESX, see ESXCLI Concepts and Examples.

To use ESXCLI commands, you must install Standalone ESXCLI. For more information about installing and using ESXCLI, see the content under the Getting Started with ESXCLI chapter in VMware vSphere SDKs and Tools 9.1.

Note:

If you press Ctrl+C while an `esxcli` command is running, the command-line interface exits to a new prompt without displaying a message. However, the command continues to run to completion.

For ESX hosts deployed with vSphere Auto Deploy, the tools VIB must be part of the base booting image used for the initial Auto Deploy installation. The tools VIB cannot be added separately later.

VIBs, Image Profiles, and Software Depots

Upgrading ESX with esxcli commands requires an understanding of VIBs, image profiles, and software depots.

The following technical terms are used throughout the vSphere documentation set in discussions of installation and upgrade tasks.

VIB	A VIB is an ESXi software package. VMware and its partners package solutions, drivers, CIM providers, and applications that extend the ESXi platform as VIBs. VIBs are available in software depots. You can use VIBs to create and customize ISO images or to upgrade ESXi hosts by installing VIBs asynchronously onto the hosts.
Image Profile	An image profile defines an ESXi image and consists of VIBs. An image profile always includes a base VIB, and might include more VIBs. You examine and define an image profile by using vSphere ESXi Image Builder.
Software Depot	A software depot is a collection of VIBs and image profiles. The software depot is a hierarchy of files and folders and can be available through an HTTP URL (online depot) or a ZIP file (offline depot). VMware and VMware partners make depots available. Companies with large VMware installations might create internal depots to provision ESXi hosts with vSphere Auto Deploy, or to export an ISO for ESXi installation.

Understanding Acceptance Levels for VIBs and Hosts

Each VIB is released with an acceptance level that cannot be changed. The host acceptance level determines which VIBs can be installed to a host.

The acceptance level applies to individual VIBs installed by using the `esxcli software vib install` and `esxcli software vib update` commands, to VIBs installed using vSphere Lifecycle Manager, and to VIBs in image profiles.

The acceptance level of all VIBs on a host must be at least as high as the host acceptance level. For example, if the host acceptance level is VMwareAccepted, you can install VIBs with acceptance levels of VMwareCertified and VMwareAccepted, but you cannot install VIBs with acceptance levels of PartnerSupported or CommunitySupported. To install a VIB with a restrictive acceptance level that is less than the acceptance level of the host, you can change the setting of the host by using the vSphere Client or by running `esxcli software acceptance` commands.

Setting host acceptance levels is a best practice that allows you to specify which VIBs can be installed on a host and used with an image profile, and the level of support you can expect for a VIB. For example, you might set a more restrictive acceptance level for hosts in a production environment than for hosts in a testing environment.

VMware supports the following acceptance levels.

VMwareCertified	The VMwareCertified acceptance level has the most stringent requirements. VIBs with this level go through thorough testing fully equivalent to VMware in-house Quality Assurance testing for the same technology. Today, only I/O Vendor Program (IOVP) program drivers are published at this level. VMware takes support calls for VIBs with this acceptance level.

VMwareAccepted	VIBs with this acceptance level go through verification testing, but the tests do not fully test every function of the software. The partner runs the tests and VMware verifies the result. Today, CIM providers and PSA plug-ins are among the VIBs published at this level. VMware directs customers with support calls for VIBs with this acceptance level to contact the partner's support organization.
PartnerSupported	VIBs with the PartnerSupported acceptance level are published by a partner that VMware trusts. The partner performs all testing. VMware does not verify the results. This level is used for a new or nonmainstream technology that partners want to enable for VMware systems. Today, driver VIB technologies such as Infiniband, ATAoE, and SSD are at this level with nonstandard hardware drivers. VMware directs customers with support calls for VIBs with this acceptance level to contact the partner's support organization.
CommunitySupported	The CommunitySupported acceptance level is for VIBs created by individuals or companies outside of VMware partner programs. VIBs at this level have not gone through any VMware-approved testing program and are not supported by VMware Technical Support or by a VMware partner.

Table 31: VIB Acceptance Levels Required to Install on Hosts

Host Acceptance Level	VMwareCertified VIB	VMwareAccepted VIB	PartnerSupported VIB	CommunitySupported VIB
VMwareCertified	x			
VMwareAccepted	x	x		
PartnerSupported	x	x	x	
CommunitySupported	x	x	x	x

Match a Host Acceptance Level with an Update Acceptance Level

You can change the host acceptance level to match the acceptance level for a VIB or image profile that you want to install. The acceptance level of all VIBs on a host must be at least as high as the host acceptance level.

Install ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run esxcli commands in the ESX Shell.

Use this procedure to determine the acceptance levels of the host and the VIB or image profile to install, and to change the acceptance level of the host, if necessary for the update.

When you specify a target server by using `--server=<server_name>`, the server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see Getting Started with ESXCLI, or run `esxcli --help` at the ESXCLI command prompt.

1. Retrieve the acceptance level for the VIB or image profile.

Option	Description
List information for all VIBs	`esxcli --server=<server_name> software sources vib list --depot=<depot_URL>`
List information for a specified VIB	`esxcli --server=<server_name> software sources vib list --viburl=<vib_URL>`
List information for all image profiles	`esxcli --server=<server_name> software sources profile list --depot=<depot_URL>`
List information for a specified image profile	`esxcli --server=<server_name> software sources profile get --depot=<depot_URL> --profile=<profile_name>`

2. Retrieve the host acceptance level.

   ```
   esxcli --server=<server_name> software acceptance get
   ```

3. Optional: If the acceptance level of the VIB is more restrictive than the acceptance level of the host, change the acceptance level of the host.

   ```
   esxcli --server=<server_name> software acceptance set --level=<acceptance_level>
   ```

   The *acceptance_level* can be `VMwareCertified`, `VMwareAccepted`, `PartnerSupported`, or `CommunitySupported`. The values for *acceptance_level* are case-sensitive.

Note:
You can use the --force option for the `esxcli software vib` or `esxcli software profile` command to add a VIB or image profile with a lower acceptance level than the host. A warning appears. Because your setup is no longer consistent, the warning is repeated when you install VIBs, remove VIBs, and perform certain other operations on the host.

See if ESX Host Update Requires Maintenance Mode or Reboot

VIBs that you can install with a live installation do not require the host to be rebooted, but might require the host to be placed in maintenance mode.

Other VIBs and profiles might require the host to be rebooted after the installation or update.

Install vCLI or deploy the vSphere Management Assistant (vMA) virtual machine. See the chapter Getting Started with ESXCLI. For troubleshooting, run ESXCLI commands in the ESX Shell.

When you specify a target server by using `--server=<server_name>` in the procedure, the specified server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see ESXCLI Syntax, or run `esxcli --help` at the vCLI command prompt.

1. Check whether the VIB or image profile that you want to install requires the host to be placed in maintenance mode or to be rebooted after the installation or update.

   Run one of the following commands.

Option	Description
Check the VIB	`esxcli --server=<server_name> software sources vib get -v <vib_URL>`
Check the VIBs in a depot	`esxcli --server=<server_name> software sources vib get --depot=<depot_name>`
Check the image profile in a depot	`esxcli --server=<server_name> software sources profile get --depot=<depot_name>`

2. Review the return values.

   The return values, which are read from the VIB metadata, indicate whether the host must be in maintenance mode before installing the VIB or image profile, and whether installing the VIB or profile requires the host to be rebooted.

   Note:
   vSphere Lifecycle Manager relies on an internal ESX software scan API to determine whether maintenance mode is required or not. When you install a VIB on a live system, if the value for `Live-Install-Allowed` is set to false, the installation result instructs vSphere Lifecycle Manager to reboot the host. When you remove a VIB from a live system, if the value for `Live-Remove-Allowed` is set to false, the removal result instructs vSphere Lifecycle Manager to reboot the host. In either case, when the remediation starts, vSphere Lifecycle Manager automatically puts the host into maintenance mode.

If necessary, place the host in maintenance mode. See Place a Host in Maintenance Mode. If a reboot is required, and if the host belongs to a VMware HA cluster, remove the host from the cluster or disable HA on the cluster before the installation or update. Also, place the host in maintenance mode to minimize boot disk activity during the upgrade.

Place a Host in Maintenance Mode

Some installation and update operations that use live install require the host to be in maintenance mode.

Install Standalone ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.

Maintenance mode is required when an update operation requires a reboot. However, you only put the host in maintenance mode manually when you use esxcli commands for update and upgrade operations.

To determine whether an upgrade operation requires the host to be in maintenance mode, see See if ESX Host Update Requires Maintenance Mode or Reboot

Note:

If the host is a member of a vSAN cluster, and any virtual machine object on the host uses the "Number of failures to tolerate=0" setting in its storage policy, the host might experience unusual delays when entering maintenance mode. The delay occurs because vSAN has to evacuate this object from the host for the maintenance operation to complete successfully.

When you specify a target server by using `--server=<server_name>` in the procedure, the specified server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see ESXCLI Syntax, or run `esxcli --help` at the vCLI command prompt.

1. Check whether the host is in maintenance mode.

   ```
   esxcli --server=<server_name> system maintenanceMode get
   ```

2. Power off each virtual machine running on the ESX host.

   Note:
   You can list all running virtual machines and retrieve the World ID of each one by running the following command.

   ```
   esxcli --server=<server_name> vm process list
   ```

Option	Command
To shut down the guest operating system and then power off the virtual machine	`esxcli --server=<server_name> vm process kill --type soft --world-id <vm_ID>`
To power off the virtual machine immediately	`esxcli --server=<server_name> vm process kill --type hard --world-id <vm_ID>`
To force the power off operation	`esxcli --server=<server_name> vm process kill --type force --world-id <vm_ID>`

   Alternatively, to avoid powering off virtual machines, you can migrate them to another host. See the topic about migrating virtual machines in the *vCenter and Host Management* documentation.

3. Place the host in maintenance mode.

   ```
   esxcli --server=<server_name> system maintenanceMode set --enable true
   ```

4. Verify that the host is in maintenance mode.

   ```
   esxcli --server=<server_name> system maintenanceMode get
   ```

Update a Host with Individual VIBs

You can update a host with VIBs stored in a software depot that is accessible through a URL or in an offline ZIP depot.

- Install Standalone ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.
- Determine whether the update requires the host to be in maintenance mode or to be rebooted. If necessary, place the host in maintenance mode.
  See See if ESX Host Update Requires Maintenance Mode or Reboot. See Place a Host in Maintenance Mode.
- If the update requires a reboot, and if the host belongs to a vSphere HA cluster, remove the host from the cluster or deactivate HA on the cluster.

Important:

If you are updating ESX from a zip bundle in a VMware-supplied depot, either online from the Broadcom Support Portal or downloaded locally, VMware supports only the update method specified for VMware-supplied depots in the topic Upgrade or Update a Host with Image Profiles .

Note:

The `esxcli software vib update` and `esxcli software vib install` commands are not supported for upgrade operations. See Upgrade or Update a Host with Image Profiles .

When you specify a target server by using `--server=<server_name>` in the procedure, the specified server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see ESXCLI Syntax, or run `esxcli --help` at the vCLI command prompt.

1. Determine which VIBs are installed on the host.

   ```
   esxcli --server=<server_name> software vib list
   ```

2. Find out which VIBs are available in the depot.

Option	Description
From a depot accessible by URL	`esxcli --server=<server_name> software sources vib list --depot=http://<web_server>/<depot_name>`
From a local depot ZIP file	`esxcli --server=<server_name> software sources vib list --depot=<absolute_path_to_depot_zip_file>`

   You can specify a proxy server by using the --proxy option.

3. Update the existing VIBs to include the VIBs in the depot or install new VIBs.

Option	Description
Update VIBs from a depot accessible by URL	`esxcli --server=<server_name> software vib update --depot=http://<web_server>/<depot_name>`
Update VIBs from a local depot ZIP file	`esxcli --server=<server_name> software vib update --depot=<absolute_path_to_depot_ZIP_file>`
Install all VIBs from a ZIP file on a specified offline depot (includes both VMware VIBs and partner-supplied VIBs)	`esxcli --server=<server_name> software vib install --depot <path_to_VMware_vib_ZIP_file> \<VMware_vib_ZIP_file> --depot <path_to_partner_vib_ZIP_file> \<partner_vib_ZIP_file>`

   Options for the `update` and `install` commands allow you to perform a dry run, to specify a specific VIB, to bypass the acceptance level verification, and so on. Do not bypass verification on production systems. See the *ESXCLI Reference*.

4. Verify that the VIBs are installed on your ESX host.

   ```
   esxcli --server=<server_name> software vib list
   ```

Upgrade or Update a Host with Image Profiles

You can upgrade or update a host with image profiles stored in a software depot that is accessible through a URL or in an offline ZIP depot.

- Install Standalone ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.
- Determine whether the update requires the host to be in maintenance mode or to be rebooted. If necessary, place the host in maintenance mode.
  See See if ESX Host Update Requires Maintenance Mode or Reboot. See Place a Host in Maintenance Mode.

  Important:
  When you use ESXCLI to update or upgrade the host, put the host manually in maintenance mode to ensure that the boot disk is not actively in use before the upgrade begins.
- If the update requires a reboot, and if the host belongs to a vSphere HA cluster, remove the host from the cluster or deactivate HA on the cluster.

You can use the `esxcli software profile update` or `esxcli software profile install` command to upgrade or update an ESX host.

When you upgrade or update a host, the `esxcli software profile update` or `esxcli software profile install` command applies a later version (major or minor) of a full image profile onto the host. After this operation and a reboot, the host can join a vCenter environment of the same or later version.

The `esxcli software profile update` command brings the entire content of the ESX host image to the same level as the corresponding upgrade method using an ISO installer. However, the ISO installer performs a pre-upgrade check for potential problems, such as insufficient memory or unsupported devices.

For more about the ESX upgrade process and methods, see Overview of the ESX Host Upgrade Process.

Important:

If you are upgrading or updating ESX from a VMware online depot or an offline .zip bundle downloaded locally from the Broadcom Support Portal, VMware supports only the update command `esxcli software profile update --depot=<depot_location> --profile=<profile_name>`. ESXCLI commands support 2 types of depot location: either a full path to a locally downloaded offline .zip bundle, such as `/vmfs/volumes/<datastore_name>/<depot_ name>.zip`, or an `http/https` link to the `index.xml` in an online depot, such as `https//<web_server>/<depot_name>/index.xml`. You can extract an offline .zip bundle and host it as an online depot on a private `http/https` server accessible to an ESX host.

When you specify a target server by using `--server=<server_name>` in the procedure, the specified server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see ESXCLI Syntax, or run `esxcli --help` at the vCLI command prompt.

Note:

Options to the `update` and `install` commands allow you to perform a dry run, to bypass acceptance level verification, to ignore hardware compatibility check warnings, and so on. The option to bypass hardware compatibility check warnings is only available for ESX 6.7 Update 1 or later. Do not bypass verification on production systems.

For options help, type `esxcli software profile install --help` or `esxcli software profile update --help`. For the complete listing of available command-line options, see the ESXCLI Reference.

1. Determine which VIBs are installed on the host.

   ```
   esxcli --server=<server_name> software vib list
   ```

2. Determine which image profiles are available in the depot.

   ```
   esxcli --server=<server_name> software sources profile list --depot=http://<depot_location>/<depot_name>
   ```

   You can specify a proxy server by using the --proxy option.

3. Update the existing image profile to include the VIBs or install new VIBs.

Option	Description
Update the image profile from a VMware-supplied ZIP bundle, in a depot, accessible online from the Broadcom Support Portal or downloaded to a local depot	`esxcli software profile update --depot=<depot_location> --profile=<profile_name>` **Important:** This is the only update method that VMware supports for zip bundles supplied by VMware. VMware-supplied ZIP bundle names take the form: `VMware-ESX-<version_number>-<build_number>-depot.zip`. The profile name for VMware-supplied zip bundles takes one of the following forms. • `ESX-<version_number>-<build_number>-standard` • `ESX-<version_number>-<build_number>-notools` (does not include VMware Tools)
Update the image profile from a depot accessible by URL	`esxcli --server=<server_name> software profile update --depot=http://<depot_location>/<depot_name> --profile=<profile_name>`

Option	Description
Update the image profile from ZIP file stored locally on the target server	`esxcli --server=<server_name> software profile update --depot=file:///<path_to_profile_ZIP_file>/<profile_ZIP_file> --profile=<profile_name>`
Update the image profile from a ZIP file on the target server, copied into a datastore	`esxcli --server=<server_name> software profile update --depot=<datastore_name>/<profile_ZIP_file> --profile=<profile_name>`
Update the image profile from a ZIP file copied locally and applied on the target server	`esxcli --server=<server_name> software profile update --depot=/<root_dir>/<path_to_profile_ZIP_file>/<profile_ZIP_file> --profile=<profile_name>`
Install all new VIBs in a specified profile accessible by URL	`esxcli --server=<server_name> software profile install --depot=http://<depot_location>/<depot_name> --profile=<profile_name>`
Install all new VIBs in a specified profile from a ZIP file stored locally on the target.	`esxcli --server=<server_name> software profile install --depot=file:///<path_to_profile_ZIP_file>/<profile_ZIP_file> --profile=<profile_name>`
Install all new VIBs from a ZIP file on the target server, copied into a datastore	`esxcli --server=<server_name> software profile install --depot=<datastore_name>/<profile_ZIP_file> --profile=<profile_name>`
Install all new VIBs from a ZIP file copied locally and applied on the target server	`esxcli --server=<server_name> software profile install --depot=/<root_dir>/<path_to_profile_ZIP_file>/<profile_ZIP_file> --profile=<profile_name>`

Important:
The `software profile update` command updates existing VIBs with the corresponding VIBs from the specified profile, but does not affect other VIBs installed on the target server. The `software profile install` command installs the VIBs present in the depot image profile, and removes any other VIBs installed on the target server.

4. Reboot the ESX host immediately if in the ESXCLI output you see `Reboot Required: true`.

   Note:
   If you do not reboot the ESX host and continue, further modifications to the host, such as installation of a VIB, might fail or not take effect due to the pending reboot.

5. Verify that the VIBs are installed on your ESX host.

   ```
   esxcli --server=<server_name> software vib list
   ```

Update ESX Hosts by Using Zip Files

You can update hosts with VIBs or image profiles by downloading a ZIP file of a depot.

- Install Standalone ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.
- Download the ZIP file of a depot bundle from a third-party VMware partner.
- Determine whether the update requires the host to be in maintenance mode or to be rebooted. If necessary, place the host in maintenance mode.
  See See if ESX Host Update Requires Maintenance Mode or Reboot. See Place a Host in Maintenance Mode.
- If the update requires a reboot, and if the host belongs to a vSphere HA cluster, remove the host from the cluster or deactivate HA on the cluster.

VMware partners prepare third-party VIBs to provide management agents or asynchronously released drivers.

Important:
If you are upgrading or updating ESX from a zip bundle in a VMware-supplied depot, either online from the Broadcom Support Portal or downloaded locally, the `esxcli software vib update` and `esxcli software vib install` commands are not supported. VMware supports only the update and upgrade methods specified for VMware-supplied depots in the topic Upgrade or Update a Host with Image Profiles .If the depot is not supplied by VMware and does not have an image profile, you can use the `esxcli software vib update` and `esxcli software vib install` commands for individual or multiple VIB updates as described in Update a Host with Individual VIBs and the procedure in this topic.

When you specify a target server by using `--server=<server_name>` in the procedure, the specified server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see ESXCLI Syntax, or run `esxcli --help` at the vCLI command prompt.

Install the ZIP file.

```
esxcli --server=<server_name> software vib update --depot=/<path_to_vib_ZIP>/<ZIP_file_name>.zip
```

Remove VIBs from a Host

You can uninstall third-party VIBs or VMware VIBs from your ESX host, unless the VIB is part of a Component that is required for the ESX lifecycle or a driver.

- If the removal requires a reboot, and if the host belongs to a vSphere HA cluster, deactivate HA for the host.
- Determine whether the update requires the host to be in maintenance mode or to be rebooted. If necessary, place the host in maintenance mode.
  See See if ESX Host Update Requires Maintenance Mode or Reboot. See Place a Host in Maintenance Mode.
- Install Standalone ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.

  Note:

  To ensure that the boot disk is not actively in use when you use ESXCLI to update or upgrade the host, put the host manually in maintenance mode.

VMware partners prepare third-party VIBs to provide management agents or asynchronously released drivers.

Important:
Starting with ESX 8.0 Update 2, removing some VIBs from their Components can cause runtime issues with ESX.

Table 32: VIBs required for ESX image completeness.

Component	VIBs
ESX	bmcal
	bmcal-esxio
	clusterstore
	cpu-microcode
	crx

	vmkusb-esxio

1. Power off each virtual machine running on the ESX host.

   Note:
   You can list all running virtual machines and retrieve the World ID of each one by running the following command.
   ```
   esxcli --server=<server_name> vm process list
   ```

Option	Command
To shut down the guest operating system and then power off the virtual machine	`esxcli --server=<server_name> vm process kill --type soft --world-id <vm_ID>`
To power off the virtual machine immediately	`esxcli --server=<server_name> vm process kill --type hard --world-id <vm_ID>`
To force the power off operation	`esxcli --server=<server_name> vm process kill --type force --world-id <vm_ID>`

   Alternatively, to avoid powering off virtual machines, you can migrate them to another host. See the topic about migrating virtual machines in the *vCenter and Host Management* documentation.

2. Place the host in maintenance mode.
   ```
   esxcli --server=<server_name> system maintenanceMode set --enable true
   ```
3. If necessary, shut down or migrate virtual machines.
4. Determine which VIBs are installed on the host.
   ```
   esxcli --server=<server_name> software vib list
   ```
5. Remove the VIB.
   ```
   esxcli --server=<server_name> software vib remove --vibname=<name>
   ```
   Specify one or more VIBs to remove in one of the following forms.

- `<name>`
- `<name>:<version>`
- `<vendor>:<name>`
- `<vendor>:<name>:<version>`

For example, the command to remove a VIB specified by vendor, name and version can take the following form.

```
esxcli --server myEsxiHost software vib remove --
vibname=PatchVendor:patch42:version3
```

Note:
The `remove` command supports several more options. See the *ESXCLI Reference*.

Add Third-Party Extensions to Hosts with an ESXCLI Command

You can use the `esxcli software vib` command to add a third-party extension released as a VIB package to the system.

When you use this command, the VIB system updates the firewall rule set and refreshes the host daemon after you reboot the system.

Otherwise, you can use a firewall configuration file to specify port rules for host services to enable for the extension. The *vSphere Security* documentation discusses how to add, apply, and refresh a firewall rule set and lists the `esxcli network firewall` commands.

Perform a Dry Run of an ESXCLI Installation or Upgrade

You can use the --dry-run option to preview the results of an installation or upgrade operation.

A dry run of the installation or update procedure does not make any changes, but reports the VIB-level operations that will be performed if you run the command without the --dry-run option.

Install Standalone ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.

When you specify a target server by using `--server=<server_name>` in the procedure, the specified server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see ESXCLI Syntax, or run `esxcli --help` at the vCLI command prompt.

1. Enter the installation or upgrade command, adding the --dry-run option.
   - `esxcli --server=<server_name> software vib install --dry-run`
   - `esxcli --server=<server_name> software vib update --dry-run`
   - `esxcli --server=<server_name> software profile install --dry-run`
   - `esxcli --server=<server_name> software profile update --dry-run`
2. Review the output that is returned.
   The output shows which VIBs will be installed or removed and whether the installation or update requires a reboot.

List the Available VIBs and Profiles After Host Reboot

You can use the --rebooting-image option to list the VIBs and profiles that are installed on the host and will be active after the next host reboot.

Install Standalone ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.

When you specify a target server by using `--server=<server_name>` in the procedure, the specified server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see ESXCLI Syntax, or run `esxcli --help` at the vCLI command prompt.

1. Enter one of the following commands.

Option	Description
For VIBs	`esxcli --server=<server_name> software vib list --rebooting-image`
For Profiles	`esxcli --server=<server_name> software profile get --rebooting-image`

2. Review the output that is returned.

   The output displays information for the ESX image that will become active after the next reboot. If the pending-reboot image has not been created, the output returns nothing.

Display the Image Profile and Acceptance Level of the Host

You can use the `software profile get` command to display the currently installed image profile and acceptance level for the specified host.

Install Standalone ESXCLI. See Getting Started with ESXCLI. For troubleshooting, run `esxcli` commands in the ESX Shell.

This command also shows details of the installed image profile history, including profile modifications.

When you specify a target server by using `--server=<server_name>` in the procedure, the specified server prompts you for a user name and password. Other connection options, such as a configuration file or session file, are supported. For a list of connection options, see ESXCLI Syntax, or run `esxcli --help` at the vCLI command prompt.

1. Enter the following command.

   ```
   esxcli --server=<server_name> software profile get
   ```

2. Review the output.

Using vSphere Auto Deploy to Reprovision Hosts

You can reprovision ESXi hosts deployed by using vSphere Auto Deploy with a new image profile for a different version of ESXi.

> **Note:**
> If you upgrade the host to use an ESX 6.0 or later image, the vSphere Auto Deploy server provisions the ESX host with certificates that are signed by VMCA. If you are currently using custom certificates, you can set up the host to use the custom certificates after the upgrade. See *vSphere Security*.

If a host was deployed using vSphere Auto Deploy, you can use vSphere Auto Deploy to reprovision the host with a new image profile that contains a different version of ESX. You can use vSphere ESXi Image Builder to create and manage image profiles. The vSphere Auto Deploy server is automatically upgraded if you upgrade the corresponding vCenter system. Starting with version 6.0, the vSphere Auto Deploy server is always on the same management node as the vCenter system.

For more information, see Install and Configure vSphere Auto Deploy in the ESXi Installation guide:

- vSphere Auto Deploy Boot Process
- Reprovisioning Hosts
- Provision ESX Host with an Image Profile Without VMware Tools

After You Upgrade ESX Hosts

To complete a host upgrade, you ensure that the host is reconnected to its managing vCenter system and reconfigured if necessary. You also check that the host is licensed correctly.

After you upgrade an ESX host, take the following actions:

- View the upgrade logs. You can use the vSphere Client to export the log files.

- If a vCenter system manages the host, you must reconnect the host to vCenter by right-clicking the host in the vCenter inventory and selecting **Connect**.
- When the upgrade is complete, the ESX host is in evaluation mode. The evaluation period is 90 days. Starting with ESX 9.0, you no longer license ESX hosts by using the vSphere Client. After you license the vCenter instance connected to the ESX hosts, they are licensed automatically. For more information, see Licensing Overview in the *Licensing* guide.
- The host sdX devices might be renumbered after the upgrade. If necessary, update any scripts that reference sdX devices.
- Upgrade virtual machines on the host. See Upgrading Virtual Machines and VMware Tools.
- Set up the vSphere Authentication Proxy service. Earlier versions of the vSphere Authentication Proxy are not compatible with vSphere 9.1. See the *vSphere Security* documentation for details about configuring the vSphere Authentication Proxy service.

Licensing ESX Hosts After Upgrade

Starting with ESX 9.0, you no longer license ESX hosts by using the vSphere Client.

After you license the vCenter instance connected to the ESX hosts, they are licensed automatically. For more information, see Licensing Overview in the *Licensing* guide.

Run the Secure Boot Validation Script After ESX Upgrade

After you upgrade an ESX host from a version that does not support UEFI secure boot, you must check if you can activate secure boot.

After you upgrade an ESX host from an older version of ESX that did not support UEFI secure boot, you might be able to activate secure boot. Whether you can activate secure boot depends on how you performed the upgrade and whether the upgrade replaced all the existing VIBs or left some VIBs unchanged. You can run a validation script after you perform the upgrade to determine whether the upgraded installation supports secure boot.

- Verify that the hardware supports UEFI secure boot.
- Verify that all VIBs are signed with an acceptance level of at least PartnerSupported. If you include VIBs at the CommunitySupported level, you cannot use secure boot.

For secure boot to succeed, the signature of every installed VIB must be available on the system. Older versions of ESX do not save the signatures when installing VIBs.

- If you upgrade using ESXCLI commands, the old version of ESX performs the installation of the new VIBs, so their signatures are not saved and secure boot is not possible.
- If you upgrade using the ISO, new VIBs do have their signatures saved. This is true also for vSphere Lifecycle Manager upgrades that use the ISO.
- If old VIBs remain on the system, the signatures of those VIBs are not available and secure boot is not possible.
  - If the system uses a third-party driver, and the VMware upgrade does not include a new version of the driver VIB, then the old VIB remains on the system after upgrade.
  - In rare cases, VMware might drop ongoing development of a specific VIB without providing a new VIB that replaces or obsoletes it, so the old VIB remains on the system after upgrade.

  Note:
  UEFI secure boot also requires an up-to-date bootloader. This script does not check for an up-to-date bootloader.

1. Upgrade the ESX and run the following command.

   ```
   /usr/lib/vmware/secureboot/bin/secureBoot.py -c
   ```

2. Check the output.

   The output either includes `Secure boot can be enabled` or `Secure boot CANNOT be enabled`.

Configure System Logging

ESX hosts run the syslog service (vmsyslogd) that writes messages from system components to log files and can forward messages to syslog collectors. You can configure the amount and location of the logs. You can also create and apply log filters to modify the logging policy of an ESX host.

For configuring the system logs on ESX hosts, see the following topics:

- Configure Syslog on ESX Hosts
- Fine-tune Syslog on ESX Hosts
- ESX Syslog Options
- Protocols, Formats, and Framing of ESX Syslog Messages
- Log File Formats
- ESX Syslog Message Transmission Formats
- Configure Log Filtering on ESX Hosts

When configuring remote hosts for syslog, you also need to open some specified ports in the ESX host firewall to allow the transmission of log messages. For more information, see Opening the firewall for syslog emission to remote hosts.

Collect Logs for Troubleshooting Failed ESX Upgrades

If an installation or upgrade fails, you can collect installation or upgrade log files for ESX that help you identify the source of the failure.

To collect files that help you in troubleshooting failed ESX upgrades, follow these steps:

- Enter the `vm-support` command in the ESX Shell or through SSH.
- Navigate to the `/var/tmp/directory`.
- Retrieve the log files from the `.tgz` file.

vCenter Deployment and Setup

vCenter Deployment and Setup describes how to deploy the VMware vCenter® appliance.

At VMware, we value inclusion. To foster this principle within our customer, partner, and internal community, we create content using inclusive language.

Intended Audience

vCenter Deployment and Setup is for anyone who must install and configure VMware vSphere®. These topics are for experienced Microsoft Windows or Linux system administrators who are familiar with virtual machine technology and data center operations.

Introduction to vSphere Deployment and Setup

The two core components of vSphere are ESX and vCenter. ESX is the virtualization platform on which you can create and run virtual machines and virtual appliances. vCenter is a service that acts as a central administrator for ESX hosts connected in a network. vCenter lets you pool and manage the resources of multiple hosts.

You deploy the vCenter appliance, as a preconfigured virtual machine optimized for running vCenter and associated services. You can deploy the vCenter appliance on ESX hosts or on vCenter instances.

For detailed information about the vCenter deployment process, see vCenter Deployment and Setup.

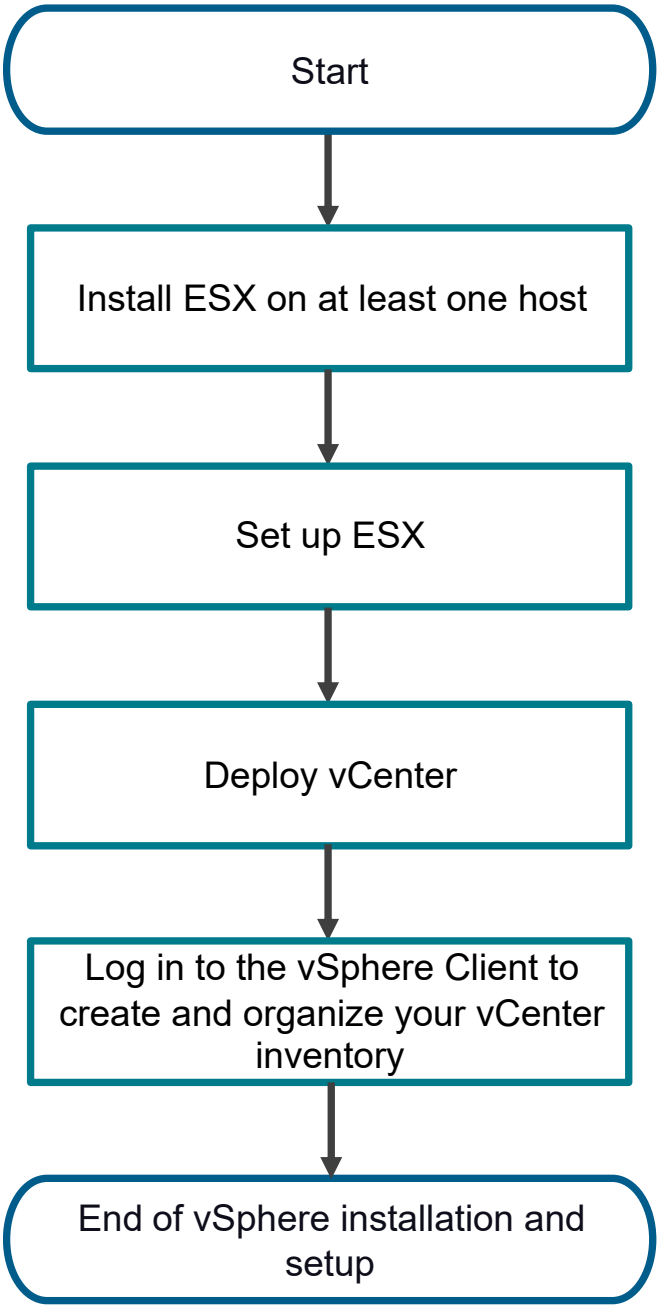
ESX Licensing

Starting with ESX 9.0, you no longer license ESX hosts by using the vSphere Client. For more information on how to license your environment, see Licensing Overview in the *Licensing* guide.

How to Deploy and Set Up vSphere

vSphere is a sophisticated product with multiple components to install and set up. To ensure a successful vSphere deployment, understand the sequence of tasks required.

Figure 13: vSphere Installation and Setup Workflow



Installing vSphere includes the following tasks:

1. Read the vSphere Release Notes.
2. Install ESX.
3. Use the direct console to configure ESX boot and network settings. See VMware ESX Installation and Setup for information.
4. Consider setting up a syslog server for remote logging, to ensure sufficient disk storage for log files. Setting up logging on a remote host is especially important for hosts with limited local storage. See VMware ESX Installation and Setup.
5. Deploy vCenter.
   You can deploy the vCenter appliance on an ESX host.
   1. Review the topics in System Requirements for the vCenter Appliance and verify that your system meets the hardware and software requirements for deploying the appliance.
   2. Determine the deployment method to use.

You can use the GUI method to deploy the appliance interactively. Alternatively, you can use the CLI method to perform a silent deployment of the appliance. See GUI Deployment of the vCenter Appliance and CLI Deployment of the vCenter Appliance.

3. Use the topic Required Information for Deploying a vCenter Appliance to create a worksheet with the information you need for the GUI deployment, or use the topic Prepare Your JSON Configuration File for CLI Deployment to create your JSON templates for the CLI deployment.
4. Deploy the appliance.

6. Connect to vCenter from the vSphere Client. See After You Deploy the vCenter Appliance.
7. Configure the vCenter instance. See vCenter Configuration.

vCenter Components and Services

vCenter provides a centralized platform for management, operation, resource provisioning, and performance evaluation of virtual machines and ESX hosts.

When you deploy the vCenter appliance, vCenter, its components, and the authentication services are deployed on the same system.

The following components are bundled with the vCenter appliance:

- The authentication services include vCenter Single Sign-On, License service, Lookup Service, and VMware Certificate Authority.
- The vCenter group of services includes vCenter, vSphere Client, vSphere Auto Deploy, and vSphere ESX Dump Collector. The vCenter appliance also contains the VMware vSphere Lifecycle Manager Extension service and the VMware vCenter Lifecycle Manager.

Authentication Services

vCenter Single Sign-On

The vCenter Single Sign-On authentication service provides secure authentication services to the vSphere software components. By using vCenter Single Sign-On, the vSphere components communicate with each other through a secure token exchange mechanism, instead of requiring each component to authenticate a user separately with a directory service like Active Directory.

vCenter Single Sign-On can authenticate users through:

- External identity provider federation
  You can configure vCenter for an external identity provider using federated authentication. In such a configuration, you replace vCenter as the identity provider. Currently, vSphere supports Active Directory Federation Services (AD FS) as the external identity provider. In this configuration, AD FS interacts with the identity sources on behalf of vCenter.
- vCenter built-in identity provider
  vCenter includes a built-in identity provider. By default, vCenter uses the vsphere.local domain as the identity source (but you can change it during deployment). You can configure the vCenter built-in identity provider to use Active Directory (AD) as its identity source using LDAP/S, OpenLDAP/S, and Integrated Windows Authentication (IWA). Such configurations allow customers to log in to vCenter using their AD accounts.

Authenticated users can then be assigned registered solution-based permissions or roles within a vSphere environment.

vCenter Single Sign-On is required with vCenter.

vSphere License Service

The vSphere License service provides common license inventory and management capabilities to all vCenter systems within the vCenter Single Sign-On domain.

VMware Certificate Authority

VMware Certificate Authority (VMCA) provisions each ESX host with a signed certificate that has VMCA as the root certificate authority, by default. Provisioning occurs when the ESX host is added to vCenter explicitly or as part of the ESX host installation process. All ESX certificates are stored locally on the host.

For information about all authentication services and capabilities, see vSphere Authentication.

What is the vCenter Appliance

The vCenter appliance is a preconfigured virtual machine that is optimized for running vCenter and the associated services.

The vCenter appliance includes the following software:

- Photon OS® 5.0
- vSphere authentication services
- PostgreSQL
- VMware vSphere Lifecycle Manager Extension
- VMware vCenter Lifecycle Manager

Version 9.1 of vCenter is deployed with virtual hardware version 10, which supports up to 64 virtual CPUs per virtual machine in ESX.

During the deployment, you can choose the vCenter appliance size for your vSphere environment size and the storage size for your database requirements.

vCenter supports high availability. For information about configuring vCenter in a vCenter High Availability cluster, see vSphere Availability.

vCenter supports file-based backup and restore. For information on backing up and restoring, see File-Based Backup and Restore of vCenter.

For information about the vCenter maximums, see VMware Configuration Maximums.

Understanding vSphere Domains and Domain Names

Each vCenter is associated with a vCenter Single Sign-On domain. The domain name defaults to vsphere.local, but you can change it during deployment. The domain determines the local authentication space.

vCenter Single Sign-On Domain

When you deploy a vCenter appliance, you are prompted to create a vCenter Single Sign-On domain or join an existing domain.

The domain name is used by the VMware Directory Service (vmdir) for all Lightweight Directory Access Protocol (LDAP) internal structuring.

You can give your domain a unique name. To prevent authentication conflicts, use a name that is not used by OpenLDAP, Microsoft Active Directory, and other directory services.

After you specify the name of your domain, you can add users and groups. You can add an Active Directory or LDAP identity source and allow the users and groups in that identity source to authenticate. You can also add vCenter instances to the domain.

vCenter Enhanced Linked Mode

vCenter Enhanced Linked Mode (ELM) allows you to log in to any single instance of vCenter and view and manage the inventories of all the vCenter systems in the group.

You can join up to 15 vCenter appliance deployments with vCenter Enhanced Linked Mode in a single vSphere Single Sign-On domain.

You can create a vCenter Enhanced Linked Mode group during the deployment of vCenter appliance.

You can also join a vCenter Enhanced Linked Mode group by moving, or repointing, a vCenter from one vSphere domain to another existing domain. See Repoint vCenter to Another vCenter in a Different Domain for information on repointing a vCenter node.

Note:

With vCenter 9.0, ELM is deprecated and will be removed in a future release. ELM is supported in vCenter 9.0 to allow smooth upgrade of existing infrastructure to VMware Cloud Foundation (VCF), but the recommended alternative is the grouping capability under VCF Operations. Group admins can enable alternatives for each ELM capability, such as vCenter Single Sign-On, consolidated licensing, vCenter roles and privileges sync, vCenter tags replication, and vCenter single API endpoint.

Before you can use new features in 9.0, such as VCF Single Sign-On and vCenter linking, you must deactivate ELM for all vCenter instances in your VCF Instance. For more information about deactivating ELM, see Deactivate Enhanced Link Mode for Standalone vCenter Instances Using the cmsso-util break-elm Utility in the VCF documentation.

For more information on linking vCenter instances, see Linking vCenter Instances in VCF Operation.

vCenter Enhanced Linked Mode for vCenter Appliance

When you enable Enhanced Linked Mode for vCenter appliance deployments, you can connect multiple vCenter appliance deployments together to form a domain.

Other features include:

- A simplified backup and restore process. See File-Based Backup and Restore of vCenter for more information.
- A simplified HA process, removing the need for load balancers.
- Up to 15 vCenter appliance deployments can be linked together using enhanced linked mode and displayed in a single inventory view.
- For a vCenter High Availability (vCenter HA) cluster, three nodes are considered one logical vCenter node. See HA Architecture Overview in *vSphere Availability* for the vCenter HA architecture overview.

Enhanced Linked Mode with Read-Only Replication

If a vCenter High Availability (vCenter HA) instance is connected with another vCenter instance with enhanced linked mode and vCenter HA failover occurs to the passive node and is unable to communicate with its replication partner on the other vCenter node, the replica on the vCenter HA node enters read-only mode.

Joining a vCenter Enhanced Linked Mode Domain

You can join a vCenter appliance to another node during deployment of the vCenter appliance.

Note:

You can also join a vCenter Enhanced Linked Mode group by moving, or repointing, a vCenter from one vSphere domain to another existing domain. See Repoint vCenter to Another vCenter in a Different Domain for information on repointing a vCenter node.

For example, you can deploy two vCenter appliance systems and join the two nodes using vCenter Enhanced Linked Mode.

Before you deploy a new vCenter as part of a vCenter Enhanced Linked Mode, create an image-based backup of the existing nodes in your environment. You can use the backup as a precaution in case there is a failure during the deployment process. It is recommended that you shut down all linked vCenter instances and take offline snapshots to ensure that their databases are in sync during the backup process.

Enhanced Linked Mode requires vCenter instances to be of the same version for database replication to work across the different linked vCenter instances. During the upgrade process, if some of the vCenter instances are of different versions, the Enhanced Link Mode replication features might not work as expected.

If you are deploying the vCenter appliance nodes with the UI Installer:

1. For Appliance 1, deploy the vCenter appliance as an instance on ESX Host 1. Synchronize the time settings with ESX Host 1.

2. For Appliance 2, deploy the vCenter appliance as an instance on ESX Host 1 and configure the time settings so that Appliance 2 is synchronized with ESX Host 1. In stage 2 you select to join the vCenter Single Sign-On domain of the deployed appliance on Appliance 1. For specific instructions, see Stage 2 - Set up the Newly Deployed vCenter Appliance.

If you are deploying the vCenter appliance nodes with the CLI:

1. Configure the JSON configuration template `embedded_vCSA_on_VC.json` (or `embedded_vCSA_on_ESXi.json`) for Appliance 1 as an instance on ESX Host 1. See Prepare Your JSON Configuration File for CLI Deployment for specific instructions on preparing the JSON configuration file.
2. Deploy Appliance 1 by running the `vcsa-cli-installer` command. See Deploy a vCenter Appliance by Using the CLI for instructions.
3. Configure the JSON configuration template `embedded_vCSA_replication_on_VC.json` (or `embedded_vCSA_replication_on_ESXi.json`) for Appliance 2 as an instance on ESX Host 1. Enter the hostname of the first embedded node in the `replication_partner_hostname` field in the `sso` section.
4. Deploy Appliance 2 by running the `vcsa-cli-installer` command using the `embedded_vCSA_replication_on_VC.json` (or `embedded_vCSA_replication_on_ESXi.json`) file.

Deploying the vCenter Appliance

You can deploy the vCenter appliance to manage your vSphere environment.

You can deploy the vCenter appliance on an ESX host 9.0 or later, or on an ESX host or vSphere cluster from the inventory of a vCenter 9.0 instance or later.

For information about the software included in the vCenter appliance 9.1, see What is the vCenter Appliance.

For information about the software and hardware requirements for deploying the vCenter appliance, see System Requirements for the vCenter Appliance.

The vCenter installer contains executable files both for GUI and CLI deployments.

- The GUI deployment is a two stage process. The first stage is a deployment wizard that deploys the OVA file of the appliance on the target ESX host or vCenter instance. After the OVA deployment finishes, you are redirected to the second stage of the process that sets up and starts the services of the newly deployed appliance.
- The CLI deployment method involves running a CLI command against a JSON file that you previously prepared. The CLI installer parses the configuration parameters and their values from the JSON file and generates an OVF Tool command that automatically deploys and sets up the appliance. The CLI deployment automatically runs both stage 1 then stage 2, with no user interaction required.

The vCenter appliance has the following default user names:

User Name	Description
root	Use this user name to log in to the appliance operating system and the vCenter Management Interface. You set the password while deploying the virtual appliance.
administrator@*your_domain_name*	Use this user name for vCenter Single Sign-On login. You set the password while creating the vCenter Single Sign-On domain. You create a vCenter Single Sign-On domain during the deployment of a vCenter appliance in a new vCenter Single Sign-On domain. After you create a vCenter Single Sign-On domain, only the administrator@*your_domain_name* user has the privileges required to log in to vCenter Single Sign-On and vCenter. The administrator@*your_domain_name* user can proceed as follows: • Add an identity source in which additional users and groups are defined to vCenter Single Sign-On. • Give permissions to the users and groups. For information about adding identity sources and giving permissions to the users and groups, see *vSphere Authentication*.

For information about upgrading and patching the vCenter appliance, see vCenter Upgrade.

For information about configuring vCenter, see vCenter Configuration.

If you want to set up vCenter to use an IPv6 address version, use the fully qualified domain name (FQDN) or host name of the appliance. To set up an IPv4 address, the best practice is to use the FQDN or host name of the appliance, because the IP address can change if assigned by DHCP.

System Requirements for the vCenter Appliance

You can deploy the vCenter 9.1 appliance on an ESX 8.0 Update 1 or later hosts, or vCenter 8.0 or later instances. The upgrade of the appliance is a migration of the old version to the new version, which includes deploying a new appliance of version 9.1. Your system must also meet specific software and hardware requirements.

When you use fully qualified domain names (FQDN), verify that the client machine from which you are deploying the appliance and the network on which you are deploying the appliance uses the same DNS server.

Before you deploy the appliance, synchronize the clocks of the target ESX host and all vCenter instances on the vSphere network. Unsynchronized clocks might result in authentication problems and can cause the deployment to fail or prevent the appliance services from starting. See Synchronizing Clocks on the vSphere Network.

See the full list of vCenter system requirements:

- Hardware Requirements for the vCenter Appliance
- Storage Requirements for the vCenter Appliance
- Software Requirements for the vCenter Appliance
- DNS Requirements for the vCenter Appliance
- Required Ports for vCenter
- vSphere Client Software Requirements

Hardware Requirements for the vCenter Appliance

When you deploy or upgrade the vCenter appliance, you can select an appliance size suitable for your vSphere environment. The option that you select determines the number of CPUs and the amount of memory for the appliance.

The hardware requirements for a vCenter appliance depend on the size of your vSphere inventory.

	Number of vCPUs	Memory
Tiny environment (up to 10 hosts or 100 virtual machines)	2	14 GB
Small environment (up to 100 hosts or 1,000 virtual machines)	4	21 GB
Medium environment (up to 400 hosts or 4,000 virtual machine)	8	30 GB
Large environment (up to 1,000 hosts or 10,000 virtual machines)	16	39 GB
X-Large environment (up to 2,000 hosts or 35,000 virtual machines)	24	58 GB

Note:
If you want to add an ESX host with more than 512 LUNs and 2,048 paths to the vCenter inventory, you must deploy a vCenter appliance for a large or x-large environment.

Storage Requirements for the vCenter Appliance

When you deploy or upgrade the vCenter appliance, the ESX host or DRS cluster on which you deploy the appliance must meet minimum storage requirements. The required storage depends not only on the size of the vSphere environment and the storage size, but also on the disk provisioning mode.

The storage requirements are different for each vSphere environment size and depend on your database size requirements.

	Default Storage Size	Large Storage Size	X-Large Storage Size
Tiny environment • up to 10 hosts or 100 virtual machines	619 GB	2059 GB	4319 GB
Small environment • up to 100 hosts or 1,000 virtual machines	734 GB	2084 GB	4344 GB
Medium environment • up to 400 hosts or 4,000 virtual machine	933 GB	2233 GB	4493 GB
Large environment • up to 1,000 hosts or 10,000 virtual machines	1383 GB	2283 GB	4543 GB
X-Large environment • up to 2,000 hosts or 35,000 virtual machines with default and large storage • up to 2,500 hosts or 45,000 virtual machines with X-Large storage	2308 GB	2408 GB	4668 GB

For more information on disk provisioning, see Storage Provisioning and Space Reclamation in vSphere.

Note:
The storage requirements include the requirements for the vSphere Lifecycle Manager that runs as a service in the vCenter appliance.

Software Requirements for the vCenter Appliance

The vCenter 9.1 appliance can be deployed on ESX 8.0 Update 1 or later hosts, or on vCenter 8.0 or later instances or later.

You can deploy the vCenter 9.1 appliance using the GUI or CLI installer. You run the installer from a client machine that you use to connect to the target ESX host and deploy the appliance on the server. You can connect directly to an ESX 8.0 Update 1 or later host on which to deploy the appliance. You can also connect to a vCenter 8.0 or later instance to deploy the appliance on an ESX host or vCenter managed cluster that resides in the vCenter inventory.

For information about the requirements for network client machine, see System Requirements for the vCenter Installer.

DNS Requirements for the vCenter Appliance

When you deploy the vCenter appliance, similar to any network server, you can assign a fixed IP address and an FQDN that is resolvable by a DNS server so that clients can reliably access the service.

When you deploy the vCenter appliance with a static IP address, you ensure that in case of system restart, the IP address of the appliance remains the same.

Before you deploy the vCenter appliance with a static IP address, you must verify that this IP address has a valid internal domain name system (DNS) registration.

When you deploy the vCenter appliance, the configuration of the web server component that supports the vSphere Client fails if the installer cannot look up the fully qualified domain name (FQDN) for the appliance from its IP address. Reverse lookup is implemented using PTR records.

If you plan to use an FQDN for the appliance system name, you must verify that the FQDN is resolvable by a DNS server, by adding forward and reverse DNS A records.

After the vCenter upgrade, the appliance frees this static IP address and assumes the network settings of the old appliance.

Important:

To avoid upgrade or install failures in vSphere 9.1.x, your DNS server must comply with RFC 4074 behavior for negative `AAAA` responses. The DNS server must return `RCODE = 0` and an empty answer section for `AAAA` queries when there is no IPv6 record, rather than `NXDOMAIN` or other errors. See the Broadcom Knowledge Base article: 377682.

You can use the `nslookup` command to verify that the DNS reverse lookup service returns an FQDN when queried with the IP address and to verify that the FQDN is resolvable.

```
nslookup -nosearch -nodefname FQDN_or_IP_address
```

If you use DHCP instead of a static IP address for the vCenter appliance, verify that the appliance name is updated in the domain name service (DNS). If you can ping the appliance name, the name is updated in DNS.

Ensure that the ESX host management interface has a valid DNS resolution from the vCenter and all vSphere Client instances. Ensure that the vCenter has a valid DNS resolution from all ESX hosts and vSphere Client.

vSphere Client Software Requirements

Use of the vSphere Client requires a supported web browser.

VMware has tested and supports the following guest operating systems and browser versions for the vSphere Client.

Supported Guest Operating Systems	• Windows 32-bit and 64-bit • Mac OS • Linux
Supported Browser Versions	• Google Chrome 120 or later • Mozilla Firefox 115 or later • Microsoft Edge 120 or later

Note:
Later versions of these browsers are likely to work, but have not been tested.

Preparing for Deployment of the vCenter Appliance

Before you deploy the vCenter appliance, you must download the vCenter installer ISO file and mount it to a network virtual machine or physical server from which you want to perform the deployment.

The machine from which you deploy the appliance must run on a Windows, Linux, or Mac operating system that meets the operating system requirements. See System Requirements for the vCenter Installer.

- Synchronizing Clocks on the vSphere Network

System Requirements for the vCenter Installer

You can run the vCenter GUI or CLI installer from a client machine that is running on a Windows, Linux, or Mac operating system of a supported version.

To ensure optimal performance of the GUI and CLI installers, use a client machine that meets the minimum hardware requirements.

Table 33: System Requirements for the GUI and CLI Installers

Operating System	Supported Versions	Minimum Hardware Configuration for Optimal Performance
Windows	• Windows 11 • Windows 2022 • Windows 2025	4 GB RAM, 2 CPU having 4 cores with 2.3 GHz, 32 GB hard disk, 1 NIC
Linux	• SUSE 15.6 • Ubuntu 22.04, 24.04	4 GB RAM, 1 CPU having 2 cores with 2.3 GHz, 16 GB hard disk, 1 NIC **Note:** The CLI installer requires 64-bit OS.
Mac	• macOS 13, 14, 15	8 GB RAM, 1 CPU having 4 cores with 2.4 GHz, 150 GB hard disk, 1 NIC

Note:
For client machines that run on Mac 13 or later, concurrent GUI deployments of multiple appliances are unsupported. You must deploy the appliances in sequence.

Note:
Deploying the vCenter appliance with the GUI requires a minimum resolution of 1024x768 to properly display. Lower resolutions can truncate the UI elements.

Download and Mount the vCenter Installer

The vCenter appliance ISO image contains GUI and CLI installers for the vCenter appliance.

- Access to the Broadcom Support Portal.
- Verify that your client machine meets the system requirements for the vCenter installer. See System Requirements for the vCenter Installer.

With the GUI and CLI executable files that are included in the vCenter installer, you can:

- Deploy the vCenter appliance.
- Upgrade the vCenter appliance.
- Restore a vCenter appliance from a file-based backup.

1. Log in to the Broadcom Support Portal.
2. Download the vCenter appliance ISO image. See Broadcom knowledge base article 366685.
3. Confirm that the md5sum is correct by using an MD5 checksum tool.
4. Mount the ISO image to the client machine from which you want to deploy, upgrade, or restore the appliance.

   Note:
   ISO mounting software that does not allow more than eight directory levels, for example, MagicISO Maker on Windows, is unsupported.

   For Linux OS and Mac OS, Archive Manager is unsupported.

   For Mac OS, you can use DiskImageMounter.

   For Ubuntu 22.04 and 24.04, you can use Disk Image Mounter.

   For SUSE 15.6 OS, you can use the terminal.

   ```
   $ sudo mkdir mount_dir
   $ sudo mount -o loop VMware-vCSA-all-version_number-build_number.iso mount_dir
   ```

Open the `readme.txt` file and review the information about the other files and directories in the vCenter appliance ISO image.

Synchronizing the Client and Server System Clock

To establish a secure TLS connection to a vCenter appliance, the system where you are running the CLI installer (the client) must not have its system clock slower or faster than the server's system clock by an acceptable limit (tolerance).

See Table 34: Client Clock Tolerance for specific values for each deployment scenario.

Note:

The client clock values are applicable only for vCenter 9.0 and later.

Table 34: Client Clock Tolerance

Deployment Scenario	Clock Tolerance
Linking one vCenter with another vCenter	When deploying the second vCenter, the clock tolerance for the client and the first vCenter must not exceed 10 minutes.
Installing a vCenter appliance using a container vCenter with a `*._on_vc.json` template.	The maximum clock tolerance between the client and the container vCenter is 8 hours 20 minutes.

Prerequisites for Deploying the vCenter Appliance

To ensure a successful deployment of the vCenter appliance, you must perform some required tasks and pre-checks before running the installer.

General Prerequisites

- Download and Mount the vCenter Installer.

Target System Prerequisites

- Verify that your system meets the minimum software and hardware requirements. See System Requirements for the vCenter Appliance.
- If you want to deploy the appliance on an ESX host, verify that the ESX host is not in lockdown or maintenance mode and not part of a fully automated vSphere cluster.
- If you want to deploy the appliance on a vSphere cluster of the inventory of a vCenter instance, verify that the cluster contains at least one ESX host that is not in lockdown or maintenance mode.
- If you plan to use NTP servers for time synchronization, verify that the NTP servers are running and that the time between the NTP servers and the target server on which you want to deploy the appliance is synchronized.
- If you want to deploy the appliance on a vSAN ESA cluster with vSAN ESA encryption, you must enable vSAN ESA encryption before installing vCenter. vSAN Express Storage Architecture is a next-generation architecture designed to get the most out of high-performance storage devices, resulting in greater performance and efficiency. You can enable vSAN ESA encryption through vSAN SDK or vSAN API.

vCenter Enhanced Linked Mode Prerequisites

When deploying a new vCenter as part of an Enhanced Linked Mode deployment, create an image-based backup of the existing vCenter nodes in your environment. You can use the backup as a precaution in case there is a failure during the deployment process.

If the deployment fails, delete the newly deployed vCenter appliance, and restore the vCenter nodes from their respective image-based backups. You must restore all the nodes in the environment from their image-based backups. Failing to do so can cause the replication partners to be out of synchronization with the restored node.

- To learn more about creating vCenter Enhanced Linked Mode deployments, see vCenter Enhanced Linked Mode.
- To learn about image-based backs, see Image-Based Backup and Restore of a vCenter Environment.

Network Prerequisites

If you plan to assign a static IP address and an FQDN as a system name in the network settings of the appliance, verify that you have configured the forward and reverse DNS records for the IP address.

GUI Deployment of the vCenter Appliance

You can use the GUI installer to perform an interactive deployment of a vCenter appliance.

When you perform the GUI deployment, you download the vCenter installer on a client machine, run the deployment wizard from the client machine, and provide the inputs that are required for the appliance deployment and setup.

The GUI deployment process includes a series of two stages.

Figure 14: Stage 1 - OVA Deployment

The first stage walks you through the deployment wizard to choose the deployment type and appliance settings. This stage completes the deployment of the OVA file on the target ESX host with the deployment type and appliance settings that you provide.

As an alternative to performing the first stage of the deployment with the GUI installer, you can deploy the OVA file of the vCenter appliance by using the vSphere Client. After the OVA deployment, you must log in to the vCenter Management Interface of the newly deployed appliance to proceed with the second stage of the deployment process. See Deploy and Export OVF and OVA Templates in *vSphere Virtual Machine Administration* for information about deploying an OVA file using the vSphere Client.

Figure 15: Stage 2 - Appliance Setup

The second stage walks you through the setup wizard to configure the appliance time synchronization and vCenter Single Sign-On. This stage completes the initial setup and starts the services of the newly deployed appliance.

As an alternative to performing the second stage of the deployment with the GUI installer, you can log in to the vCenter Management Interface of the newly deployed appliance, https://`vcenter_IP_address_or_fqdn`:5480.

Required Information for Deploying a vCenter Appliance

When you use the GUI method to deploy a vCenter appliance, the wizard prompts you for deployment and setup information. It is a best practice to keep a record of the values that you enter in case you must reinstall the product.

You can use this worksheet to record the information that you need for deploying a vCenter appliance.

Table 35: Required Information During Stage 1 of the GUI Deployment Process

Required Information	Default	Your Entry
FQDN or IP address of the target server on which you want to deploy the appliance. The target server can be either an ESX host or a vCenter instance.	-	
HTTPS port of the target server	443	

Required Information	Default	Your Entry
User name with administrative privileges on the target server • If your target server is an ESX host, use root. • If your target server is a vCenter instance, use *user_name*@*your_domain_name*, for example, administrator@vsphere.local.	-	
Password of the user with administrative privileges on the target server	-	
Data center from the vCenter inventory on which you want to deploy the appliance. Target server must be a vCenter instance. Optionally you can provide a data center folder.	-	
ESX host or DRS cluster from the data center inventory on which you want to deploy the appliance.	-	
VM name for the appliance: • Must not contain a percent sign (%), backslash (\), or forward slash (/). • Must be no more than 80 characters in length.	vCenter	
Password for the root user of the appliance operating system • Must be at least 8 characters, but no more than 20 characters in length. • Must contain at least one uppercase letter. • Must contain at least one lowercase letter. • Must contain at least one number. • Must contain at least one special character, for example, a dollar sign ($), hash key (#), at sign (@), period (.), or exclamation mark (!).	-	
Deployment size of the vCenter appliance for your vSphere environment. See Hardware Requirements for the vCenter Appliance for information about the deployment sizes you can select. The option that you select determines the number of CPUs and the amount of memory for the appliance.	Tiny	
Storage size of the vCenter appliance for your vSphere environment. The required storage depends not only on the size of the vSphere environment, but also on the disk provisioning mode. See Storage Requirements for the vCenter Appliance. Increase the default storage size if you want larger volume for SEAT data (stats, events, alarms, and tasks).	Default	
Name of the datastore on which you want to store the configuration files and virtual disks of the appliance. **Note:** The installer displays a list of datastores that are accessible from your target server.	-	
Activate or deactivate Thin Disk Mode.	Deactivated	

Required Information	Default	Your Entry
Name of the network to which to connect the appliance **Note:** The installer displays a drop-down menu with networks that depend on the network settings of your target server. If you are deploying the appliance directly on an ESX host, non-ephemeral distributed virtual port groups are not supported and are not displayed in the drop-down menu. The network must be accessible from the client machine from which you perform the deployment.	-	
IP version for the appliance address Can be either IPv4 or IPv6.	IPv4	
IP assignment for the appliance address Can be either static or DHCP.	static	
FQDN For a static IP assignment vCenter uses FQDN or IP address as the system name.	-	
IP address	-	
For IPv4 networks, you can use either a subnet mask or a network prefix. Subnet mask uses a dot decimal notation (for example, 255.255.255.0). An IPv4 network prefix is an integer between 0 and 32. For IPv6 networks, you must use a network prefix. An IPv6 network prefix is an integer between 0 and 128.	-	
Default gateway	-	
DNS servers separated by commas	-	
System name (FQDN) Only if you use DHCP with IPv4 and have a Dynamic DNS (DDNS) server available in your environment.	-	

Table 36: Required Information During Stage 2 of the GUI Deployment Process

Required Information	Default	Your Entry
Time synchronization settings You can synchronize the time of the appliance either with the time of the ESX host or with one or more NTP servers. If you want to use more than one NTP servers, you must provide the IP addresses or FQDNs of the NTP servers as a comma-separated list.	Synchronize time with NTP servers	
Activate or deactivate SSH access **Note:** vCenter High Availability requires remote SSH access to the appliance.	Deactivate	
Name for the new vCenter Single Sign-On domain For example, vsphere.local.	-	

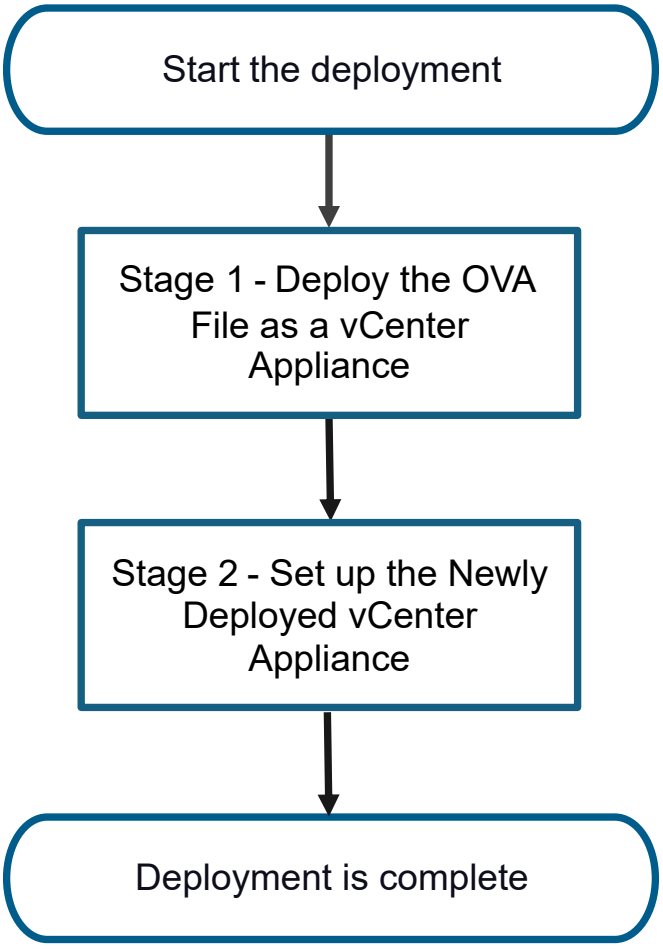
Required Information	Default	Your Entry
Password for the administrator account, administrator@*your_domain_name* • Must be at least 8 characters, but no more than 20 characters in length. • Must contain at least one uppercase letter. • Must contain at least one lowercase letter. • Must contain at least one number. • Must contain at least one special character, such as ampersand (&), hash key (#), and percent sign (%).	-	
Password of the vCenter Single Sign-On administrator user for the domain.	-	
Join or do not participate in the VMware Customer Experience Improvement Program (CEIP). For information about the CEIP, see the Configuring Customer Experience Improvement Program section in *vCenter and Host Management*.	Join the CEIP	

Deploy the vCenter Appliance by Using the GUI

You can use the GUI installer to perform an interactive deployment of a vCenter appliance. You must run the GUI deployment from a Windows, Linux, or Mac machine that is in the network on which you want to deploy the appliance.

- See Prerequisites for Deploying the vCenter Appliance.
- See Required Information for Deploying a vCenter Appliance.

Figure 16: Deployment Workflow of a vCenter Appliance



Stage 1 - Deploy the OVA File as a vCenter Appliance

With stage 1 of the deployment process, you deploy the OVA file, which is included in the vCenter installer ISO, as a vCenter appliance.

1. In the vCenter installer, navigate to the `vcsa-ui-installer` directory, go to the subdirectory for your operating system, and run the installer executable file.
   - For Windows OS, go to the `win32` subdirectory, and run the `installer.exe` file.
   - For Linux OS, go to the `lin64` subdirectory, and run the `installer` file.
   - For Mac OS, go to the `mac` subdirectory, and run the `Installer.app` file.
2. On the Home page, click **Install** to start the deployment wizard.
3. Review the Introduction page to understand the deployment process and click **Next**.
4. Read and accept the license agreement, and click **Next**.
5. Connect to the target server on which you want to deploy the vCenter appliance.

Option	Steps
You can connect to an ESX host on which to deploy the appliance.	1. Enter the FQDN or IP address of the ESX host. 2. Enter the HTTPS port of the ESX host. 3. Enter the user name and password of a user with administrative privileges on the ESX host, for example, the root user. 4. Click **Next**. 5. Verify that the certificate warning displays the SHA1 thumbprint of the SSL certificate that is installed on the target ESX host, and click **Yes** to accept the certificate thumbprint.
You can connect to a vCenter instance and browse the inventory to select an ESX host or DRS cluster on which to deploy the appliance.	1. Enter the FQDN or IP address of the vCenter instance. 2. Enter the HTTPS port of the vCenter instance. 3. Enter the user name and password of user with vCenter Single Sign-On administrative privileges on the vCenter instance, for example, the administrator@*your_domain_name* user. 4. Click **Next**. 5. Verify that the certificate warning displays the SHA1 thumbprint of the SSL certificate that is installed on the target vCenter instance, and click **Yes** to accept the certificate thumbprint. 6. Select the data center or data center folder that contains the ESX host or DRS cluster on which you want to deploy the appliance, and click **Next** **Note:** You must select a data center or data center folder that contains at least one ESX host that is not in lockdown or maintenance mode. 7. Select the ESX host or DRS cluster on which you want to deploy the appliance, and click **Next**.

6. On the Set up appliance VM page, enter a name for the vCenter appliance, set the password for the root user, and click **Next**.

   The appliance name must not contain a percent sign (%), backslash (\), or forward slash (/) and must be no more than 80 characters in length.

   The password must contain only lower ASCII characters without spaces, at least eight characters, a number, uppercase and lowercase letters, and a special character, for example, an exclamation mark (!), hash key (#), at sign (@), or brackets (()).

7. Select the deployment size for the vCenter appliance for your vSphere inventory.

   See Hardware Requirements for the vCenter Appliance for information about the deployment sizes you can select. The option that you select determines the number of CPUs and the amount of memory for the appliance.

8. Select the storage size for the vCenter appliance, and click **Next**.

   The required storage depends not only on the size of the vSphere environment, but also on the disk provisioning mode. See Storage Requirements for the vCenter Appliance.

9. Select the storage location for the vCenter appliance where all the virtual machine configuration files and virtual disks will be stored.

Option	Action
Install on an existing datastore accessible from the target host	Select a datastore from the list of compatible datastores.
Install on a new vSAN cluster containing the target host	Specify the required details to create a new vSAN cluster or a vSAN Express Storage Architecture (vSAN ESA) cluster to store the vCenter appliance.
Install on an existing vSAN datastore and claim additional disks	Specify the required details to create a cluster on the vSAN datastore. This option is displayed only if your environment contains a vSAN datastore.

   To enable thin provisioning, select **Enable Thin Disk Mode**. NFS datastores are thin provisioned by default.

10. Optional: If you selected vSAN as your storage location, you must claim disks for storage.
    - For vSAN, claim disks separately for cache tier and capacity tier.
    - For vSAN ESA, claim disks from the list of compatible disks.

11. On the Configure network settings page, set up the network settings.

    The IP address or the FQDN of the appliance is used as a system name. It is recommended to use an FQDN. However, if you want to use an IP address, use static IP address allocation for the appliance, because IP addresses allocated by DHCP might change.

Option	Action
Network	Select the network to which to connect the appliance. The networks displayed in the drop-down menu depend on the network settings of the target server. If you are deploying the appliance directly on an ESX host, non-ephemeral distributed virtual port groups are not supported and are not displayed in the drop-down menu.
IP version	Select the version for the appliance IP address. You can select either IPv4 or IPv6.
IP assignment	Select how to allocate the IP address of the appliance. • **static** The wizard prompts you to enter the IP address and network settings. • **DHCP** A DHCP server is used to allocate the IP address. Select this option only if a DHCP server is available in your environment. If there is an enabled DDNS in your environment, you can enter a preferred fully qualified domain name (FQDN) for the appliance.
Common Ports	You can customize the HTTP and HTTPS ports (optional). If specifying a custom HTTP and HTTPS port number, ensure that you do not use a port number already in use by vCenter , or the default HTTP and HTTPS ports of 80 and 443.

Option	Action
	Note: 1. You can only customize the HTTP and HTTPS ports during installation. You cannot customize any other port. 2. You cannot change any port after installation. 3. Upgrade or migration procedures persist all port configuration. Port customizations that were previously supported in Windows OS deployments are persisted in a Windows to Linux migration.

12. On the Ready to complete stage 1 page, review the deployment settings for the vCenter appliance and click **Finish** to start the OVA deployment process.
13. Wait for the OVA deployment to finish, and click **Continue** to proceed with stage 2 of the deployment process to set up and start the services of the newly deployed appliance.

    Note:
    If you exit the wizard by clicking **Close**, you must log in to the vCenter Management Interface to set up and start the services.

The newly deployed vCenter appliance is running on the target server but the services are not started.

Stage 2 - Set up the Newly Deployed vCenter Appliance

When the OVA deployment finishes, you are redirected to stage 2 of the deployment process to set up and start the services of the newly deployed vCenter appliance.

1. Review the introduction to stage 2 of the deployment process and click **Next**.
2. Configure the time settings in the appliance, optionally enable remote SSH access to the appliance, and click **Next**.

Option	Description
Synchronize time with the ESX host	Enables periodic time synchronization, and VMware Tools sets the time of the guest operating system to be the same as the time of the ESX host.
Synchronize time with NTP servers	Uses a Network Time Protocol server for synchronizing the time. If you select this option, you must enter the names or IP addresses of the NTP servers separated by commas.

3. Create a new vCenter Single Sign-On domain or join an existing domain.

Option	Description
Create a new Single Sign-On domain	Creates a new vCenter Single Sign-On domain. 1. Enter the domain name, for example `vsphere.local`. **Note:** Ensure that the domain name does not contain any upper-case letters. 2. Set the password for the vCenter Single Sign-On administrator account. This is the password for the user administrator@*`your_domain_name`*. 3. Confirm the administrator password, and click **Next**.
Join an existing Single Sign-On domain	Joins a new vCenter Single Sign-On server to an existing vCenter Single Sign-On domain. You must provide the information about the vCenter Single Sign-On server to which you join the new vCenter Single Sign-On server. 1. Enter the fully qualified domain name (FQDN) or IP address of the vCenter Single Sign-On server to join.

Option	Description
	2. Enter the HTTPS port to use for communication with the vCenter Single Sign-On server. 3. Enter the domain name for the vCenter Single Sign-On you are joining, for example `vsphere.local`. 4. Enter the password of the vCenter Single Sign-On administrator account. 5. Click **Next**.

When you select to join an existing vCenter Single Sign-On domain, you enable the Enhanced Linked Mode feature. The infrastructure data is replicated with the joined vCenter Single Sign-On server.

4. Review the VMware Customer Experience Improvement Program (CEIP) page and choose if you want to join the program.

   For information about the CEIP, see the Configuring Customer Experience Improvement Program section in *vCenter and Host Management*.

5. On the Ready to complete page, review the configuration settings for the vCenter appliance, click **Finish**, and click **OK** to complete stage 2 of the deployment process and set up the appliance.

6. Optional: After the initial setup finishes, enter the URL from the browser with **https://*vcenter_IP_address_or_fqdn*/ui** to go to the vSphere Client and log in to the vCenter instance in the vCenter appliance, or click the **https://*vcenter_IP_address_or_fqdn*:443** to go the vCenter appliance Getting Started page.

7. Click **Close** to exit the wizard.

   You are redirected to the vCenter appliance Getting Started page.

You can configure high availability for the vCenter appliance. For information about providing vCenter appliance high availability, see *vSphere Availability*.

CLI Deployment of the vCenter Appliance

You can use the CLI installer to perform a silent deployment of a vCenter appliance on an ESX host or vCenter instance.

The CLI deployment process includes downloading the vCenter installer on a client machine or physical server from which you want to perform the deployment, preparing a JSON configuration file with the deployment information, and running the deployment command.

Prepare Your JSON Configuration File for CLI Deployment

Before you run the CLI installer to deploy a vCenter appliance, you must prepare a JSON file with configuration parameters and their values for your deployment specification.

- You must be familiar with the JSON syntax.
- Download and Mount the vCenter Installer.

The vCenter installer contains JSON templates for all deployment options. For information about the templates, see JSON Templates for CLI Deployment of the vCenter Appliance.

You can deploy an appliance with minimum configurations by setting values to the configuration parameters in the JSON template for your specification. You can edit the preset values, remove configuration parameters, and add configuration parameters for custom configurations.

For a complete list of the configuration parameters and their descriptions, navigate to the installer subdirectory for your operating system and run the `vcsa-deploy install --template-help` command or see Deployment Configuration Parameters.

1. In the vCenter installer ISO, navigate to the `vcsa-cli-installer` directory, and open the `templates` subfolder.
2. Copy the deployment templates from the `install` subfolder to your workspace.

   Important:
   The path to the JSON configuration files must contain only ASCII characters. Extended ASCII and non-ASCII characters are unsupported.
3. In a text editor, open the template file for your specification.

   To ensure the correct syntax of your JSON configuration file, use a JSON editor.
4. Fill in the values for the required configuration parameters and, optionally, enter additional parameters and their values.
   For example, if you want to use an IPv4 DHCP assignment for the network of the appliance, in the `network` subsection of the template, change the value of the `mode` parameter to `dhcp` and remove the default configuration parameters that are for a static assignment.

   ```
   "network": {
       "ip_family": "ipv4",
       "mode": "dhcp"
   },
   ```

   Important:

   The string values, including the passwords, must contain only ASCII characters. Extended ASCII and non-ASCII characters are unsupported.

   To set a value that contains a backslash (\) or quotation mark (") character, you must precede the character with the backslash (\) character. For example, `"password":"my\"password"` sets the password my"password, `"image":"G:\\vcsa\\VMware-vCenter-Server-Appliance-9.1.1.XXXX-YYYYYYY_OVF10.ova"` sets the path `G:\vcsa\VMware-vCenter-Server-Appliance-9.1.1.XXXX-YYYYYYY_OVF10.ova`.

   The Boolean values must contain only lowercase characters, that is, a value can be either `true` or `false`. For example, `"ssh_enable":false`.
5. Optional: Use a JSON editor of your choice to validate the JSON file.
6. Save in UTF-8 format and close the file.

You can create and save additional templates if needed for your deployment specification.

JSON Templates for CLI Deployment of the vCenter Appliance

The vCenter installer ISO includes JSON templates with the minimum configuration parameters for all deployment options. The templates are located in the `vcsa-cli-installer/templates/install` directory.

For each deployment option, there is one template for deploying the appliance on an ESX host and another template for deploying the appliance on a vCenter instance.

Table 37: Deployment JSON Templates Included in the vCenter Installer

Template	Description
`embedded_vCSA_on_ESXi.json`	Contains the minimum configuration parameters that are required for the deployment of a vCenter appliance on an ESX host.
`vCSA_with_cluster_on_ESXi.json`	Contains the minimum configuration parameters that are required for the deployment of a vCenter appliance with a single node vSAN and a vLCM managed cluster on an ESX host.
`embedded_vCSA_on_VC.json`	Contains the minimum configuration parameters that are required for the deployment of a vCenter appliance on a vCenter instance.

Template	Description
embedded_vCSA_replication_on_ESXi.json	Contains the minimum configuration parameters that are required for the deployment of a vCenter appliance as a replication partner to another embedded vCenter on an ESX host.
embedded_vCSA_replication_on_VC.json	Contains the minimum configuration parameters that are required for the deployment of a vCenter appliance replication partner to another vCenter appliance on a vCenter instance.

Deployment Configuration Parameters

When you prepare your JSON configuration files for a CLI deployment, you must set parameters and values to provide input data for the deployment of a vCenter appliance.

Sections and Subsections of Configuration Parameters in the JSON Deployment Files

The configuration parameters in the JSON configuration files for a CLI upgrade are organized in sections and subsections.

Table 38: Sections and Subsections of Configuration Parameters in the JSON Deployment Files

Section	Subsection	Description
new_vcsa - describes the appliance that you want to deploy	esxi	Use only if you want to deploy the appliance directly on an ESX host. Contains the configuration parameters that describe the target ESX host. Depending on whether you want to configure a vSAN or a vSphere Lifecycle Manager managed cluster during the deployment, see the relevant section for a detailed information about the configuration parameters. • Table 39: Configuration Parameters in the new_vcsa Section, esxi Subsection for Deployments with a vSAN and a vSphere Lifecycle Manager Cluster • Table 40: Configuration Parameters in the new_vcsa Section, esxi Subsection for Deployments without a vSAN and a vSphere Lifecycle Manager Cluster **Note:** You must fill in either the esxi or the vc subsection.
	vc	Use only if you want to deploy the appliance on the inventory of a vCenter instance. Contains the configuration parameters that describe the target ESX host or DRS cluster from the vCenter inventory. See Table 41: Configuration Parameters in the new_vcsa Section, vc Subsection. **Note:** You must fill in either the vc or the esxi subsection.
	appliance	Contains the configuration parameters that describe the appliance. See Table 42: Configuration Parameters in the new_vcsa Section, appliance Subsection.
	install_parameters	Optional subsection for the prefix base MAC address allocation options. See Configuration Parameters in the new_vcsa Section, install_parameters Subsection.
	network	Contains the configuration parameters that describe the network settings for the appliance. See Table 44: Configuration Parameters in the new_vcsa Section, network Subsection.
	os	Contains the configuration parameters that describe the operating system settings for the appliance. See Table 46: Configuration Parameters in the new_vcsa Section, os Subsection.
	sso	Contains the configuration parameters that describe the vCenter Single Sign-On settings for the appliance. See Table 47: Configuration Parameters in the new_vcsa Section, sso Subsection.

Section	Subsection	Description
	`ovftool_arguments`	Optional subsection for adding arbitrary arguments and their values to the OVF Tool command that the installer generates. **Important:** The vCenter installer does not validate the configuration parameters in the `ovftool_arguments` subsection. If you set arguments that the OVF Tool does not recognize, the deployment might fail.
`ceip` - describes joining the VMware Customer Experience Improvement Program (CEIP)	`settings`	Contains only the `ceip_enabled` configuration parameter to join or not to join the VMware Customer Experience Improvement Program (CEIP). See Table 48: Configuration Parameters in the ceip Section, settings Subsection. **Note:** If set to `true`, you must run the CLI deployment command with the `--acknowledge-ceip` argument. For information about the CEIP, see the Configuring Customer Experience Improvement Program section in *vCenter and Host Management*.

Important:

The string values, including the passwords, must contain only ASCII characters. Extended ASCII and non-ASCII characters are unsupported.

To set a value that contains a backslash (\) or a quotation mark (") character, you must precede the character with the backslash (\) character. For example, `"password":"my\"password"` sets the password my"password. Similarly, `"image":"G:\\vcsa\\VMware-vCenter-Server-Appliance-8.0.0.XXXX-YYYYYYY_OVF10.ova"` sets the path `G:\vcsa\VMware-vCenter-Server-Appliance-8.0.0.XXXX-YYYYYYY_OVF10.ova`.

Boolean values must contain only lowercase characters. It must be either `true` or `false`. For example, `"ssh_enable":false`.

Configuration Parameters in the `new_vcsa` Section

Table 39: Configuration Parameters in the `new_vcsa` Section, `esxi` Subsection for Deployments with a vSAN and a vSphere Lifecycle Manager Cluster

Name	Type	Description
`hostname`	string	The IP address or FQDN of the target ESX host on which you want to deploy the appliance.
`username`	string	A user name with administrative privileges on the target ESX host, for example, root.
`password`	string	The password of the user with administrative privileges on the target ESX host.
`deployment_network`	string	The name of the network to which to connect the appliance. **Note:** The network must be accessible from the target ESX host. Ignored if the target ESX host has only one network.
`datacenter`	string	A specific data center that you want to create.
`cluster`	string	The name of the vSAN or vSphere Lifecycle Manager managed cluster.
`compression_only`	Boolean	Set the value to `true` to enable compression on the vSAN cluster. If this parameter is set to `true`, the `deduplication_and_compression` parameter must be set to`false`.
`deduplication_and_compression`	Boolean	Set the value to `true` to enable compression and deduplication on the vSAN cluster. If this parameter is set to `true`, the `compression_only` parameter must be set to `false`.

Name	Type	Description
`cache_disk`		A list of UUIDs or canonical names of disks you want to use for cache. Specify only SSDs.
`capacity_disk`		A list of UUIDs or canonical names of disks you want to use for storage. Specify either SSDs or HDDs.
`enable_vlcm`	Boolean	Set to `true`. **CAUTION:** Do not modify the value to `false`. The default type of cluster created is a vSphere Lifecycle Manager managed cluster. Setting this field to `false` results in failure during cluster creation.
`enable_vsan_esa`	Boolean	Set to `true` to create a vSAN cluster with vSAN ESA enabled. vSAN Express Storage Architecture is a next-generation architecture that is designed to get the most out of high-performance storage devices, resulting in greater performance and efficiency.
`single_tier`	Array	A list of UUIDs or canonical names of disks you want to add to a vSAN storage pool. Required only if you set `enable_vsan_esa` to `true`.
`vsan_hcl_database_path`	String	Local vSAN HCL database path. If the vSAN HCL database present in this location is outdated, the installer will download and replace the older version with the latest version. Required only if you set `enable_vsan_esa` to `true`.
`datastore`	string	The name of the datastore where you want to store the configuration files and virtual disks of the appliance. **Note:** The datastore must be accessible from the ESX host. If you are using the thin disk mode, the datastore size should have a minimum of 25-GB space.
`port`	integer	The HTTPS reverse proxy port of the target ESX host. The default port is 443. Use only if the target ESX host uses a custom HTTPS reverse proxy port.

`ssl_certificate_verification`	string	The CLI verifies that a server's security certificate is signed by a Certificate Authority (CA), and establishes a secure connection. If the certificate is self-signed, the CLI stops the upgrade unless you specify the full certificate path.
		• Set `verification_mode` to `NONE`.
		`"verification_mode": "NONE"`
		• Specify the full path to the server certificate placed on the client machine that is running on Windows, Linux, or Mac with the following option:
		`"certificate_path": "C:\\server_cert.pem"`
		If you are connecting to a server with a self-signed certificate, and fail to enter the full certificate path, the CLI displays the server's self-signed certificate , and prompts you to accept or reject the certificate.

Table 40: Configuration Parameters in the `new_vcsa` Section, `esxi` Subsection for Deployments without a vSAN and a vSphere Lifecycle Manager Cluster

Name	Type	Description
`hostname`	string	The IP address or FQDN of the target ESX host on which you want to deploy the appliance.
`username`	string	A user name with administrative privileges on the target ESX host, for example, root.
`password`	string	The password of the user with administrative privileges on the target ESX host.

Name	Type	Description
deployment_network	string	The name of the network to which to connect the appliance. **Note:** The network must be accessible from the target ESX host. Ignored if the target ESX host has only one network.
datastore	string	The name of the datastore where you want to store the configuration files and virtual disks of the appliance. **Note:** The datastore must be accessible from the ESX host. If you are using the thin disk mode, the datastore size should have a minimum of 25-GB space.
port	integer	The HTTPS reverse proxy port of the target ESX host. The default port is 443. Use only if the target ESX host uses a custom HTTPS reverse proxy port.
ssl_certificate_verification	string	The CLI verifies that a server's security certificate is signed by a Certificate Authority (CA), and establishes a secure connection. If the certificate is self-signed, the CLI stops the upgrade unless you specify the full certificate path. • Set verification_mode to NONE. "verification_mode": "NONE" • Specify the full path to the server certificate placed on the client machine that is running on Windows, Linux, or Mac with the following option: "certificate_path": "C:\\server_cert.pem" If you are connecting to a server with a self-signed certificate, and fail to enter the full certificate path, the CLI displays the server's self-signed certificate thumbprint, and prompts you to accept or reject the certificate thumbprint.

Table 41: Configuration Parameters in the new_vcsa Section, vc Subsection

Name	Type	Description
hostname	string	The IP address or FQDN of the target vCenter instance on which you want to deploy the appliance.
username	string	vCenter Single Sign-On administrator user name on the target vCenter instance, for example, administrator@vsphere.local.
password	string	The password of the vCenter Single Sign-On administrator user on the target vCenter instance.
deployment_network	string	The name of the network to which to connect the appliance. **Note:** The network must be accessible from the target ESX host or DRS cluster on which you want to deploy the appliance. Ignored if the target ESX host or DRS cluster has only one network.
datacenter	array	The vCenter datacenter that contains the target ESX host or DRS cluster on which you want to deploy the appliance. If the datacenter is located in a folder or a structure of folders, specify the value as a comma-separated list of strings. For example, ["parent_folder", "child_folder", "datacenter_name"] **Note:** The value is case-sensitive.

Name	Type	Description
`datastore`	string	The name of the datastore that you want to store the configuration files and virtual disks of the appliance. **Note:** The datastore must be accessible from the target ESX host or DRS cluster. The datastore must have at least 25 GB of free space.
`port`	integer	The HTTPS reverse proxy port of the target vCenter instance. The default port is 443. Use only if the target vCenter instance uses a custom HTTPS reverse proxy port.

`ssl_certificate_verification`	string	The CLI verifies that a server's security certificate is signed by a Certificate Authority (CA), and establishes a secure connection. If the certificate is self-signed, the CLI stops the upgrade unless you specify the full certificate path.
		• Set `verification_mode` to `NONE`.
		`"verification_mode": "NONE"`
		• Specify the full path to the server certificate placed on the client machine that is running on Windows, Linux, or Mac with the following option:
		`"certificate_path": "C:\\server_cert.pem"`
		If you are connecting to a server with a self-signed certificate, and fail to enter the full certificate path, the CLI displays the server's self-signed certificate thumbprint, and prompts you to accept or reject the certificate thumbprint.

`target`	array	The target ESX host or DRS cluster on which you want to deploy the appliance.
		
		Important:
		You must provide the name that is displayed in the vCenter inventory. For example, if the name of the target ESX host is an IP address in the vCenter inventory, you cannot provide an FQDN.
		If the target ESX host or DRS cluster is located in a folder or a structure of folders, specify the value as a comma-separated list of strings. For example,
		`["parent_folder", "child_folder", "esxi-host.domain.com"]`
		If the target ESX host is part of a cluster, specify the path as a comma-separated list of strings. For example,
		`["cluster_name", "esxi-host.domain.com"]`
		
		Note:
		The value is case-sensitive.

`vm_folder`	string	Optional. The name of the VM folder where the appliance is deployed.

Table 42: Configuration Parameters in the `new_vcsa` Section, `appliance` Subsection

Name	Type	Description
`thin_disk_mode`	Boolean	Set to `true` to deploy the appliance with thin virtual disks.
`deployment_option`	string	The size of the appliance. • Set to `tiny` if you want to deploy a vCenter appliance for up to 10 hosts and 100 virtual machines with the default storage size. Deploys an appliance with 2 CPUs, 12 GB of memory, and 315 GB of storage. • Set to `tiny-lstorage` if you want to deploy a vCenter appliance for up to 10 hosts and 100 virtual machines with the large storage size. Deploys an appliance with 2 CPUs, 12 GB of memory, and 1390 GB of storage. • Set to `tiny-xlstorage` if you want to deploy a vCenter appliance for up to 10 hosts and 100 virtual machines with the x-large storage size. Deploys an appliance with 2 CPUs, 12 GB of memory, and 3145 GB of storage. • Set to `small` if you want to deploy a vCenter appliance for up to 100 hosts and 1,000 virtual machines with the default storage size. Deploys an appliance with 4 CPUs, 19 GB of memory, and 380 GB of storage. • Set to `small-lstorage` if you want to deploy a vCenter appliance for up to 100 hosts and 1,000 virtual machines with the large storage size. Deploys an appliance with 4 CPUs, 19 GB of memory, and 1435 GB of storage. • Set to `small-xlstorage` if you want to deploy a vCenter appliance for up to 100 hosts and 1,000 virtual machines with the x-large storage size. Deploys an appliance with 4 CPUs, 19 GB of memory, and 3195 GB of storage. • Set to `medium` if you want to deploy a vCenter appliance for up to 400 hosts and 4,000 virtual machines with the default storage size. Deploys an appliance with 8 CPUs, 28 GB of memory, and 600 GB of storage. • Set to `medium-lstorage` if you want to deploy a vCenter appliance for up to 400 hosts and 4,000 virtual machines with the large storage size. Deploys an appliance with 8 CPUs, 28 GB of memory, and 1600 GB of storage. • Set to `medium-xlstorage` if you want to deploy a vCenter appliance for up to 400 hosts and 4,000 virtual machines with the x-large storage size. Deploys an appliance with 8 CPUs, 28 GB of memory, and 3360 GB of storage. • Set to `large` if you want to deploy a vCenter appliance for up to 1,000 hosts and 10,000 virtual machines with the default storage size. Deploys an appliance with 16 CPUs, 37 GB of memory, and 965 GB of storage. • Set to `large-lstorage` if you want to deploy a vCenter appliance for up to 1,000 hosts and 10,000 virtual machines with the large storage size. Deploys an appliance with 16 CPUs, 37 GB of memory, and 1665 GB of storage. • Set to `large-xlstorage` if you want to deploy a vCenter appliance for up to 1,000 hosts and 10,000 virtual machines with the x-large storage size. Deploys an appliance with 16 CPUs, 37 GB of memory, and 3425 GB of storage. • Set to `xlarge` if you want to deploy a vCenter appliance for up to 2,000 hosts and 35,000 virtual machines with the default storage size. Deploys an appliance with 24 CPUs, 56 GB of memory, and 1705 GB of storage. • Set to `xlarge-lstorage` if you want to deploy a vCenter appliance for up to 2,000 hosts and 35,000 virtual machines with the large storage size. Deploys an appliance with 24 CPUs, 56 GB of memory, and 1805 GB of storage. • Set to `xlarge-xlstorage` if you want to deploy a vCenter appliance for up to 2,000 hosts and 35,000 virtual machines with the x-large storage size. Deploys an appliance with 24 CPUs, 56 GB of memory, and 3565 GB of storage.
`image`	string	Optional. A local file path or URL to the vCenter appliance installation package. By default the installer uses the installation package that is included in the ISO file, in the `vcsa` folder.
`name`	string	The VM name for the appliance. Must contain only ASCII characters except a percent sign (%), backslash (\), or forward slash (/) and must be no more than 80 characters in length.

Name	Type	Description
ovftool_path	string	Optional. A local file path to the OVF Tool executable file. By default the installer uses the OVF Tool instance that is included in the ISO file, in the vcsa/ovftool folder.

Table 43: Configuration Parameters in the new_vcsa Section, install_parameters Subsection

Name	Type	Description
mac_allocation_prefix	string	The MAC prefix if a prefix-based MAC allocation scheme is used for the VM managed by the appliance.
mac_allocation_prefix_length	integer	The MAC prefix length if a prefix-based MAC allocation scheme is used for the VM managed by the appliance.

Table 44: Configuration Parameters in the new_vcsa Section, network Subsection

Name	Type	Description
ip_family	string	IP version for the network of the appliance. Set to ipv4 or ipv6.
mode	string	IP assignment for the network of the appliance. Set to static or dhcp.
system_name	string	Primary network identity. Can be an IP address or FQDN, preferably FQDN. It is used only when the mode parameter is set to static. You cannot change the value of this parameter after the deployment. The FQDN and dotted-decimal numbers must comply with the RFC 1123 guidelines. Mandatory if you provide network configuration settings in the v4 and/or v6 subsections and the mode parameter is set to static.
ip	string	IP address for the appliance. Required only if you use static assignment, that is, if you set the mode parameter to static. You must set an IPv4 or IPv6 address that corresponds to the network IP version, that is, to the value of the ip.family parameter. An IPv4 address must comply with the RFC 790 guidelines. An IPv6 address must comply with the RFC 2373 guidelines.
prefix	string	Network prefix length. Use only if the mode parameter is set to static. Remove if the mode parameter is set to dhcp. The network prefix length is the number of bits that are set in the subnet mask. For example, if the subnet mask is 255.255.255.0, there are 24 bits in the binary version of the prefix length, so the network prefix length is 24. For IPv4 version, the value must be between 0 and 32. For IPv6 version, the value must be between 0 and 128.
gateway	string	IP address of the default gateway. For IPv6 version, the value can be default.

Name	Type	Description

dns_servers	string or array	IP addresses of one or more DNS servers.
		To set more than one DNS server, use a comma-separated list of strings or a comma-separated list as a single string to provide the path. For example,
		`["x.y.z.a", "x.y.z.b"]`
		or
		`"x.y.z.a, x.y.z.b"`
		Optional when the mode parameter is set to static. Not supported when mode is set to DHCP.
		Mandatory if you provide network configuration settings in the v4 and/or v6 subsections and the mode parameter is set to static.

ports	string	Optional. Port numbers that the vCenter appliance uses for direct HTTP connections. By default, port 80 redirects requests to HTTPS port 443. You can customize the vCenter HTTP and HTTPS ports. If specifying a custom HTTP and HTTPS port number, ensure that you do not use a port already in use by vCenter, or the default HTTP and HTTPS ports of 80 and 443. The options to specify a custom port are: "rhttpproxy.ext.port1":"*port_number*" for the HTTP port, and "rhttpproxy.ext.port2:"*port_number*" for the HTTPS port. The following example specifies ports 81 and 444 for the HTTP and HTTPS ports: `ports: {"rhttpproxy.ext.port1":"81", "rhttpproxy.ext.port2":"444"}` For more information on ports in use by vCenter , see Required Ports for vCenter .
v4	string	Network configuration settings for IPv4 for dual IP stack. To use more than one network, dual IP stack (IPv4 and IPv6), with vCenter 9.1 you can set the v4 and v6 parameters in your JSON template. During vCenter firstboot, both IPv4 and IPv6 network configurations are applied. If the hostname parameter in the esxi subsection is an IPv4 address, the primary network is IPv4 and the secondary is IPv6.
v6	string	Network configuration settings for IPv6 for dual IP stack. To use more than one network, dual IP stack (IPv4 and IPv6), with vCenter 9.1 you can set the v4 and v6 parameters in your JSON template. During vCenter firstboot, both IPv4 and IPv6 network configurations are applied. If the hostname parameter in the esxi subsection is an IPv6 address, the primary network is IPv6 and the secondary is IPv4.

Table 45: Configuration Parameters in the `v4` and `v6` Subsections, `network` Subsection

Name	Type	Description
mode	string	IP assignment for the network of the appliance. Set to static or dhcp.
prefix	string	Network prefix length. Use only if the mode parameter is set to static. Remove if the mode parameter is set to dhcp. The network prefix length is the number of bits that are set in the subnet mask. For example, if the subnet mask is 255.255.255.0, there are 24 bits in the binary version of the prefix length, so the network prefix length is 24. For IPv4 version, the value must be between 0 and 32. For IPv6 version, the value must be between 0 and 128.
ip	string	IP address for the appliance. Required only if you use static assignment, that is, if you set the mode parameter to static. You must set an IPv4 or IPv6 address that corresponds to the network IP version, that is, to the value of the ip.family parameter. An IPv4 address must comply with the RFC 790 guidelines. An IPv6 address must comply with the RFC 2373 guidelines.

Name	Type	Description
gateway	string	IP address of the default gateway. For IPv6 version, the value can be `default`.

Table 46: Configuration Parameters in the `new_vcsa` Section, `os` Subsection

Name	Type	Description
password	string	The password for the root user of the appliance operating system. The password must contain between 8 and 20 characters, at least one uppercase letter, at least one lowercase letter, at least one number, and at least one special character, for example, a dollar sign ($), hash key (#), at sign (@), period (.), or exclamation mark (!). All characters must be lower ASCII characters without spaces.

ntp_servers	string or array	Optional. Host names or IP addresses of one or more NTP servers for time synchronization.
		To set more than one NTP server, use a comma-separated list of strings or a comma-separated list as a single string to provide the path. For example,
		`["x.y.z.a", "x.y.z.b"]`
		or
		`"x.y.z.a, x.y.z.b"`

ssh_enable	Boolean	Set to `true` to enable SSH administrator login to the appliance. **Note:** vCenter appliance high availability requires remote SSH access to the appliance.
time_tools_sync	Boolean	Optional. Set to `true` to deploy the appliance with the VMware Tools time synchronization. VMware Tools synchronizes the time of the appliance with the time of the ESX host. Ignored if you set NTP servers for time synchronization, that is, if you set the `ntp.servers` parameter.

Table 47: Configuration Parameters in the `new_vcsa` Section, `sso` Subsection

Name	Type	Description
password	string	Password of the vCenter Single Sign-On administrator user, administrator@*`your_domain_name`*. If you are deploying a vCenter appliance as the first instance in a new vCenter Single Sign-On domain, you must set the password for thevCenter Single Sign-On administrator user. The password must contain between 8 and 20 characters, at least one uppercase letter, at least one lowercase letter, at least one number, and at least one special character, for example, a dollar sign ($), hash key (#), at sign (@), period (.), or exclamation mark (!). All characters must be ASCII characters.
domain_name	string	vCenter Single Sign-On domain name, for example, vsphere.local. If you are deploying a vCenter appliance as the first instance in a new vCenter Single Sign-On domain, you must set the name for the new vCenter Single Sign-On domain.
replication_partner_hostname	string	The system name of the partner vCenter. Required only if you are deploying a replication partner in an existing vCenter Single Sign-On domain.
first_instance	string	Set `first_instance` to `true` if you do not want to set the replication partner for this node. If you want to set the replication partner for this node, set `first_instance` to `false` and provide the value of the `replication_partner_hostname` as the FQDN of a previously converged node which is currently in an embedded vCenter topology.

Name	Type	Description
sso_port	integer	The HTTPS reverse proxy port of the partner vCenter . The default port is 443. Use only if the partner uses a custom HTTPS reverse proxy port.

Configuration Parameters in the ceip Section

Table 48: Configuration Parameters in the ceip Section, settings Subsection

Name	Type	Description
ceip_enabled	Boolean	Set to true to join the CEIP for this appliance.

Syntax of the CLI Deployment Command

You can use command arguments to set the execution parameters of the deployment command.

You can add a space-separated list of arguments to the CLI deployment command.

```
vcsa-deploy install path_to_the_json_filelist_of_arguments
```

Argument	Description
--accept-eula	Accepts the end-user license agreement. Required for executing the deployment command.
--acknowledge-ceip	Confirms your acknowledgement of your VMware Customer Experience Improvement Program (CEIP) participation. Required if the ceip.enabled parameter is set to true in the JSON deployment template.
-v, --verbose	Adds debug information to the console output.
-t, --terse	Hides the console output. Displays only warning and error messages.
--log-dir*LOG_DIR*	Sets the location of the log and other output files.
--skip-ovftool-verification	Performs basic verification of the configuration parameters in the JSON file and deploys the appliance. Does not perform verification of the OVF Tool parameters.
--no-esx-ssl-verify	Skips the SSL verification for ESX connections. **Important:** Avoid using this option because it might cause problems during deployment or after deployment because of not validated identity of the target ESX host.
--no-ssl-certificate-verification	Skips security certificate verification for all server connections.
--operation-id*OPERATION_ID*	Provides an operation ID to track installation activities.
--pause-on-warnings	Pauses and waits for acknowledgment of warnings.
--verify-template-only	Performs basic template verification of the configuration parameters in the JSON file. Does not deploy the appliance.
--precheck-only	Performs only the basic template verification and OVF Tool parameter verification. Does not deploy the appliance.
-h, --help	Displays the help message for the vcsa-deploy install command.
--template-help	Displays the help message for the use of configuration parameters in the JSON deployment file.

Argument	Description
`--provide-passwd-in-stdin`	Allows you to send passwords through standard input to the CLI installer. Passwords provided through standard input are given precedence over the passwords provided through a JSON template. Passwords can be send to the CLI Installer in the following way: `echo '{"section1.subsection1.passwordkey1": "password1", "section2.subsection2.passwordkey2": "password2"}' | vcsa-deploy install <template.json> <arguments> --provide-passwd-in-stdin` The argument can be used for deployment and upgrade operations.

After the execution finishes, you can get the exit code of the command.

Exit Code	Description
0	Command ran successfully
1	Runtime error
2	Validation error
3	Template error

Deploy a vCenter Appliance by Using the CLI

You can use the CLI installer to perform an unattended deployment of a vCenter appliance. You must run the CLI deployment from a Windows, Linux, or Mac machine that is in the network on which you want to deploy the appliance.

- See Prerequisites for Deploying the vCenter Appliance.
- Prepare Your JSON Configuration File for CLI Deployment.
- Review Syntax of the CLI Deployment Command.
- Verify that the user name with which you are logged in to your client machine, the path to the vCenter installer, the path to your JSON configuration file, and the string values in your JSON configuration file contain only ASCII characters. Extended ASCII and non-ASCII characters are unsupported.

1. Navigate to the `vcsa-cli-installer` subdirectory for your operating system.
   - If you are running the deployment on Windows OS, navigate to the `vcsa-cli-installer\win32` directory.
   - If you are running the deployment on Linux OS, navigate to the `vcsa-cli-installer/lin64` directory.
   - If you are running the deployment on Mac OS, navigate to the `vcsa-cli-installer/mac` directory.
2. Optional: Run a pre-deployment check without deploying the appliance to verify that you prepared the deployment template correctly.

   ```
   vcsa-deploy install --accept-eula --precheck-only path_to_the_json_file
   ```

3. Run the deployment command.

   ```
   vcsa-deploy install --accept-eula --acknowledge-ceip optional_argumentspath_to_the_json_file
   ```

   Use *optional_arguments* to enter space-separated arguments to set additional execution parameters of the deployment command.

   For example, you can set the location of the log and other output files that the installer generates.

   ```
   vcsa-deploy install --accept-eula --acknowledge-ceip --log-dir=path_to_the_locationpath_to_the_json_file
   ```

Deploy Multiple vCenter Appliances Using the CLI

You can deploy multiple instances vCenter appliances concurrently (in batch mode) using the CLI installer.

To deploy multiple instances concurrently, create JSON templates for all the vCenter instances in your deployment. The CLI installer assesses the topology of the deployment using the JSON templates, and determines the order. For this reason, the JSON templates must use static IP addresses for all vCenter instances in the deployment that are dependant upon one another.

> **Important:**
> The JSON templates that you create for each appliance must use a static IP address to resolve the network addresses of other appliances in the deployment upon which they have a dependency.

To perform the batch deployment, place the JSON templates defining your deployment in a single directory. When invoked, the CLI installer deploys your existing deployment using the topology that is defined in the JSON templates.

1. In your workspace, create a folder to contain the JSON files for batch deployment. For example, *`MyWorkspace/BatchDeploy`*.
2. Prepare each JSON configuration file and copy the file to your batch deployment folder. See Prepare Your JSON Configuration File for CLI Deployment for instructions on configuring the JSON files.
3. Navigate to the `vcsa-cli-installer` subdirectory for your operating system.
   - If you are running the deployment on Windows OS, navigate to the `vcsa-cli-installer\win32` directory.
   - If you are running the deployment on Linux OS, navigate to the `vcsa-cli-installer/lin64` directory.
   - If you are running the deployment on Mac OS, navigate to the `vcsa-cli-installer/mac` directory.
4. Optional: Run a pre-deployment check without deploying the appliance to verify that you prepared the deployment template correctly. For example:

   ```
   vcsa-deploy install --precheck-only MyWorkspace/BatchDeploy
   ```

5. Run the deployment command. For example,

   ```
   vcsa-deploy install --accept-eula --acknowledge-ceip optional_argumentsMyWorkspace/BatchDeploy
   ```

   Use *`optional_arguments`* to enter space-separated arguments to set additional execution parameters of the deployment command.

   For example, you can set the location of the log and other output files that the installer generates.

   ```
   vcsa-deploy install --accept-eula --acknowledge-ceip --log-dir=path_to_the_locationMyWorkspace/BatchDeploy
   ```

File-Based Backup and Restore of vCenter

vCenter supports a file-based backup and restore mechanism that helps you to recover your environment after failures.

You can use the vCenter Management Interface to create a file-based backup of the vCenter. After you create the backup, you can restore it by using the GUI installer of the appliance.

You use the vCenter Management Interface to perform a file-based backup of the vCenter core configuration, inventory, and historical data of your choice. The backed-up data is streamed over FTP, FTPS, HTTP, HTTPS, SFTP, NFS, or SMB to a remote system. The backup is not stored on the vCenter.

You can perform a file-based restore only for a vCenter that you have previously backed up by using the vCenter Management Interface. You can perform such restore operation by using the GUI installer of the vCenter appliance. The process consists of deploying a new vCenter appliance and copying the data from the file-based backup to the new appliance.

> **Important:**
> If you back up a vCenter High Availability cluster, the backup operation only backs up the primary vCenter instance. Before restoring a vCenter High Availability cluster, you must power off the active, passive, and witness nodes. The restore operation restores the vCenter in non- vCenter High Availability mode. You must reconstruct the cluster after the restore operation completes successfully.

Considerations and Limitations for File-Based Backup and Restore

When you back up or restore a vCenter instance, consider these considerations and limitations.

Protocols

The following considerations apply to file-based backup and restore protocols:

- FTP and HTTP are not secure protocols.
- Backup servers must support minimum of 10 simultaneous connections for each vCenter.
- You can use an FTP, FTPS, HTTP, HTTPS, SFTP, NFS, or SMB server that is up and running with sufficient disk space to store the backup.
- You must have a complete backup location path created with write and read permissions.
- Only explicit mode is supported for FTPS.
- If you use HTTP or HTTPS, you must enable WebDAV on the backup web server.
- You can use only FTP, FTPS, HTTP, or HTTPS to transmit data through an HTTP proxy server.
- You can use IPv4 and IPv6 URLs in file-based backup and can restore of a vCenter. Mixed mode of IP versions between the backup server and the vCenter is unsupported.

Configuration

After a restore, the following configurations revert to the state when the backup was taken.

- Virtual machine resource settings
- Resource pool hierarchy and setting
- Cluster-host membership
- DRS configuration and rules

Storage DRS

If the configuration changes, the following might change after a restore.

- Datastore Cluster configuration
- Datastore Cluster membership
- Datastore I/O Resource Management (Storage I/O Control) settings
- Datastore-Datacenter membership
- Host-Datastore membership

Distributed Power Management

If you put an ESX host into standby mode after a backup, the vCenter might force the host to exit standby mode when you restore to the backup.

Distributed Virtual Switch

If you use a distributed virtual switch, you are advised to export separately the distributed virtual switch configuration before you restore from a backup. You can import the configuration after the restore. If you omit this consideration, you may lose the changes made to a distributed virtual switch after the backup. For detailed steps, see the Broadcom knowledge base article 338595.

However, when you restore the host-membership after a backup, you will not lose any host that you have added or removed from the distributed virtual switch after the backup.

Note:
You can only restore the distributed virtual switch-host membership if the host is part of the cluster.

Content Libraries

If you delete libraries or items after a backup, you cannot access or use these libraries or items after the restore. You can only delete such libraries or items. A warning message notifies you that there are missing files or folders in the storage backup.

If you create new items or item files after the backup, the Content Library Service has no record of the new items or files after the restore operation. A warning notifies you that extra folders or files were found on the storage backup.

If you create new libraries after the backup, the Content Library Service has no record of the new libraries after restore. The library content exists on the storage backing, but no warning is displayed. You must manually clean the new libraries.

Virtual Machine Life Cycle Operations

- Restoring vCenter from a backup that was taken during in-flight relocation operations in the vCenter instance.
  After you restore vCenter, the vCenter view of the virtual machines might be out of sync with the ESX view of the virtual machines. This is also true if you performed the backup during in-flight operations on vCenter. If virtual machines disappear after you restore vCenter, you can refer to the following cases.
  a. The missing virtual machine is located on the destination ESX host and is registered with the destination ESX host, but it is either an orphan or not in the vCenter inventory. You must manually add the virtual machine to the vCenter inventory.
  b. The missing virtual machine is located on the destination ESX host, but it is not registered with the destination ESX host and it is not in the vCenter inventory. You must manually register the virtual machine to the ESX host and add the virtual machine back to the vCenter inventory.
  c. The missing virtual machine is located on the destination ESX host, but it is not registered with the destination ESX host. In the vCenter instance, the missing virtual machine is marked as orphaned. You must remove the virtual machine from the vCenter inventory and add it again.
- Restoring vCenter from a backup that has an out-of-date linked clone virtual machine layout.
  If you create a linked clone virtual machine after the backup and you restore vCenter from the old backup, then after the restore, the vCenter does not know about the new linked clone virtual machine until vCenter discovers the new linked clone virtual machine. If you remove all existing virtual machines before the new linked clone virtual machine is discovered, then the removal of existing virtual machines corrupts the new linked clone due to missing disks. To avoid this, you must wait until all linked clone virtual machines are discovered by the vCenter before you remove virtual machines.
- Restoring vCenter from a backup that was taken during virtual machine registration.
  If you are registering a virtual machine during the backup and you restore vCenter from the old backup, then after the restore, the virtual machine is marked as orphaned in the vCenter instance. You must manually add the virtual machine to the vCenter inventory.

vCenter Enhanced Linked Mode

To restore a vCenter instance that is part of an Enhanced Linked Mode, you must have at least one running vCenter that has the VMware Directory Service database.

If the replication partners are temporarily unavailable or network-isolated, fix the replication partners before restoring the node. If all nodes in the federation have failed, you can ignore the warning and restore only the first node without replication partners. Restore the rest of the nodes according to the Enhanced Linked Mode topology.

vSphere High Availability

Restoring vCenter from a backup might cause it to rollback to older version for the vSphere HA cluster state (HostList, ClusterConfiguration, VM protection state) while the hosts in the cluster have the latest version for the cluster state. You need to make sure the vSphere HA cluster state stays the same during restore and backup operations. Otherwise, the following problems might occur.

- If hosts are added or removed to or from the vSphere HA cluster after backup and before vCenter restore, virtual machines could potentially failover to hosts not being managed by the vCenter but are still part of the HA cluster.

- Protection state for new virtual machines is not updated on the vSphere HA agents on the hosts that are part of the vSphere HA cluster. As a result, virtual machines are not protected or unprotected.
- New cluster configuration state is not updated on the vSphere HA agents on the hosts that are part of the vSphere HA cluster.

vCenter High Availability

Restoring vCenter requires vCenter HA to be reconfigured.

Storage Policy Based Management

Restoring vCenter from a backup can lead to the following inconsistencies related to storage policies, storage providers, and virtual machines.

- Registered storage providers after backup are lost.
- Unregistered storage providers after backup re-appear and might show a different provider status.
- Changes, such as create, delete, or update, performed on storage policies after backup are lost.
- Changes, such as create, delete, or update, performed on storage policy components after backup are lost.
- Default policy configuration changes for datastores performed after backup are lost.
- Changes in the storage policy association of the virtual machine and its disks, and in their policy compliance might occur.

Virtual Storage Area Network

Restoring vCenter from a backup might cause inconsistencies in the vSAN. For information on how to check vSAN health, see *Administering VMware vSAN*.

Patching

Restoring vCenter from a backup might result in missing security patches. You must apply them again after the restore is complete. For information on patching the vCenter, see Patching vCenter in *vSphere Upgrade*.

Schedule a File-Based Backup

You can schedule file-based backups for vSphere 8.0 and later. You can set up a schedule that is used to perform periodic backups.

- You must have an FTP, FTPS, HTTP, HTTPS, SFTP, NFS, or SMB server up and running with sufficient disk space to store the backup.

The schedule can be set up with information about the backup location, recurrence, and retention for the backups.

You can only set up one schedule at a time.

1. In a web browser, go to the vCenter Management Interface, https://`appliance-IP-address-or-FQDN`:5480.
2. Log in as root.
3. In the vCenter Management Interface, click **Backup**.
4. Click **Configure** to set up a backup schedule.
5. Enter the backup location details.

Option	Description
Backup location	Enter the backup location, including the protocol to use to connect to your backup server, the port, the server address, and the backup folder to store the backup files. Use one of the following protocols: FTP, FTPS, HTTP, HTTPS, SFTP, NFS, or SMB. For FTP, FTPS, HTTP, or HTTPS the path is relative to the home directory configured for the service.

Option	Description
Backup server credentials	Enter a user name and password of a user with**write** privileges on the backup server.

6. Set the schedule recurrence and time for the backup.

   The recurrence can be set daily, weekly, or you can customize the schedule to run the backup on a specific day or days of the week. You can specify the time of day to run the backup. The default time is 11:59pm.

7. Optional: Enter an Encryption Password if you want to encrypt your backup file.

   If you select to encrypt the backup data, you must use the encryption password for the restore procedure.

8. Select **Retain all backups** or enter the number of backups to retain.

   The retention information provides the number of backups to retain for a given vCenter.

   Note:
   This policy applies to both manual and scheduled backups.

9. Optional: Select **Stats, Events, and Tasks** to back up additional historical data from the database.

10. Optional: Select **Supervisors Control Plane** to activate the backup and restore of a Supervisor in the case of any disaster scenario. This allows you to record the state of the Supervisors Control Planes in a vCenter system.

    For more information, see Backing Up and Restoring vSphere Supervisor.

11. Click **Create**.

    The backup schedule information is populated in the Backup page.

The complete and in progress backups are listed under Activity.
You can perform an immediate backup with the existing schedule information by selecting **Use backup location and user name from backup schedule** from the backup schedule on the Backup Now dialog box.

Manually Back Up vCenter by Using the vCenter Management Interface

You can use the vCenter Management Interface to back up the vCenter instance. You can select whether to include historical data, such as stats, events, and tasks, in the backup file.

- You must have and FTP, FTPS, HTTP, HTTPS, SFTP, NFS, or SMB server up and running with sufficient disk space to store the backup.

  Note:

  The backup operation for a vCenter High Availability cluster, backs up only the active node.

1. In a web browser, go to the vCenter Management Interface, https://*vcenter-IP-address-or-FQDN*:5480.
2. Log in as root.
3. In the vCenter Management Interface, click **Backup**.

   The table under **Activity** displays the most current backup version that is taken of the vCenter.

4. Click **Back up now**.

   The **Back up Now** wizard opens.

5. Optional: Select **Use backup location and user name from backup schedule** to use the information from a scheduled backup.
6. Enter the backup location details.

Option	Description
Backup location	Enter the backup location, including the protocol to use to connect to your backup server, the port, the server address, and the backup folder to store the backup files. Use one of the following protocols: FTP, FTPS, HTTP, HTTPS, SFTP, NFS, or SMB.

Option	Description
	For FTP, FTPS, HTTP, or HTTPS the path is relative to the home directory configured for the service.
Backup server credentials	Enter a user name and password of a user with **write** privileges on the backup server. **Note:** Username and password should only contain ASCII characters.

7. Optional: Enter an Encryption Password if you want to encrypt your backup file.
   If you select to encrypt the backup data, you must use the encryption password for the restore procedure.
8. Optional: Select **Stats, Events, and Tasks** to back up additional historical data from the database.
9. Optional: In the **Description** text box, enter a description of the backup.
10. Click **Start** to begin the backup process.

The complete and in progress backups are listed under Activity.

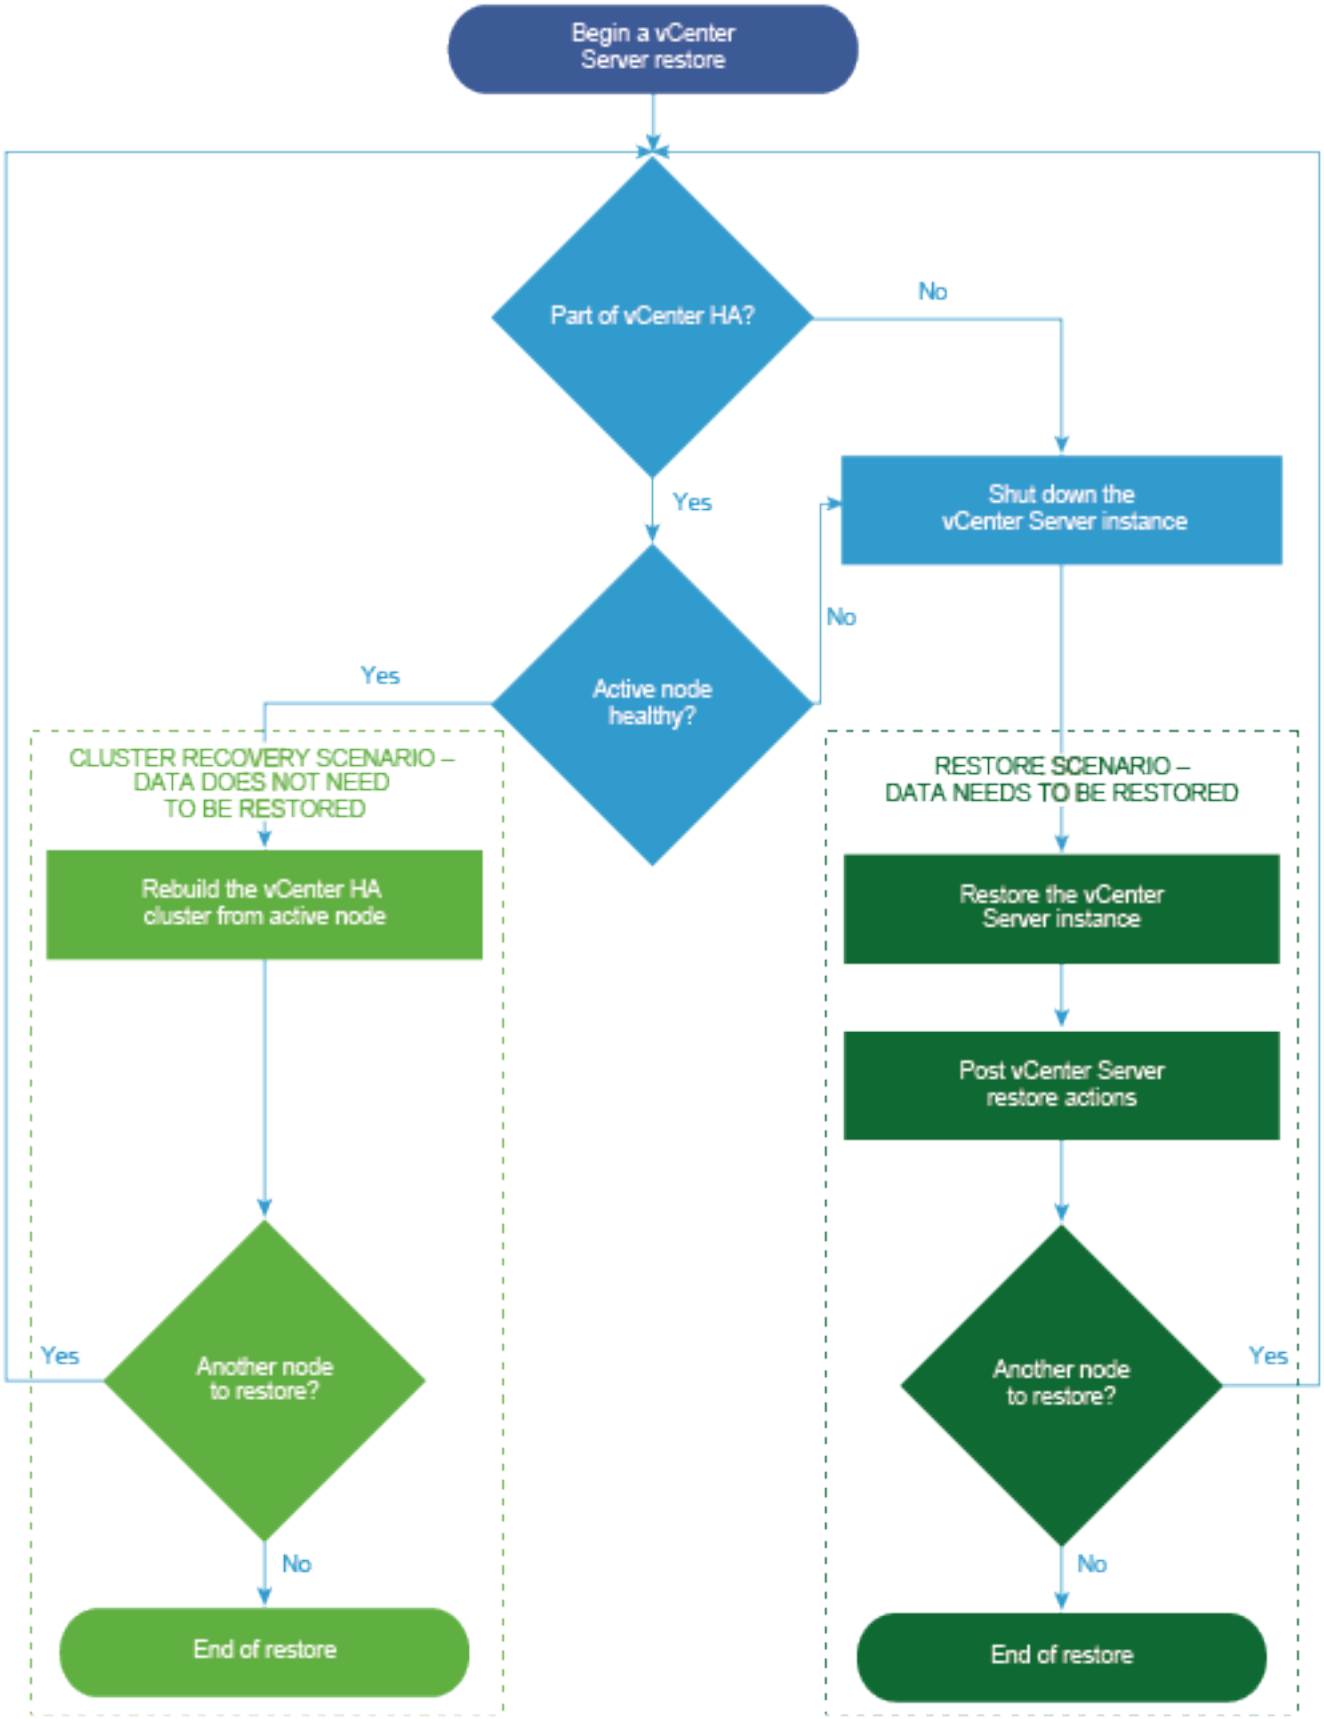
Restore vCenter from a File-Based Backup

You can use the vCenter appliance GUI installer to restore a vCenter to an ESX host or a vCenter instance. The restore procedure has two stages. The first stage deploys a new vCenter appliance. The second stage populates the newly deployed vCenter appliance with the data that is stored in the file-based backup.

- Verify that your system meets the minimum software and hardware requirements. See System Requirements for the vCenter Appliance.

- If the vCenter instance is part of a vCenter High Availability cluster, you must power off the active, passive, and witness nodes of the cluster before restoring the vCenter.

Figure 17: vCenter Restore Workflow



Stage 1 - Deploy a New Appliance

In stage 1 of the restore process, you deploy the OVA file, which is included in the vCenter GUI installer.

- Download and mount the vCenter installer. See Download and Mount the vCenter Installer.

  Note:

  If you are restoring a backup from a product that has a vCenter product patch applied, you must download the full ISO of that particular patch.
- If you plan to restore the vCenter on an ESX host, verify that the target ESX host is not in lockdown or maintenance mode or part of a fully automated DRS cluster.
- If you plan to restore the vCenter on a DRS cluster of a vCenter inventory, verify that the cluster contains at least one ESX host that is not in lockdown or maintenance mode.
- If you plan to assign a static IP address to the appliance, verify that you have configured the forward and reverse DNS records for the IP address.
- If you are attempting to restore a vCenter instance that is still running, power off the backed-up vCenter before you start the restore operation.

As an alternative to performing the first stage of the restore with the GUI installer, you can deploy the OVA file of the new vCenter appliance by using the vSphere Client. After the OVA deployment, you must log in to the vCenter Management Interface of the newly deployed appliance to proceed with the second stage of the restore process. See "Deploy an OVF or OVA Template" in *vSphere Virtual Machine Administration* vSphere Virtual Machine Administration for information about deploying an OVA file using the vSphere Client.

1. In the vCenter installer, navigate to the `vcsa-ui-installer` directory, go to the subdirectory for your operating system, and run the installer executable file.
   - For Windows OS, go to the `win32` subdirectory, and run the `installer.exe` file.
   - For Linux OS, go to the `lin64` subdirectory, and run the `installer` file.
   - For Mac OS, go to the `mac` subdirectory, and run the `Installer.app` file.
2. On the Home page, click **Restore**.
3. Review the Introduction page to understand the restore process and click **Next**.
4. Read and accept the license agreement, and click **Next**.
5. On the Enter backup details page, enter the details of the backup file that you want to restore, and click **Next**.

Option	Description
Backup location	Enter the server address and backup folder where the backup files are stored. You can also enter the IP address or hostname of the backup server and browse for the location of the backup folder. Specify the protocol to use to retrieve the backup from your backup server. You can select FTP, FTPS, HTTP, HTTPS, SFTP, NFS, or SMB. For example, `ftp://<server_IP_address>/tmp/vCenter/hostname_vcenter.com/<backup_filename>`
User name	Enter the user name of a user with **read** privileges on the backup server.
Password	Enter the password of the user with **read** privileges on the backup server.

6. Review the backup information, and click **Next**.
7. Connect to the ESX host or vCenter on which you want to deploy the vCenter appliance to use for the restore operation.

Option	Steps
You can connect to an ESX host on which to deploy the appliance to use for the restore operation.	1. Enter the FQDN or IP address of the ESX host. 2. Enter the HTTPS port of the ESX host. 3. Enter the user name and password of a user with administrative privileges on the ESX host, for example, the root user. 4. Click **Next**. 5. Verify that the certificate warning displays the SHA1 thumbprint of the SSL certificate that is installed on the target ESX host, and click **Yes** to accept the certificate thumbprint.
You can connect to a vCenter instance and browse the inventory to select an ESX host or DRS cluster on which to deploy the appliance to use for the restore operation.	1. Enter the FQDN or IP address of the vCenter instance. 2. Enter the HTTPS port of the vCenter instance. 3. Enter the user name and password of user with vCenter Single Sign-On administrative privileges on the vCenter instance, for example, the administrator@*your_domain_name* user. 4. Click **Next**. 5. Verify that the certificate warning displays the SHA1 thumbprint of the SSL certificate that is installed on the target vCenter instance, and click **Yes** to accept the certificate thumbprint. 6. Select the data center or data center folder that contains the ESX host or DRS cluster on which you want to deploy the appliance, and click **Next**. **Note:** You must select a data center or data center folder that contains at least one ESX host that is not in lockdown or maintenance mode. 7. Select the ESX host or DRS cluster on which you want to deploy the appliance, and click **Next**.

8. Accept the certificate warning.
9. Enter a name for the vCenter appliance, set up the password for the root user, and click **Next**.
10. Select the deployment size for the new vCenter appliance depending on the size of your vSphere inventory.

Deployment Profile	Description
Tiny	Deploys an appliance with 2 vCPUs and 14 GB of memory. Suitable for environments with up to 10 hosts or 100 virtual machines
Small	Deploys an appliance with 4 vCPUs and 21 GB of memory. Suitable for environments with up to 100 hosts or 1,000 virtual machines
Medium	Deploys an appliance with 8 vCPUs and 30 GB of memory. Suitable for environments with up to 400 hosts or 4,000 virtual machines
Large	Deploys an appliance with 16 vCPUs and 39 GB of memory. Suitable for environments with up to 1,000 hosts or 10,000 virtual machines
X-Large	Deploys an appliance with 24 vCPUs and 58 GB of memory.

Deployment Profile	Description
	Suitable for environments with up to 2,500 hosts or 30,000 virtual machines. Suitable for environments with up to 2,500 hosts or 45,000 virtual machines with X-Large Storage.

11. Select the storage size for the new vCenter appliance, and click **Next**.

    Important:
    You must consider the storage size of the appliance that you are restoring.

Storage Size Option	Tiny	Small	Medium	Large	X-Large
Default	Deploys an appliance with 619 GB of storage.	Deploys an appliance with 734 GB of storage.	Deploys an appliance with 933 GB of storage.	Deploys an appliance with 1383 GB of storage.	Deploys an appliance with 2308 GB of storage.
Large	Deploys an appliance with 2059 GB of storage.	Deploys an appliance with 2084 GB of storage.	Deploys an appliance with 2233 GB of storage.	Deploys an appliance with 2283 GB of storage.	Deploys an appliance with 2408 GB of storage.
X-Large	Deploys an appliance with 4319 GB of storage.	Deploys an appliance with 4344 GB of storage.	Deploys an appliance with 4493 GB of storage.	Deploys an appliance with 4543 GB of storage.	Deploys an appliance with 4668 GB of storage.

12. From the list of available datastores, select the location where all the virtual machine configuration files and virtual disks will be stored and, optionally, enable thin provisioning by selecting **Enable Thin Disk Mode**.
13. On the Configure network settings page review the settings populated from the backup file of the vCenter.
14. Optional: Edit the network configuration to match the current network environment where the vCenter is restored.
15. On the Ready to complete stage 1 page, review the deployment settings for the restored vCenter appliance and click **Finish** to start the OVA deployment process.
16. Wait for the OVA deployment to finish, and click **Continue** to proceed with stage 2 of the restore process to transfer the data to the newly deployed appliance.

    Note:
    If you exit the wizard by clicking **Close**, you must log in to the vCenter Management Interface to transfer the data.

The newly deployed vCenter appliance is running on the target server but the data is not copied from the backup location.

Stage 2 - Transfer Data to the Newly Deployed Appliance

After the OVA deployment finishes, you are redirected to stage 2 of the restore process in which the data from the backup location is copied to the newly deployed vCenter appliance.

1. Review the introduction to stage 2 of the restore process and click **Next**.
2. Review the backup details and click **Next**.
3. If you are restoring a node with enhanced linked mode support for vCenter appliance, you are asked to provide the Single Sign-On credentials. Enter the Single Sign-On user name and password, then click **Validate and Recover**.
4. On the Ready to complete page, review the details, click **Finish**, and click **OK** to complete stage 2 of the restore process.

   The restore process restarts the vCenter Management Service. You cannot access the vCenter Management API during the restart.

   Important:
   If a restore operation of a vCenter appliance VM results with a failure, you must power off and delete the partially restored VM. After that you can try to restore the VM again.

5. Optional: After the restore process finishes, click the **https://*vcenter_IP_or_fqdn*/ui** to go to the vSphere Client and log in to the vCenter instance , or click the **https://*vcenter_IP_or_fqdn*:443** to go to the vCenter Getting Started page.
6. Click **Close** to exit the wizard.

   You are redirected to the vCenter Getting Started page.
7. If the backed up vCenter node is part of a vCenter High Availability cluster, the last needs to be reconfigured after the restore operation completes successfully.

   For information about how to perform backup and restore operations, see *vSphere Availability*.

After successful completion of the restore operation, in the event of a total loss of all storage and servers where all the physical hardware or the data in the hardware is lost, follow the instructions in the Broadcom knowledge base article 332503 in order to recover the system to a pre-restore state at the time of the backup.

Image-Based Backup and Restore of a vCenter Environment

You can use vSphere APIs with a third-party product to back up and restore a virtual machine that contains vCenter.

You can perform a full image backup of a virtual machine that contains vCenter. The virtual machine must use a fully qualified domain name (FQDN) with correct DNS resolution, or the hostname must be configured to be an IP address.

Considerations and Limitations for Image-Based Backup and Restore

When you restore a vCenter environment, take into account these considerations and limitations.

> **Note:**
> Restoring a vCenter instance with DHCP network configuration results in changing its IP address. The changed IP address prevents some vCenter services from starting properly. To start all vCenter services successfully, after the restore, you must reconfigure the IP address of the restored vCenter instance to the IP address that the instance was set to when you performed the backup.

Synchronizing Clocks with NTP Time Synchronization Prior to Backup

Before creating a backup of your vCenter deployment, verify that all components on the vSphere network have their clocks synchronized using NTP time synchronization. See Synchronizing Clocks on the vSphere Network.

Configuration

After a restore, the following configurations revert to the state when the backup was taken.

- Virtual machine resource settings
- Resource pool hierarchy and setting
- Cluster-host membership
- DRS configuration and rules

Storage DRS

If the configuration changes, the following might change after a restore.

- Datastore Cluster configuration
- Datastore Cluster membership
- Datastore I/O Resource Management (Storage I/O Control) settings
- Datastore-Datacenter membership
- Host-Datastore membership

Distributed Power Management

If you put a host into standby mode after a backup, the vCenter might force the host to exit standby mode when you restore to the backup.

Distributed Virtual Switch

If you use a distributed virtual switch, you are advised to export separately the distributed virtual switch configuration before you restore to a backup. You can import the configuration after the restore. If you omit this consideration, you may lose the changes made to a distributed virtual switch after the backup. For detailed steps, see the Broadcom knowledge base article 338595.

Content Libraries

If you delete libraries or items after a backup, you cannot access or use these libraries or items after the restore. You can only delete such libraries or items. A warning message notifies you that there are missing files or folders in the storage backup.

If you create new items or item files after the backup, the Content Library Service has no record of the new items or files after the restore operation. A warning notifies you that extra folders or files were found on the storage backup.

If you create new libraries after the backup, the Content Library Service has no record of the new libraries after restore. The library content exists on the storage backing, but no warning is displayed. You must manually clean the new libraries.

Virtual Machine Life Cycle Operations

- Restoring vCenter from a backup that was taken while there are in-flight relocation operations within the vCenter instance.

  After you restore vCenter, the vCenter view of the virtual machines may be out of sync with the ESX view of the virtual machines. This is also true if you performed the backup while there were in-flight operations on vCenter. If virtual machines disappear after you restore vCenter, you can refer to the following cases.

  a. The missing virtual machine is located on the destination ESX host and is registered with the destination ESX host, but it is not in the vCenter inventory. You must manually add the virtual machine to the vCenter inventory.
  b. The missing virtual machine is located on the destination ESX host, but it is not registered with the destination ESX host and it is not in the vCenter inventory. You must manually register the virtual machine to the ESX and add the virtual machine back to the vCenter inventory.
  c. The missing virtual machine is located on the destination ESX host, but it is not registered with the destination ESX host. Within the vCenter instance, the missing virtual machine is marked as orphaned. You must remove the virtual machine from the vCenter inventory and add it again.
- Restoring vCenter from a backup that has an out of date linked clone virtual machine layout.

  If you create a linked clone virtual machine after the backup and you restore vCenter from the old backup, then after the restore, vCenter does not know about the new linked clone virtual machine until vCenter discovers the new linked clone virtual machine. If you remove all existing virtual machines before the new linked clone virtual machine is discovered, then the removal of existing virtual machines corrupts the new linked clone due to missing disks. To avoid this corruption, you must wait until all linked clone virtual machines get discovered by the vCenter before you remove virtual machines.

vSphere High Availability

Restoring vCenter from a backup may cause it to roll back to older version for the vSphere HA cluster state (HostList, ClusterConfiguration, VM protection state) while the hosts in the cluster have the latest version for the cluster state. Ensure that the vSphere HA cluster state stays the same during restore and backup operations. Otherwise, the following potential problems are present.

- If hosts are added or removed to/from the vSphere HA cluster after backup and before vCenter restore, virtual machines could potentially fail over to hosts not managed by the vCenter but are still part of the HA cluster.
- Protection states for new virtual machines are not updated on the vSphere HA agents on the hosts which are part of the vSphere HA cluster. As a result, virtual machines are not protected/unprotected.
- New cluster configuration state is not updated on the vSphere HA agents on the hosts which are part of the vSphere HA cluster.

vCenter High Availability

Restoring vCenter requires vCenter HA to be reconfigured.

Storage Policy Based Management

Restoring vCenter from a backup can lead to the following inconsistencies related to storage policies, storage providers, and virtual machines.

- Registered storage providers after backup are lost.
- Unregistered storage providers after backup reappear and might show different provider status.
- Changes, such as create, delete, or update, performed on storage policies after backup are lost.
- Changes, such as create, delete, or update, performed on storage policy components after backup are lost.
- Default policy configuration changes for datastores performed after backup are lost.
- Changes in the storage policy association of the virtual machine and its disks, and in their policy compliance might occur.

Virtual Storage Area Network

Restoring vCenter from a backup may cause inconsistencies in the vSAN. For information how to check vSAN health, see Monitoring vSAN Skyline Health.

Patching

Restoring vCenter from a backup might result in missing security patches. You must apply them again after the restore is complete. For information on patching the vCenter appliance, see vCenter Upgrade.

Restore a vCenter Image-based Environment

You can use a third-party product that uses vSphere APIs to restore a virtual machine that contains vCenter.

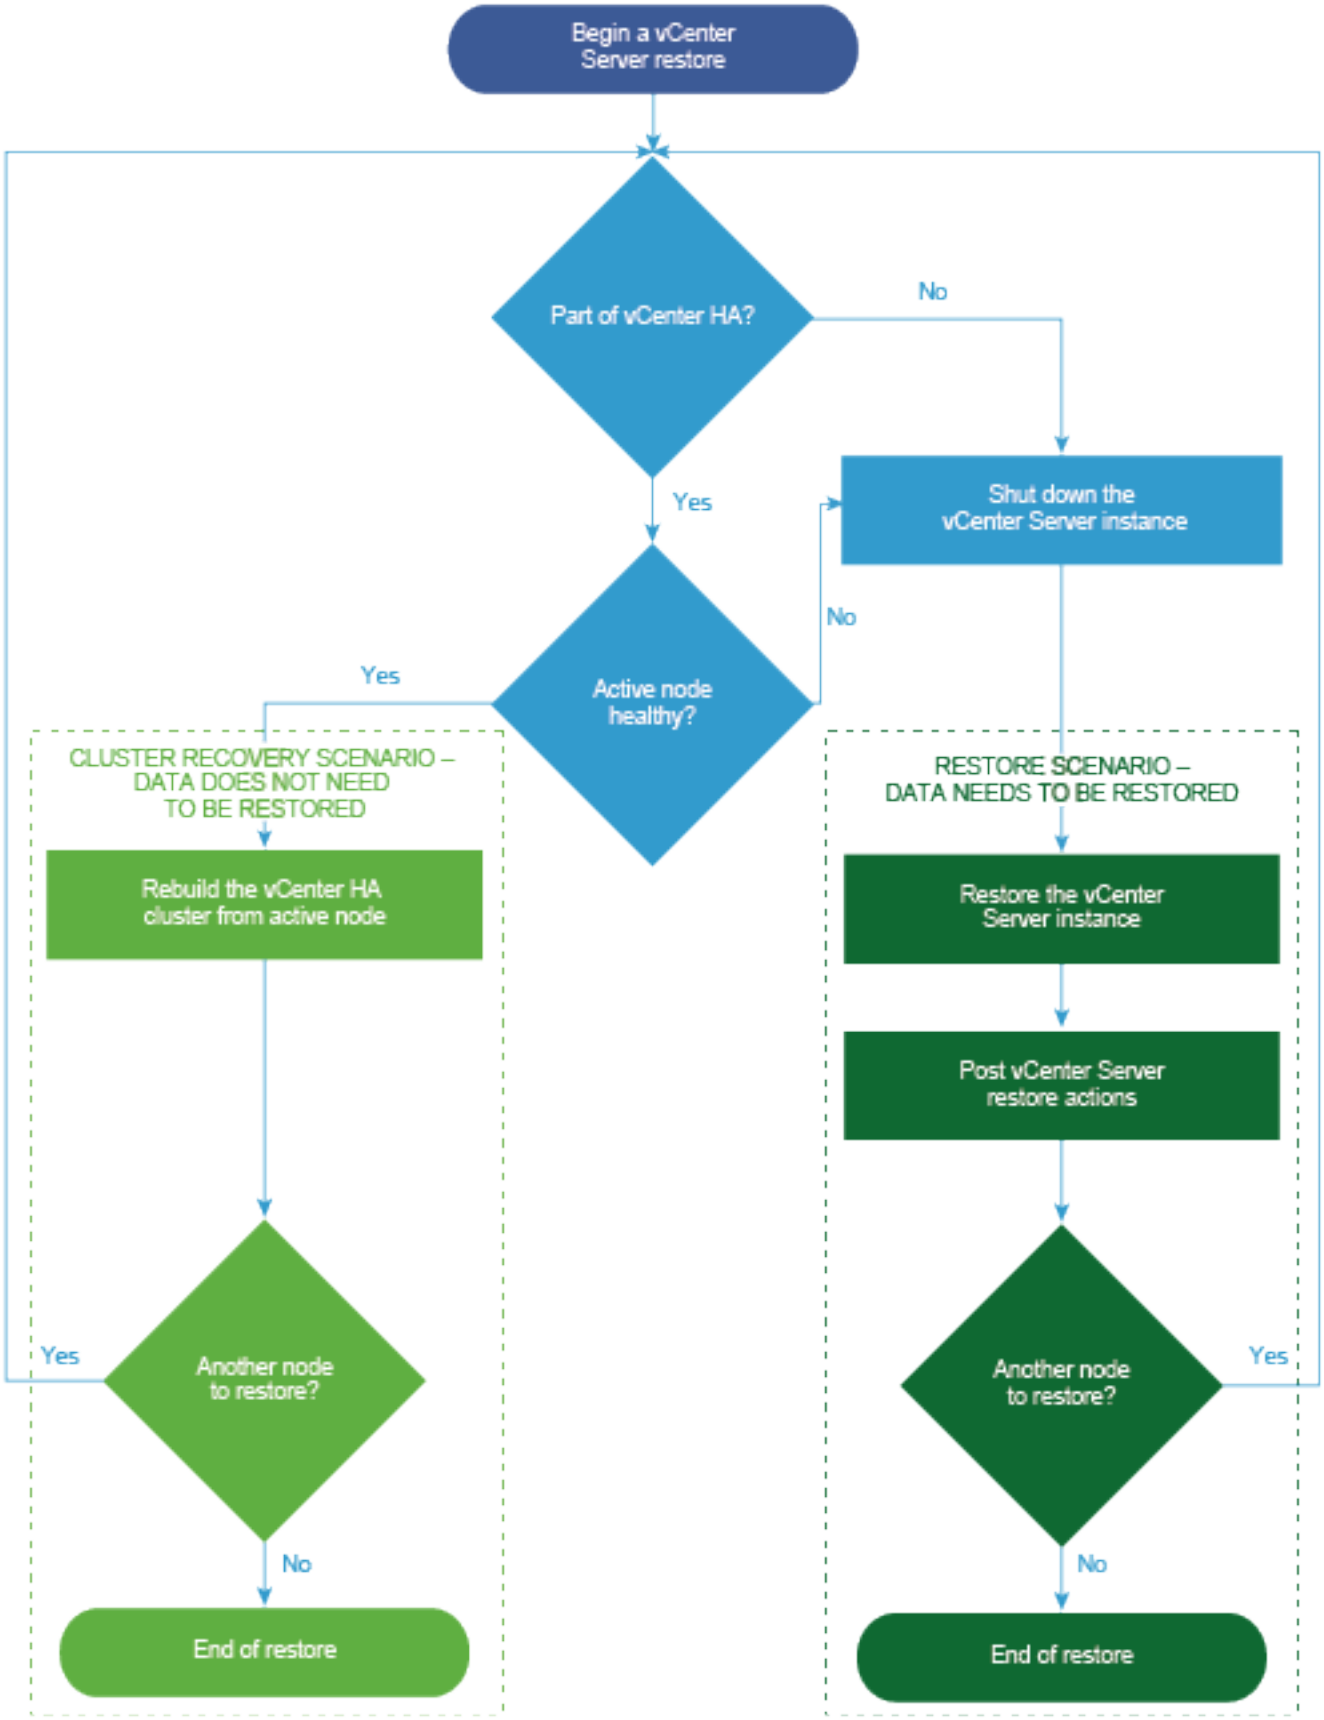
You can perform an image-based restore of a virtual machine that contains vCenter. The virtual machine must use a fully qualified domain name (FQDN) with correct DNS resolution, or the host name of the machine must be configured to be an IP address.

You can restore a virtual machine to the original location by either overwriting the backed up virtual machine or by creating a new virtual machine that contains the restored vCenter on the same ESX host. You can also restore the virtual machine on a new ESX host.

You can restore a virtual machine that contains vCenter directly on the ESX host that is running the third-party appliance when the vCenter service becomes unavailable or when you cannot access the third-party user interface by using the vSphere Client.

> **Important:**
> Restoring virtual machines that have snapshots or that are configured with Fault Tolerance is unsupported.

Figure 18: vCenter Restore Workflow



Restore a vCenter Instance

You can use a third-party product to restore a vCenter environment.

Important:
You can back up and restore only virtual machines that contain vCenter instances. You cannot back up and restore physical machines that are running vCenter by using a third-party product.

1. Restore the vCenter virtual machine onto the ESX host using a third-party solution.
2. Use the `service-control --status --all` command to verify that the services have started.
   Wait for all the vCenter services to start, which can take several minutes.
3. Launch the vCenter Management Interface, https://*appliance-IP-address-or-FQDN*:5480.
4. When you launch the vCenter Management Interface, based on the change in the vCenter appliance data you will see one of the following:
   a) If there is a change in the vCenter appliance data that needs to be synchronized, reconciliation window will be displayed. Follow the prompts to complete the reconcilation and then provide the Single Sign-On credentials to log into the vCenter Management Interface.
   b) If there is no change in the vCenter appliance data, the vCenter Management Interface login screen will be displayed.

Power on the restored virtual machine that contains the restored vCenter instance.

Restore a vCenter Enhanced Linked Mode Environment

You can restore a vCenter Enhanced Linked Mode environment using a third-party solution.

Important:
You can back up and restore only virtual machines that contain vCenter instances. You cannot back up and restore physical machines that are running vCenter by using a third-party product.

1. Restore the vCenter virtual machine onto the ESX host using a third-party solution.
   The services are masked and are not yet running.
2. Use the `systemctl status applmgmt` command to verify that the `systemd` instance of the `applmgmt` service has started.
   Wait for all the vCenter services to start, which can take several minutes.
3. Log in to the vCenter Management Interface, https://*appliance-IP-address-or-FQDN*:5480.

Power on the restored virtual machine that contains the restored vCenter instance.

After You Deploy the vCenter Appliance

After you deploy the appliance, consider these post installation options before adding inventory for the vCenter to manage.

If you plan to install Windows 11 as a guest operating system on a virtual machine, you must configure a key provider. Installing Windows 11 requires a Trusted Platform Module (TPM) 2.0. When installing Windows 11 as a guest operating system on a virtual machine, instead of using a physical TPM, you can use a virtual Trusted Platform Module (vTPM). A vTPM is a software-based representation of a physical TPM 2.0 chip. A vTPM depends on virtual machine encryption to secure vital TPM data, and so requires that you configure a key provider. For information about the key providers supported by vSphere, see the Virtual Machine Encryption chapter in the *vSphere Security* documentation. The easiest way is to configure a VMware vSphere®Native Key Provider™. vSphere Native Key Provider is included in all vSphere editions and does not require an external key server. For information about configuring a vSphere Native Key Provider, see Configuring and Managing vSphere Native Key Provider chapter in the *vSphere Security* documentation. As with all security solutions, consider the system design, implementation considerations, and tradeoffs of using vSphere Native Key Provider.

For information about configuring the vSphere Authentication Proxy service, see Start the vSphere Authentication Proxy Service in *vSphere Security*.

For information about upgrading vCenter, see the vCenter Upgrade documentation.

Log in to Your vCenter by Using the vSphere Client

Learn how to use the vSphere Client to log in to vCenter and manage your vSphere inventory.

The vSphere Client is automatically installed as part of the vCenter appliance deployment. This way, the vSphere Client always points to the same vCenter Single Sign-On instance.

1. Open a web browser and enter the URL for your vCenter instance: `https://vcenter_IP_address_or_fqdn`
   As an alternative, you can open a web browser and enter the URL for the vSphere Client: `https://vcenter_IP_address_or_fqdn/ui`.
2. If a warning message about a potential security risk appears, select to continue to the website.

Browser	Action
Microsoft Edge	1. Click **Details**. 2. Under the additional message that appears, click **Go on to the webpage**.
Mozilla Firefox	1. Click **Advanced**. 2. Under the additional message that appears, click **Accept the Risk and Continue**.
Google Chrome	1. Click **Advanced**. 2. Under the additional message that appears, click **Proceed to** *vcenter_IP_address_or_fqdn*.

3. If the warning message about a potential security risk appears again, repeat Step 2.
4. You can log in through vCenter Single Sign-On or your local user account.

The vSphere Client connects to all the vCenter systems on which the specified user has permissions, and you can view and manage the vSphere inventory.

Repoint vCenter to Another vCenter in a Different Domain

You can move a vCenter from one vCenter Single Sign-On domain to another vCenter Single Sign-On domain. Services such as tagging and licensing are retained and migrated to the new domain.

The following use cases are supported:

- You can migrate a vCenter from an existing domain to an another existing domain with or without replication. The migrated vCenter moves from its current vCenter Single Sign-On domain and joins the other existing domain as another vCenter connected via enhanced linked mode.
  - See Repoint a Single vCenter Node to an Existing vCenter Single Sign-On Domain without a Replication Partner for instructions on repointing a single embedded node from one domain to an existing domain without a replication partner.
  - See Repoint a vCenter Node to an Existing vCenter Single Sign-On Domain with a Replication Partner for instructions on repointing an embedded node from one domain to an existing domain using replication.
- You can migrate a vCenter from an existing domain to a newly created domain (where the migrated vCenter is the first instance). See Repoint a vCenter Node to a New vCenter Single Sign-On Domain for instructions of this type of repointing. In this case, there is no replication partner.

Repoint a Single vCenter Node to an Existing vCenter Single Sign-On Domain without a Replication Partner

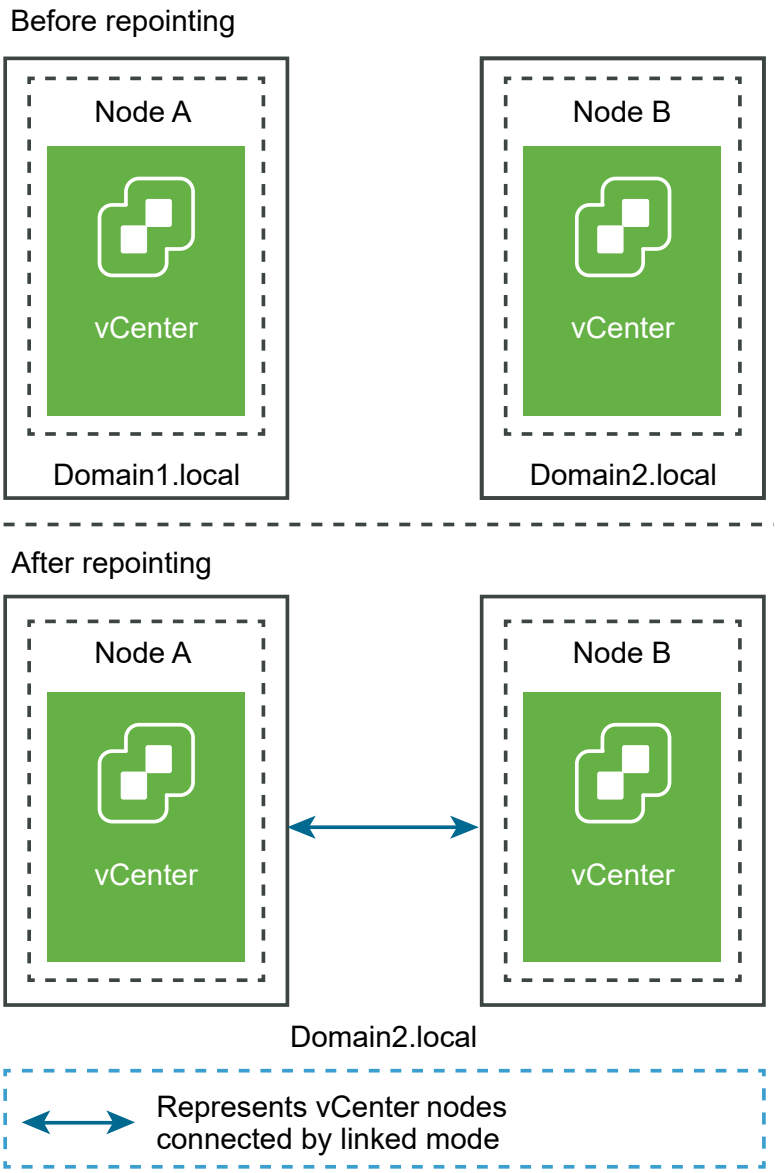
You can repoint a single vCenter from one vCenter Single Sign-On domain to an existing vCenter Single Sign-On domain without a replication partner. Each vCenter Single Sign-On domain contains a single vCenter.

- Repointing is only supported with vCenter 6.7 Update 1 and later.

- You must repoint to a vCenter that is of the same version and nodes that are of the same version and build number.
- To ensure no loss of data, take a file-based backup of each node before proceeding with repointing the vCenter.

See Figure: Repointing a Single from One Domain to an Existing Domain for an example of repointing a single vCenter from one domain to another existing domain. This is one of many ways to create an Enhanced Linked Mode node. In this case, there is no replication.

Figure 19: Repointing a Single vCenter from One vCenter Single Sign-On Domain to an Existing vCenter Single Sign-On Domain



1. Make sure that both vCenter nodes are powered on before beginning the repointing process.
2. Optional: Run the pre-check mode command. The pre-check mode fetches the tagging (tags and categories) and authorization (roles and privileges) data from the vCenter. Pre-check does not migrate any data, but checks for conflicts between the source and destination vCenter. For example, run the pre-check with the following CLI:

   ```
   cmsso-util domain-repoint -m pre-check --src-emb-admin Administrator --replication-partner-fqdn FQDN_of_destination_node --replication-partner-admin PSC_Admin_of_destination_node --dest-domain-name destination_PSC_domain
   ```

   Note:
   Pre-check is not required if a replication partner does not exist (repointing to a newly created domain).

See Syntax of the Domain Repoint Command for argument definitions for the `cmsso-util domain-repoint` command.

The pre-check writes the conflicts to the `/storage/domain-data` directory.

3. Optional: Review the conflicts and apply resolutions for all conflicts, or apply a separate resolution for each conflict.

   The conflict resolutions are:

   - Copy: Create a duplicate copy of the data in the target domain.
   - Skip: Skips copying the data in the target domain.
   - Merge: Merges the conflict without creating duplicates.

   Note:
   The default resolution mode for Tags and Authorization conflicts is Copy, unless overridden in the conflict files generated during pre-check.

4. Run the `execute` command. In execute mode, the data generated during the pre-check mode is read and imported to the target node. Then, the vCenter is repointed to the target domain. For example, repointing without a replication partner, run the `execute` command with the following:

   ```
   cmsso-util domain-repoint -m execute --src-emb-admin Administrator --replication-partner-
   fqdn FQDN_of_destination_node --replication-partner-admin PSC_Admin_of_destination_node --dest-domain-
   name destination_PSC_domain
   ```

   See Syntax of the Domain Repoint Command for argument definitions for the `cmsso-util domain-repoint` command.

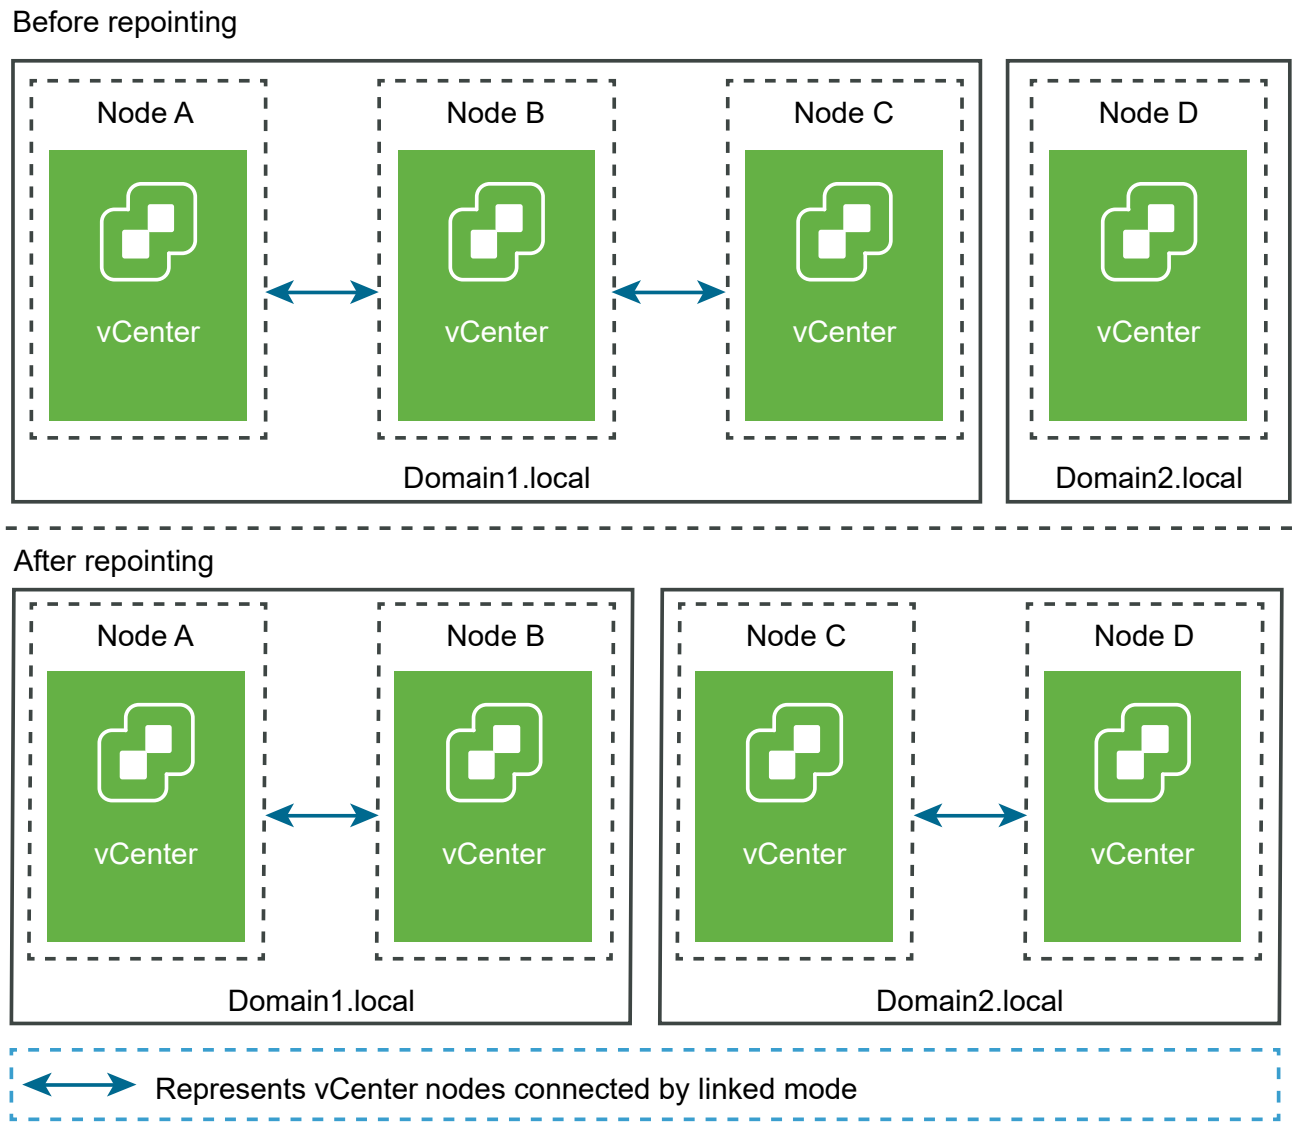
Repoint a vCenter Node to an Existing vCenter Single Sign-On Domain with a Replication Partner

You can repoint a vCenter from one vCenter Single Sign-On domain to an existing vCenter Single Sign-On domain using a replication partner.

- Repointing is only supported with vCenter 6.7 Update 1 and later.
- You must repoint to a vCenter that is of the same version and nodes that are of the same version and build number.
- To ensure no loss of data, take a file-based backup of each node before proceeding with repointing the vCenter.

See Figure 20: Repointing a vCenter from One vCenter Single Sign-On Domain to an Existing vCenter Single Sign-On Domain for an example of repointing to an existing domain. In this case, there is replication.

Figure 20: Repointing a vCenter from One vCenter Single Sign-On Domain to an Existing vCenter Single Sign-On Domain



1. Shut down the node (for example, Node C) that is being repointed (moved to a different domain).
2. Decommission the vCenter node that is being repointed. For example, to decommission Node C, log into Node B (on the original domain) and run the following command:

   ```
   cmsso-util unregister --node-pnid Node_C_FQDN --username Node_B_sso_administrator@sso_domain.com --
   passwd Node_B_sso_adminuser_password
   ```

   After unregistering Node C, services are restarted. References to Node C are deleted from Node B and any other nodes that were linked with Node C on the original domain.
3. Power on Node C to begin the repointing process.
4. Optional: Run the pre-check mode command. The pre-check mode fetches the tagging (tags and categories) and authorization (roles and privileges) data from the vCenter. Pre-check does not migrate any data, but checks the conflicts between the source and destination vCenter. For example, run the pre-check with the following CLI:

   ```
   cmsso-util domain-repoint -m pre-check --src-emb-admin Administrator --replication-partner-
   fqdn FQDN_of_destination_node --replication-partner-admin PSC_Admin_of_destination_node --dest-domain-
   name destination_PSC_domain
   ```

Note:
Pre-check is not required if a replication partner does not exist (repointing to a newly created domain).

See Syntax of the Domain Repoint Command for argument definitions for the `cmsso-util domain-repoint` command.

The pre-check writes the conflicts to the `/storage/domain-data` directory.

5. Optional: Check conflicts and apply resolutions for all conflicts or apply a separate resolution for each conflict.

   The conflict resolutions are:

   - Copy: Create a duplicate copy of the data in the target domain.
   - Skip: Skips copying the data in the target domain.
   - Merge: Merges the conflict without creating duplicates.

   Note:
   The default resolution mode for Tags and Authorization conflicts is Copy, unless overridden in the conflict files generated during pre-check.

6. Run the execute command. In execute mode, the data generated during the pre-check mode is read and imported to the target node. Then, the vCenter is repointed to the target domain. For example, run the execute command with the following:

   ```
   cmsso-util domain-repoint -m execute --src-emb-admin Administrator --replication-partner-fqdn FQDN
    _of_destination_node --replication-partner-admin destination_node_PSC_Admin_user_name --dest-domain-
   name destination_PSC_domain
   ```

   See Syntax of the Domain Repoint Command for argument definitions for the `cmsso-util domain-repoint` command.

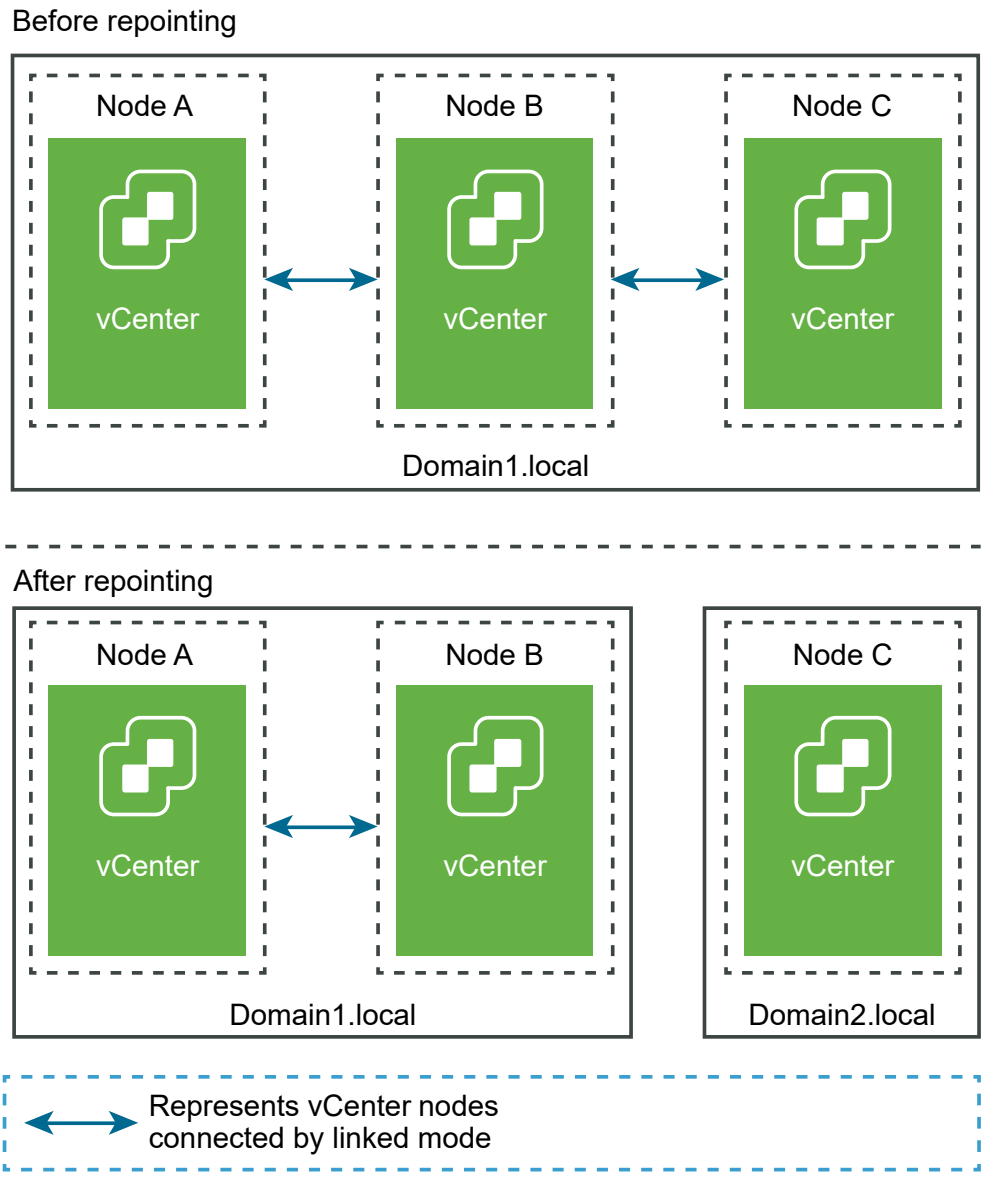
Repoint a vCenter Node to a New vCenter Single Sign-On Domain

You can repoint a vCenter from an existing vCenter Single Sign-On domain to a newly created vCenter Single Sign-On domain.

- Repointing is only supported with vCenter 6.7 Update 1 and later.
- You must repoint to a vCenter that is of the same version and nodes that are of the same version and build number.
- To ensure no loss of data, take a file-based backup and a snapshot in powered-off state of each node before proceeding with repointing the vCenter.

See Figure 21: Repointing a vCenter from One vCenter Single Sign-On Domain to a New vCenter Single Sign-On Domain for an example of repointing to a new domain. In this case, there is no replication partner.

Figure 21: Repointing a vCenter from One vCenter Single Sign-On Domain to a New vCenter Single Sign-On Domain



1. Shut down the node (for example, Node C) that is being repointed (moved to a different domain).

   Note:

   If the vCenter is part of a vCenter HA cluster, remove the vCenter HA configuration before proceeding with the domain repoint. For more information, see *vSphere Availability*.

2. Decommission the vCenter node that is being repointed. For example, to decommission Node C, log into Node B (on the original domain) and run the following command:

   ```
   cmsso-util unregister --node-pnid Node_C_FQDN --username Node_B_sso_administrator@sso_domain.com --
   passwd Node_B_sso_adminuser_password
   ```

   After unregistering Node C, services are restarted. References to Node C are deleted from Node B and any other nodes that were linked with Node C on the original domain.

3. Power on Node C to begin the repointing process.
4. Run the execute command. In execute mode, the data generated during the pre-check mode is read and imported to the target node. Then, the vCenter is repointed to the target domain. For example, repointing with no replication partner (repointing to a new domain), run the execute command with the following:

   ```
   cmsso-util domain-repoint -m execute --src-emb-admin Administrator --dest-domain-
   name destination_PSC_domain
   ```

   See Syntax of the Domain Repoint Command for argument definitions for the `cmsso-util domain-repoint` command.

Syntax of the Domain Repoint Command

You can use command arguments to set the execution parameters of the domain-repoint command.

The `cmsso-util domain-repoint` CLI repoints vCenter from one domain to another.

You can add a space-separated list of arguments to the CLI repoint command.

Use the following command to repoint a vCenter to another vCenter node:

```
cmsso-util domain-repoint -m execute --src-emb-admin Administrator --replication-partner-fqdn FQDN
 _of_destination_node --replication-partner-admin destination_node_PSC_Admin_user_name --dest-domain-
name destination_PSC_domain
```

Argument	Description
`-m`, `--mode`	*mode* can be `pre-check` or `execute`. The `pre-check` argument runs the command in pre-check mode. The `execute` argument runs the command in execute mode.
`-spa`, `--src-psc-admin`	SSO administrator user name for the source vCenter. Do not append the `@`*domain*.
`-dpf`, `--dest-psc-fqdn`	The FQDN of the vCenter to repoint.
`-dpa`, `--dest-psc-admin`	SSO administrator user name for the destination vCenter. Do not append `@`*domain*.
`-ddn`, `--dest-domain-name`	SSO domain name of the destination vCenter.
`-dpr`, `--dest-psc-rhttps`	(Optional) HTTPS port for the destination vCenter. If not set, the default `443` is used.
`-dvf`, `--dest-vc-fqdn`	The FQDN of the vCenter pointing to a destination vCenter. The vCenter is used to check for component data conflicts in the pre-check mode. If not provided, conflict checks are skipped and the default resolution (COPY) is applied for any conflicts found during the import process. **Note:** This argument is optional only if the destination domain does not have a vCenter. If a vCenter exists in the destination domain, this argument is mandatory.
`-sea`, `--src-emb-admin`	Administrator for the vCenter with embedded vCenter. Do not append `@domain` to the administrator id.
`-rpf`, `--replication-partner-fqdn`	(Optional) The FQDN of the replication partner node to which the vCenter is replicated.
`-rpr`, `--replication-partner-rhttps`	(Optional) The HTTPS port for the replication node. If not set, the default is `443`.
`-rpa`, `--replication-partner-admin`	(Optional) SSO administrator user name of the replication partner vCenter.
`-dvr`, `--dest-vc-rhttps`	(Optional) The HTTPS port for the vCenter pointing to the destination vCenter. If not set, the default `443` is used.
`--ignore-snapshot`	(Optional) Ignore snapshot warnings.
`--no-check-certs`	(Optional) Ignore certification validations.
`--debug`	(Optional) Retrieves command execution detail.
`-h`, `--help`	(Optional) Displays the help message for the `cmsso-util domain repoint` command.

Understanding Tagging and Authorization Conflicts

When you run the domain repoint command in pre-check mode, data from the vCenter is exported, examined, and conflicts are written to a file.

The following data is exported to the `/storage/domain-data/` or `ProgramData/VMWare/vCenterServerdata/domain-data` folder:

- `All_Privileges.json`
- `All_Roles.json`
- `All_TagCategories.json`
- `All_Tags.json`

These files contain the all the data (Authorization and Tagging) from the vCenter on which this command was run.

If a secondary vCenter is provided using the `-dvf` or `--dest-vc-fqdn` option, any conflicts are also exported to the same folder:

- `Conflicts_Roles.json`
- `Conflicts_TagCategories.json`
- `Conflicts_Tags.json`

The following is a sample conflicts file:

```
<---- Sample Conflict file code block --->
  {
  "global" : {
    "resolution" : "MERGE|SKIP|COPY",
    "description" : "Default resolution option used to resolve Role Conflicts is COPY. The
conflicts list describes the differences between Role entities on source and target vCenter instance. If
the source information represents an empty JSON array, it simply means that all the entity
attributes from source and target are identical. If the source lists few entries, it means
that only these entity attributes are missing from the target. If the target lists few entries,
it means that only these entity attributes are missing from the source. Though a global resolution
can be set, it can also be overridden at each conflict level by providing individual resolution
mode."
  },
  "conflicts-count" : 1,
  "conflicts-list" : {
    "NoCryptoAdmin" : {
      "source" : {
        "privileges" : "[]"
      },
      "target" : {
        "privileges" : "[Group-1.SamplePriv-1, Group-1.SamplePriv-4, Group-2.SamplePriv-10,
Group-2.SamplePriv-3, Group-2.SamplePriv-7, Group-3.SamplePriv-2, Group-3.SamplePriv-9]"
      },
      "resolution" : ""
    }
}
<----- End of code block --->
```

The parts of the sample conflict files are:

- `description`. Provides the details on how the respective conflicts file is read and understood.
- `source` and `target`. JSON objects that list only the differences between the source and target vCenter objects.
- `resolution`. User supplies one valid resolution. Valid resolutions are `MERGE`, `COPY`, and `SKIP`.

To specify the resolution for handling conflicts, you can provide a default resolution option all conflicts in the `"global": "resolution" = "MERGE|SKIP|COPY"` section. If you do not provide a valid global resolution type for `resolution` or leave it unedited, the system uses `COPY` as the default resolution option.

You can also provide a valid resolution option for each of the conflicts by editing the `resolution` property at each conflict level which overrides the global resolution option.

The types of conflicts listed in Table 49: Conflict Types.

Table 49: Conflict Types

Conflict	Properties used to compare Category Objects	Conflict Types	Conflicting Properties	Conflict Resolution Options
Role conflict	• `name`: Name of the category. • `privilegeId`: List of privileges for the role.	`RoleName` conflict occurs while importing roles and a role with the same name exists in the target vCenter but with different privileges.	Properties that can be conflicting for `RoleName` conflict type can be `Privileges`.	• `COPY`. A copy of the conflicting role is created in the target vCenter, with `--copy` appended to the role name. The new role is created with a new role ID with the same set of privilege IDs. The new role ID is updated in the `VPX_ACCESS` table. The new role ID is applicable for both role name conflict and role ID conflict. **Note:** The default resolution option to resolve Role conflicts is `COPY`. • `MERGE`.The `MERGE` option is resolved in the following sequence: a. If the source vCenter has a role with the same name and privilege list as a role in the target vCenter, but the role IDs are different, the role ID from the target vCenter is used and updated in the `VPX_ACCESS` table. b. If the source vCenter has a role with the same name as a role in the target vCenter, but with a different privilege list, then the privilege lists for both roles are merged. • `SKIP`. Do nothing. The specific role is skipped.
Tag Category conflict: A category name must be unique in a vCenter.	• `name`: Name of the category. • `cardinality`: Cardinality of Category, either Single or Multiple. • `associableEntityType`: List of vCenter object that can be associated with a tag from this category. A value of `All` indicates all vCenter objects.	Only one type of conflict can be seen while importing Tag Categories, `CategoryName` conflict. This conflict indicates that a category with the same name exists in the target vCenter but with different properties (`cardinality` or `associableEntityType`).	Properties that can be conflicting for conflict type `CategoryName` can be at least one of two types: `Cardinality` or `AssociableTypes`.	• `COPY`. A copy of the conflicting category is created in the target vCenter, with `--copy` appended to the category name. The new category is created with the same property name as in the source vCenter. All the tags that were present under this category is imported under the newly created `CategoryCopy`. **Note:** The default resolution option to resolve `CategoryName` conflicts is `COPY`. • `MERGE`. Conflicting properties are merged with the category that is already present in the SSO. Properties are merged as follows: 1. `Description`. The description that is already present is used. 2. `Cardinality`. Cardinality cannot shrink. If there is a cardinality conflict, the cardinality is set to `multiple`. It cannot be reduced to single.

Conflict	Properties used to compare Category Objects	Conflict Types	Conflicting Properties	Conflict Resolution Options
Tags Conflict: A `tag` object always belongs to a `category` Object. A tag Name must be unique only inside a category.	• `name` • `description`	Only one type of conflict can be seen while importing tags: `TagName` conflict. This conflict indicates that a Tag with the same name exists under the same category and in the target vCenter but with different properties.	Properties that can be conflicting for a conflict of type: `TagName` can be `Description`.	• `COPY`. A copy of the conflicting tag is created in the target vCenter, with `--copy` appended to the tag name. Take the `MoRef`(Internal tag ID) of the newly created tag and update the tag association if necessary. **Note:** The default resolution option to resolve `CategoryName` conflicts is `COPY`. • `MERGE`.Keep the existing description. Take the `MoRef`(Internal Tag ID) and update one or more Tag Associations if necessary. • `SKIP`. Do nothing. Do not create this tag. Clean up any Tag Associations.

vCenter Domain Repoint License Considerations

Domain repointing copies license keys to a new domain. Copying the license keys ensures that valid licensing of all assets is maintained after repointing.

For more information about cross-domain repointing, see "Repoint vCenter to Another vCenter in a Different Domain" in *vCenter Deployment and Setup*.

License Keys Not in Use in a Domain

If after completing repointing, a license key appears in more than one domain, but is not in use in some of those domains, you can remove the license key from any domain in which it is not in use.

License Keys in Use in Multiple Domains

If after completing repointing, a license key is in use (that is, assigned to assets) in more than one domain, to remove the license key from all but one domain, first a different license key must be assigned to each asset in domains from which the license key will be removed. Two common approaches:

- If you have other license keys available with sufficient unused capacity, you might use these other keys in place of a license key to be removed.
- You might divide the license keys used in more than one domain into separate license keys, one for each domain. To divide the license keys, see Broadcom knowledge base article 281796.

  Each of the resulting license keys can then be added to a different domain and assigned in vCenter to assets previously licensed with the original license key.

Troubleshooting vCenter Deployment

The vCenter deployment troubleshooting topics provide solutions to problems that you might encounter during the vCenter appliance deployment process.

Collecting Logs for Troubleshooting a vCenter Deployment or Upgrade

You can collect installation or upgrade log files for vCenter. If a deployment or upgrade fails, checking the log files can help you identify the source of the failure.

You can also collect deployment log files for vCenter.

Retrieve Installation Logs Manually

You can retrieve the installation log files manually for examination.

1. Navigate to the installation log file locations.
   - `%PROGRAMDATA%\VMware\vCenterServer\logs` directory, usually `C:\ProgramData\VMware\vCenterServer\logs`
   - `%TEMP%` directory, usually `C:\Users\`*`username`*`\AppData\Local\Temp`

   The files in the `%TEMP%` directory include `vc-install.txt`, `vminst.log`, `pkgmgr.log`, `pkgmgr-comp-msi.log`, and `vim-vcs-msi.log`.

   Note:
   - In Linux, the installation logs are in `/tmp/vcsaUiInstaller`
   - In MacOS, the installation logs are in `/var/folders/**/vcsaUiInstaller`
     The installer randomly picks a temporary folder to place the log files. Locate the `vcsaUiInstaller` folder within `/var/folders/` for the log files.
2. Open the installation log files in a text editor for examination.

Collect Deployment Log Files for the vCenter Appliance

If the vCenter appliance deployment fails, you can retrieve the log files and examine them for the reason of the failure.

The full path to the log files is displayed in the vCenter appliance deployment wizard.

In case of firstboot failure, you can download the support bundle on a Windows host machine and examine the log files to determine which firstboot script failed. See Export a vCenter Support Bundle for Troubleshooting.

1. On the Windows machine that you use for deploying the vCenter appliance, navigate to the log files folder.
   You must have administrator privilege to access the log files and the log files are available at:
   - Windows: `C:\Users\{user name}\AppData\Local\Temp\vcsaUiInstaller`
   - Linux: `/tmp/vcsaUiInstaller`
   - Mac : `/var/folders/**/**/**/vcsaUiInstaller`
2. Open the installation log files in a text editor for examination.

Export a vCenter Support Bundle for Troubleshooting

You can export the support bundle of the vCenter instance in the appliance for troubleshooting using the URL displayed on the DCUI home screen.

You can also collect the support bundle from the vCenter appliance Bash shell by running the `vc-support.sh` script.

The support bundle is exported in `.tgz` format.

1. Log in to the Windows host machine on which you want to download the bundle.
2. Open a Web browser and enter the URL to the support bundle displayed in the DCUI.
   https://*`appliance-fully-qualified-domain-name`*:443/appliance/support-bundle
3. Enter the user name and password of the root user.
4. Click **Enter**.
   The support bundle is downloaded as `.tgz` file on your Windows machine.
5. Optional: To determine which firstboot script failed, examine the `firstbootStatus.json` file.
   If you ran the `vc-support.sh` script in the vCenter appliance Bash shell, to examine the `firstbootStatus.json` file, run
   ```
   cat /var/log/firstboot/firstbootStatus.json
   ```

vCenter Upgrade

vCenter Upgrade describes how to upgrade VMware vCenter™ to the current version.

At VMware, we value inclusion. To foster this principle within our customer, partner, and internal community, we create content using inclusive language.

Intended Audience

vCenter Upgrade is for anyone who must upgrade from earlier versions of vSphere. These topics are for experienced Microsoft Windows or Linux system administrators who are familiar with virtual machine technology and data center operations.

vSphere Upgrade Options

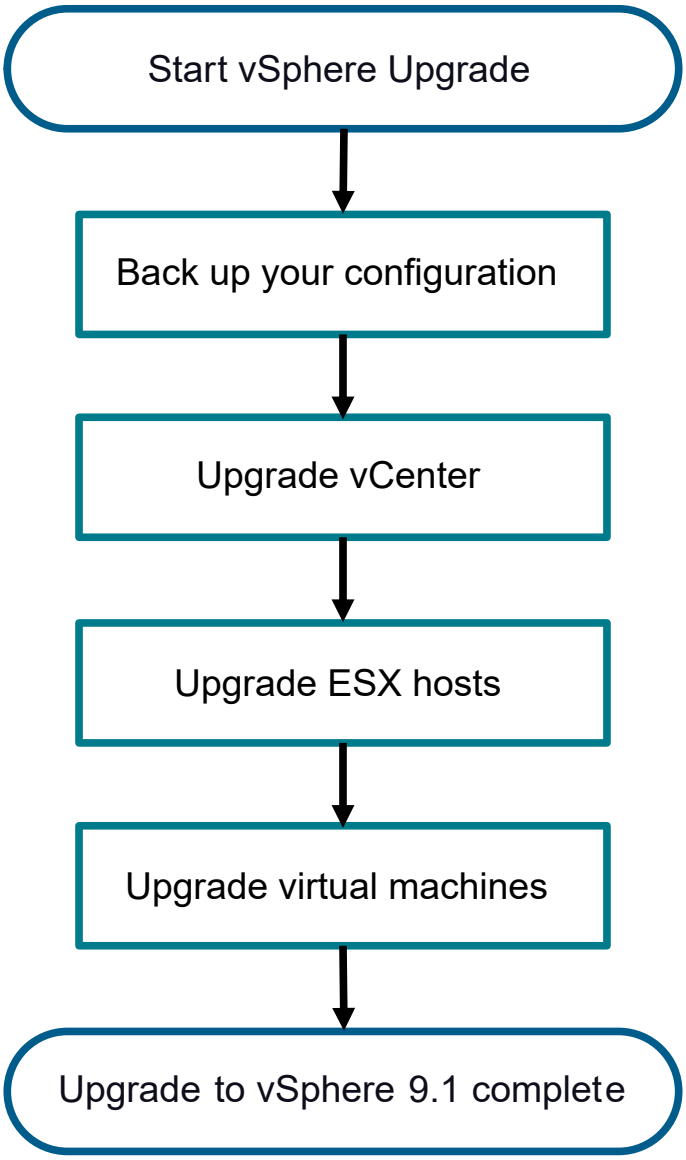
vSphere 9.1 provides many options for upgrading your vSphere deployment. For a successful vSphere upgrade, you must understand the upgrade options, the configuration details that impact the upgrade process, and the sequence of tasks.

The two core components of vSphere are VMware ESX™ and VMware vCenter™. ESX is the virtualization platform on which you can create and run virtual machines and virtual appliances. vCenter is a management plane that acts as a central administrator for ESX hosts connected in a network. You use the vCenter system to pool and manage the resources of multiple hosts.

How to Upgrade vSphere

vSphere is a sophisticated product with multiple components to upgrade. Understanding the required sequence of tasks is vital for a successful vSphere upgrade.

Figure 22: Overview of vSphere Upgrade Tasks



Upgrading vSphere includes the following tasks:

1. In the VMware Cloud Foundation Release Notes, read the information about VMware vCenter.
   See Release Notes.
2. Verify that you have backed up your configuration.
3. If your vSphere system includes VMware solutions or plug-ins, verify that they are compatible with the vCenter appliance version to which you are upgrading.
   See Product Interoperability Matrix.
4. Upgrade vCenter.
   See Overview of the vCenter Upgrade Process.
5. To ensure sufficient disk storage for log files, consider setting up a syslog server for remote logging. Setting up logging on a remote host is especially important for hosts with a limited amount of local storage.
   See Overview of the ESX Host Upgrade Process.
6. Optionally, upgrade your VM hardware version manually or by using vSphere Lifecycle Manager to perform an orchestrated upgrade.
   See Managing Host and Cluster Lifecycle.

When you upgrade vSphere, you must perform all procedures in the specified sequence to avoid possible data loss and to minimize downtime. You can perform the upgrade process for each component in only one direction. For example, after

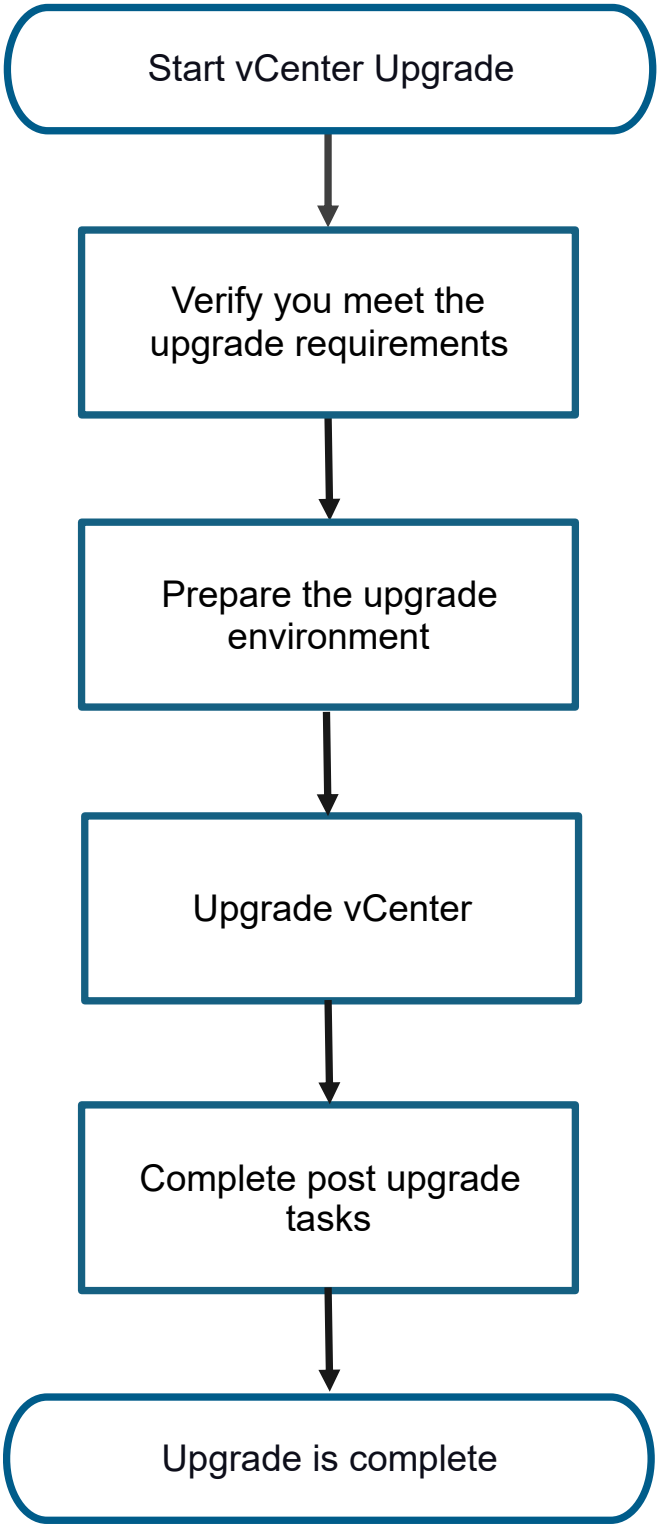
you upgrade to vCenter 9.1, you cannot revert to vCenter 9.0 or 7.0. With backups and some planning, however, you can restore your original vCenter environment.

Overview of the vCenter Upgrade Process

VMware provides many options to upgrade to vCenter 9.1 and later.

You can upgrade your vCenter version 8.0 and later installation to version 9.1 and later.

Figure 23: Overview of vCenter Upgrade Tasks



High-level steps for upgrading vCenter:

1. Verify that your system meets the hardware and software requirements. See .
2. Prepare your environment for the upgrade or migration.
3. Upgrade your vCenter appliance deployment.
4. Finish any required post-upgrade or post-migration tasks.

Concurrent upgrades are not supported and upgrade order matters.

vCenter Supported Upgrade Methods

Graphical User Interface (GUI) Installer	The GUI installer provides a two-step upgrade method using an OVA file that you deploy, and the vCenter Management Interface. The first step deploys a vCenter appliance using an OVA file. The second step uses the vCenter Management Interface to configure the new appliance using the source deployment data.
Command-Line Interface (CLI) Installer	The CLI installer provides advanced users with a CLI method for upgrading the vCenter appliance. You can upgrade to a vCenter appliance using customized CLI templates.
Deprecated vCenter Deployment Models	When upgrading from deprecated deployment models, you must first upgrade your deployment to a currently supported deployment model before attempting to upgrade it to a vCenter 9.1 deployment.
Patching and Updating vCenter	A patch or update brings the vCenter 9.1 software up to the current, minor version. You can use the patching process to make minor upgrades to your 9.1 deployment. See Differences Between vSphere Upgrades, Patches, and Updates and Patching and Updating vCenter 9.1 Deployments.

vCenter Upgrade Compatibility

Upgrading to vCenter 9.1 affects other software components of the data center.

Table 50: Upgrading vCenter and Related VMware Products and Components summarizes how upgrading vCenter can affect your data center components.

vCenter 9.1 and later can manage ESX version 9.0 hosts in the same cluster with ESX 9.1 hosts. vCenter 9.1 and later cannot manage ESX 7.0 or earlier hosts.

vSphere supports upgrades from vCenter 8.0 and later to vCenter 9.1 and later.

Table 50: Upgrading vCenter and Related VMware Products and Components

Product or Component	Compatibility
vCenter	Verify support for the upgrade path from your current version of vCenter to your planned upgrade version. See the Product Interoperability Matrix.
ESX hosts	Verify that your ESX host works with the vCenter version that you are upgrading to. vCenter 9.1 requires ESX host version 8.0 Update 1 or later. Upgrade if necessary. See the Product Interoperability Matrix.
VMware Host Profiles	Host Profiles is a vCenter tool for designing and deploying ESX hosts. Ensure that you are using Host Profiles version 6.0 or later. See Broadcom knowledge base article 318864. For more information on upgrade problems related to Host Profiles, see Upgrade Issues with vCenter Containing Host Profiles and the sections on Host Profiles upgrade workflows in the *vSphere Host Profiles* documentation.
VMFS volumes	You cannot upgrade a VMFS5 datastore to VMFS6. If you have a VMFS5 datastore in your environment, create a VMFS6 datastore and migrate virtual machines from the VMFS5 datastore to VMFS6. For more information on VMFS datastores, see vSphere VMFS Datastore Concepts and Operations in the *vSphere Storage* documentation.
Virtual machines	Upgrade options depend on your current version. For more information about upgrading virtual machines, see Upgrading Virtual Machines and VMware Tools in the *ESX Upgrade* documentation.
VMware Tools	Upgrade options depend on your current version. For more information, see Upgrading Virtual Machines and VMware Tools in the *ESX Upgrade* documentation.
Auto Deploy	To ensure compatibility and best performance, when you upgrade to vCenter 9.1, use Auto Deploy to upgrade ESX hosts to the same version.

Product or Component	Compatibility
vSphere Distributed Virtual Switch (DVS)	You must upgrade to DVS version 7.0 or later before you upgrade to vCenter 9.1.
vSphere Network I/O Control	DVS version 6.0 or later supports only Network I/O Control version 3. If you are using an earlier version of Network I/O Control you must upgrade to Network I/O Control version 3. For more information, see What is vSphere Network I/O Control in the *vSphere Networking* documentation.
vSAN	To avoid potential faults because of differences in the vSAN support in vCenter and ESX, synchronize the versions of vCenter and ESX. For the best integration between vSAN components on vCenter and ESX, deploy the latest version of these two vSphere components. For more information, see the ESX Installation and Setup, vSphere Deployment and Setup, and ESX Upgrade documentation. Specific vSAN configurations, such as a stretched cluster, require a witness host. Instead of using a dedicated physical ESX host as a witness host, you can deploy the vSAN witness appliance. For more information, see vSAN Witness Appliance.
vSAN disk version	vSAN has several different on-disk format versions available depending on the version and upgrade history of the cluster. Some on-disk format versions are transient while others are intended for long-term production. As certain vSAN features are tied to the on-disk format version, the format version must be accounted for when determining interoperability. See Broadcom knowledge base article 327034.

Differences Between vSphere Upgrades, Patches, and Updates

vSphere products distinguish between upgrades, which make major changes to the software, patches and updates, which make smaller changes to the software.

VMware product versions are numbered with two digits, for example, vSphere 9.1. A release that changes either digit, for example, 8.0 to 9.0, involves major changes in the software, and requires an upgrade from the previous version. A release that makes a smaller change, requiring only a patch or update, is indicated by an update number, for example, vSphere 8.0 Update 3 or vSphere 9.1.1 and vSphere 9.1.1.0100.

For information about upgrading vCenter installations, see Upgrading the vCenter Appliance.

For information about patching or updating vCenter, see Patching and Updating vCenter 9.1 Deployments.

When you upgrade an ESX host, some host configuration information is preserved in the upgraded version. After rebooting, the upgraded host can join a vCenter instance that has been upgraded to the same level. Because updates and patches do not involve major changes to the software, the host configuration is not affected. For more information, see the Overview of the ESX Host Upgrade Process article in the*ESX Upgrade* documentation.

Component Behavior Changes That Affect vCenter Upgrade

When upgrading to vCenter 9.1, it is important to understand changes in component behavior for version 9.1 that can affect the upgrade process.

Understanding changes from previous versions of vSphere can help in your upgrade planning. For a complete list of new features in vSphere 9.1, see the Release Notes for version 9.1 releases.

Upgrade Methods

There are multiple methods for upgrading vCenter to version 9.1.

Support for Graphical User Interface (GUI) Deployments of vCenter	You can upgrade an existing vCenter appliance version 9.0 deployment to vCenter 9.1 using the GUI. See GUI Upgrade of the vCenter Appliance.
Support for Command Line Interface (CLI) Deployments of vCenter appliance	You can upgrade an existing vCenter appliance version 9.0 deployment to vCenter 9.1 using the CLI. See CLI Upgrade of the vCenter Appliance .

Support for Reduced Downtime Upgrade through vSphere Client	You can use a migration-based approach to upgrade vCenter between major and minor versions that reduces downtime to several minutes. See Reduced Downtime Upgrade.

Changes in Supported Deployment Types

Changes from previous versions of vSphere can affect your deployment type.

Mixed IPv4 and IPv6 Upgrade

- Upgrade from vCenter 9.0 to 9.1 is supported for pure IPv4 or pure IPv6 management networks only.
- Using dual IP stacks (IPv4 and IPv6) is not supported.

Support for Upgrading a vCenter with Multi-Homing

When upgrading a vCenter appliance with two or more network interface cards (NICs), the upgrade transfers the IP addresses from each network interface from the source vCenter to the target vCenter.

During the upgrade process, the Upgrade installer performs a pre-check of the source vCenter and records the network settings. When this information is transferred to the target vCenter appliance, the network settings are transferred as part of the configuration. When the upgrade process finishes, you can log in to the vCenter appliance using the vSphere Client, and verify that the IP addresses have been successfully transferred to the newly upgraded vCenter appliance.

With two or more NICs per vCenter appliance, you can better manage network traffic in your environment. For example, with multiple network interfaces you can:

- Configure backup traffic to use a different network than management traffic.
- Keep ESX hosts on a physically different LAN segment from your management traffic. You can connect one network interface to the network with your ESX hosts, and connect the other to a network from which administrative clients connect to vCenter.

Support for Federal Information Processing Standard 140-2

vCenter 9.1 supports Federal Information Processing Standard (FIPS) 140-2.

FIPS 140-2 is a U.S. and Canadian government standard that specifies security requirements for cryptographic modules. By default, FIPS 140-2 is always activated after installation or upgrade of vCenter 9.1.

To learn more about support for FIPS 140-2 in VMware by Broadcom products, see https://www.vmware.com/security/certifications/fips.html.

To learn how to activate or deactivate FIPS 140-2 support, see Activate and Deactivate FIPS on the vCenter Appliance the *vSphere Security* documentation.

Support for Transport Security Layer 1.3

Starting in 8.0 Update 3, vSphere supports TLS 1.3 and 1.2 through the use of TLS profiles. By default, vSphere supports the Transport Security Layer (TLS) 1.3 encryption protocol.

Upgrading to vSphere 8.0 Update 3 activates the default TLS profile, named COMPATIBLE, on ESX and vCenter hosts. The COMPATIBLE profile supports TLS 1.3 and some TLS 1.2 connections.

To learn how to manage TLS configuration, see vSphere TLS Configuration in the *vSphere Security* guide.

Upgrading the vCenter Appliance

You can upgrade the vCenter appliance 8.0 or later to 9.1 only in the context of VMware vSphere Foundation or VMware Cloud Foundation. All the installation files that are necessary for the upgrade are included in the vCenter installer, which you can download from the Broadcom Support portal.

Note:

Before upgrading the vCenter appliance 8.0 or later to 9.1, you must upgrade your components in a specific sequence:

- For upgrading to VMware vSphere Foundation 9.1, you must first upgrade VMware Aria Operations 8.x to VMware Cloud Foundation Operations 9.1. See Upgrading to vSphere Foundation 9.1.
- For upgrading to VMware Cloud Foundation 9.1, see Upgrading to VMware Cloud Foundation 9.1.
- For upgrading vSphere 8.0 and later and Aria Operations 8.18 and later, see Upgrading vSphere 8 and Aria Operations 8 to 9.1.
- If the vSphere Lifecycle Manager database in your environment is reset, before upgrading vCenter see Broadcom knowledge base article 455737.

For information on the upgrade compatibility of vCenter, see the Broadcom Product Interoperability Matrix.

The upgrade of the vCenter appliance is a migration of the old version to the new version, which includes deploying a new vCenter appliance of version 9.1. You can deploy the new appliance on an ESX host 8.0 Update 1 or later, or on the inventory of a vCenter instance 8.0 or later. You assign a temporary IP address to the new appliance to facilitate the configuration and services data migration from the old appliance to the newly deployed appliance. After the migration, the IP address and host name of the old appliance are applied to the new upgraded appliance of version 9.1. At the end of the upgrade, the temporary IP address is released and the old appliance is powered off.

Version 9.1. of vCenter uses an embedded PostgreSQL database. During the upgrade, you must select a storage size for the new appliance that is suitable for the database size.

vCenter 9.1 uses an embedded vSphere Lifecycle Manager service that allows you to perform centralized and simplified lifecycle management of clusters with ESX 9.0 hosts. vSphere Lifecycle Manager in vSphere 9.1 includes the functionality that Update Manager provided in earlier vSphere releases for ESX host upgrade and patching operations, and upgrade of virtual machine hardware and VMware Tools.

For information about the software included in the vCenter 9.1 , see What is the vCenter Appliance in *vCenter Deployment and Setup*.

The vCenter installer contains executable files for both GUI and CLI upgrades which you can use alternatively.

- The GUI upgrade is a two stage process. The first stage is a deployment wizard that deploys the OVA file of the new appliance on the target ESX host or vCenter instance. After the OVA deployment finishes, you are redirected to the second stage of the process that sets up and transfers the services and configuration data from the old appliance to the newly deployed appliance.
- The CLI upgrade method involves running a CLI command against a JSON file that you previously prepared. The CLI installer parses the configuration parameters and their values from the JSON file and generates an OVF Tool command that deploys the new appliance. The OVF Tool command also transfers services and configuration data and from the old appliance to the new appliance.

For information about the vCenter appliance upgrade requirements, see System Requirements for the vCenter Appliance.

Important:
If the appliance that you are upgrading is configured in a mixed IPv4 and IPv6 environment, only the IPv4 settings are preserved. For information on the transfer of networking configuration settings for mixed mode IPv4 and IPv6 deployments, see Mixed IPv4 and IPv6 Upgrade.

If you are deploying the vCenter appliance directly on an ESX host, non-ephemeral distributed virtual port groups are not supported and are not shown. After the upgrade, you can manually connect the appliance to the original non-ephemeral distributed virtual port group. This is not a limitation when deploying the appliance through a vCenter, and you can deploy to ephemeral or non-ephemeral distributed virtual port groups.

For information on the upgrade compatibility of vCenter, see the Broadcom Compatibility Guide.

For information about deploying the vCenter, see Introduction to vSphere Deployment and Setup in *vCenter Deployment and Setup*.

For information about configuring the vCenter, see How to Configure vCenter in *vCenter Configuration*.

About the Upgrade Process of the vCenter appliance

You can upgrade the vCenter appliance from version 9.0 to version 9.1.

Attention:

If your current vCenter appliance is version 7.0 or earlier, you must upgrade to version 8.0 or later before upgrading to version 9.1.

Important:
In environments with multiple instances of vCenter appliance, you cannot perform parallel upgrades. Each vCenter instance must be upgraded separately. The reason for this is that VMware Directory Services (`vmdird`) encounters replication problems with single-sign on and certificate information.

When you run the GUI or CLI upgrade, the process includes:

1. Deploying a new vCenter 9.1 with a temporary network configuration. If you are upgrading a vCenter, you must select a deployment size for the new appliance that is suitable for your vSphere environment size. You must also select a storage size for the new appliance that is suitable for the vCenter database.
2. Exporting the services and configuration data from the source appliance of version 9.0 that you want to upgrade.
   You must select the data types that you want to transfer to the new appliance.
3. Transferring the exported data to the newly deployed appliance.
   If you are deploying the appliance directly on an ESX host, non-ephemeral distributed virtual port groups are not supported and do not appear as options during the upgrade. After the upgrade, you can manually connect the appliance to the original non-ephemeral distributed virtual port group. This process is not a limitation when deploying the appliance through a vCenter, and you can deploy to ephemeral or non-ephemeral distributed virtual port groups.
4. If you are upgrading a vCenter appliance that uses an external Platform Services Controller, it is converted to a vCenter instance with those services embedded in the appliance.
   The new vCenter appliance contains all Platform Services Controller services, preserving the functionality and workflows, including authentication, certificate management, and licensing. It is no longer necessary nor possible to deploy and use an external Platform Services Controller. All Platform Services Controller services are consolidated into vCenter during the upgrade.
5. Powering off the source appliance. The new upgraded vCenter appliance appliance assumes the network configuration of the source appliance.

- For the new appliance requirements, see System Requirements for the vCenter Appliance.
- For the appliance upgrade preparation, see Preparing to Upgrade the vCenter appliance.
- For the appliance upgrade procedures, see Upgrading the vCenter Appliance.
- For the appliance post-upgrade procedures, see After Upgrading vCenter.

Preparing to Upgrade the vCenter appliance

Before you upgrade the vCenter appliance, you must download the vCenter installer ISO file and mount it to a network virtual machine or physical server from which you want to perform the upgrade.

The computer from which you upgrade the appliance must run on a Windows, Linux, or Mac operating system that meets the operating system requirements. See System Requirements for the vCenter Installer.

To avoid any issues due to expired VMware Certificate Authority (VMCA) root certificate and to minimize the downtime for their renewal, in vCenter 9.1 the VMCA root certificate and the solution user certificates are automatically renewed if they are set to expire in less than 2 years. The automatic certificate renewal is triggered as part of the vCenter upgrade process. After the vCenter system is successfully upgraded, the VMCA root certificate is valid for 10 years.

For more information about vCenter certificate management, see the vSphere Authentication documentation.

Before upgrading a vCenter appliance, you must prepare the ESX hosts in the inventory.

- Download and Mount the vCenter Installer
- Synchronizing Clocks on the vSphere Network
- Transferring Data from an Existing vCenter Appliance

- Prepare ESX Hosts for vCenter Appliance Upgrade

Transferring Data from an Existing vCenter Appliance

Data transfer happens as part of the upgrade downtime. You can choose how much data to transfer during the upgrade to control the length of the downtime and the storage the new appliance needs.

During the upgrade, you can transfer the minimum data required for the vCenter appliance to be operational, or historical event, task, and performance data, from the source appliance to the embedded PostgreSQL database of the new vCenter appliance. All transferred data is copied during the upgrade, and the original data on the source appliance remains unchanged.

You can migrate the following types of data to the embedded PostgreSQL database in use by version 9.1 of the vCenter appliance.

Configuration data	The minimum type of data you must transfer from your existing vCenter appliance to upgrade to a functioning vCenter appliance. This data can be transferred in a reasonably short amount of time, minimizing downtime during the upgrade to vCenter 9.1.
Configuration and historical data	In addition to the configuration data, you can choose to transfer historical data such as usage statistics, events, and tasks. The vCenter installer gives you the option to copy both the configuration and historical data at one time, or to copy only the configuration data during the upgrade process. You can then choose to copy the historical data in the background after you start your new vCenter 9.1. **Attention:** If you choose to copy all data at one time, you cannot start vCenter until all the data has been transferred to the embedded PostgreSQL database within vCenter 9.1.
Configuration, historical, and performance metrics data	The largest amount of data you can choose to transfer to vCenter. This option requires the longest transfer time and the largest storage footprint, and vCenter does not start until all the data has been transferred. To minimize the upgrade time and the storage required for the new appliance, select to transfer only the configuration data.

Prepare ESX Hosts for vCenter Appliance Upgrade

Before upgrading to vCenter 9.1, you must prepare your ESX hosts.

To upgrade vCenter appliance, your ESX hosts must meet the requirements for upgrade.

- ESX hosts must be at version 9.0 or later. For information on ESX compatibility, see the VMware by Broadcom Compatibility Guide.
- Your source and target ESX hosts must not be in lockdown or maintenance mode, and not part of fully automated DRS clusters.
- Review your environment's Certificate Authority (CA) signed SSL certificates. To learn about manually reviewing CA-signed SSL certificates in a vSphere environment, see Broadcom knowledge base article 321380.

1. If you have Custom or Thumbprint certificates, see ESX Host Upgrades and Certificates to determine your preparatory steps and certificate replacement behavior.

   If you use custom CA-signed certificates, ensure you review how to Change the ESX Certificate Mode to prevent VMCA from overwriting custom certificates.

2. If you have vSphere HA clusters, SSL certificate checking must be enabled.

   If certificate checking is not enabled when you upgrade ESX hosts, vSphere HA fails to configure on the hosts.

   a) Select the vCenter appliance instance in the vSphere Client inventory tree.
   b) Select the **Configure** tab, and then under **Settings** select **General**.
   c) Click **Edit**.
   d) Select **SSL settings**.

      Verify that **vCenter requires verified host SSL certificates** is selected.

Your ESX hosts are ready for the vCenter appliance upgrade.

Prerequisites for Upgrading the vCenter Appliance

To ensure a successful upgrade of the vCenter appliance, you must perform the following required tasks and pre-checks before beginning the upgrade process.

General Prerequisites

- Download and Mount the vCenter Installer.
- Verify that the clocks of all systems on the vSphere network are synchronized. See Synchronizing Clocks on the vSphere Network.

Target System Prerequisites

- Verify that your system meets the minimum software and hardware requirements. See System Requirements for the vCenter Appliance.
- If you plan to deploy the new appliance on an ESX host, verify that the target ESX host is not in lockdown or maintenance mode.
- If you plan to deploy the new appliance on an ESX host managed by vCenter, review the Distributed Resource Scheduler (DRS) settings on the cluster. Ensure that the DRS settings for the cluster on which the target ESX host resides are not configured for Full Automation. Set the Automation Level to Manual or Partially Automated. This Automation Level ensures that the target ESX host does not reboot during the upgrade process.
- If you plan to deploy the new appliance on a DRS cluster of the inventory of a vCenter instance, verify that the cluster contains at least one ESX host that is not in lockdown or maintenance mode.

Source System Prerequisites

- If the source appliance is on a DRS cluster of the inventory of a vCenter instance and during upgrade:
  - If you plan to use the ESX host where the appliance resides, review the Distributed Resource Scheduler (DRS) settings on the cluster. Ensure that the DRS settings of the cluster is set to manual or partially automated so that the VMs of the source system do not move during the upgrade.
  - If you plan to use the vCenter instance where the appliance resides, you need not modify the DRS settings of the cluster.
- Verify that port 22 is open on the vCenter appliance that you want to upgrade. The upgrade process establishes an inbound SSH connection to download the exported data from the source vCenter appliance.
- Verify that port 443 is open on the source ESX host on which the appliance that you want to upgrade resides. The upgrade process establishes an HTTPS connection to the source ESX host to verify that the source appliance is ready for upgrade and to set up an SSH connection between the new and the existing appliance.

  Note:
  When upgrading, the temporary vCenter instance requires the same access rights as the permanent vCenter instance to port 443. Ensure that any firewalls in your environment allow both the temporary and permanent vCenter instances to access port 443.
- Verify that you have sufficient free disk space on the appliance that you want to upgrade so that you can accommodate the data for the upgrade.
- Create an image-based backup (snapshot) of the vCenter appliance you are upgrading as a precaution in case there is a failure during the upgrade process.

  Important:

  To take a pre-upgrade image-based backup in an Enhanced Linked Mode environment, power off all the vCenter appliances in your environment, and back up each node. After you have taken backups of all the nodes, you can restart them and proceed with the upgrade procedure.

  If the upgrade fails, delete the newly deployed vCenter appliance, and restore the vCenter appliance from backup. You must restore all the nodes in the environment from their backups. Failing to do so will cause the replication partners to be out of synchronization with the restored node.

  To learn about image-based backup, see Image-Based Backup and Restore of a vCenter Environment in *vCenter Deployment and Setup*.

Network Prerequisites

- Verify that the new appliance can connect to the source ESX host and vCenter instance on which resides the appliance that you want to upgrade.
- If you plan to assign a static IP address and an FQDN as a system name in the temporary network settings of the appliance, verify that you have configured the forward and reverse DNS records for the IP address.
- If you plan to assign a DHCP IP address in the temporary network settings of the new vCenter appliance, verify that the ESX host on which you want to deploy the new appliance is in the same subnet as the ESX host on which the existing vCenter appliance runs.
- If you plan to assign a DHCP IPv4 address in the temporary network settings of the new vCenter appliance, verify that the ESX host on which you want to deploy the new appliance is connected to at least one network that is associated with a port group which accepts MAC address changes. Consider the default security policy of a distributed virtual switch, which is to reject MAC address changes. For information about how to configure the security policy for a switch or port group, see What is Security Policy in *vSphere Networking*.

GUI Upgrade of the vCenter Appliance

You can use the GUI installer to perform an interactive upgrade of a vCenter appliance.

To perform the GUI upgrade, download the vCenter appliance installer to a client machine, run the Upgrade Wizard from the client machine, and provide the inputs for the deployment and setup of the new upgraded appliance.

The GUI upgrade process includes a series of two stages.

Figure 24: Stage 1 - OVA Deployment

The first stage walks you through the deployment wizard to get the deployment type of the source appliance that you want to upgrade and configure the new appliance settings. During this stage, you deploy the new appliance with temporary network settings. This stage finishes the deployment of the OVA file on the target server with the same deployment type as the source appliance and the appliance settings that you provide.

As an alternative to performing the first stage of the upgrade with the GUI installer, you can deploy the OVA file of the new vCenter appliance using the vSphere Client or VMware Host Client. To deploy the OVA file on an ESX host or vCenter instance 9.0 or later, you can also use the vSphere Client. After the OVA deployment, you must log in to the vCenter Management Interface of the newly deployed appliance to proceed with the second stage of the upgrade process.

Figure 25: Stage 2 - Appliance Setup

The second stage walks you through the setup wizard to select the data types to transfer from the old to the new appliance. The new appliance uses the temporary network settings until the data transfer finishes. After the data transfer finishes, the new appliance assumes the network settings of the old appliance. This stage finishes the data transfer, starts the services of the new upgraded appliance, and powers off the old appliance.

As an alternative to performing the second stage of the upgrade with the GUI installer, you can log in to the vCenter Management Interface of the newly deployed appliance, https://`FQDN_or_IP_address`:5480.

Required Information for Upgrading a vCenter Appliance 8.0 and Later to Version 9.1

The GUI upgrade wizard prompts you for information about the vCenter appliance (version 8.0 or later) that you want to upgrade, deployment information for the new vCenter appliance 9.1. It is a best practice to keep a record of the values that you enter.

You can use this worksheet to record the information that you need for upgrading a vCenter appliance.

Table 51: Required Information During Stage 1 of the Upgrade

Required for Upgrade of	Required Information	Default
All deployment types	FQDN or IP address of the source appliance that you want to upgrade.	-
	HTTPS port of the source appliance.	443
	vCenter Single Sign-On administrator user name of the source appliance. **Important:** The user must be administrator@*your_domain_name*.	administrator@vsphere.local
	Password of the vCenter Single Sign-On administrator user.	-
	Password of the root user of the source appliance.	-
All deployment types	FQDN or IP address of the source server on which resides that appliance that you want to upgrade. The source server can be either an ESX host or a vCenter instance. **Note:** The source server cannot be the vCenter appliance that you want to upgrade. In such cases, use the source ESX host.	-
	HTTPS port of the source server.	443
	User name with administrative privileges on the source server. • If your source server is an ESX host, use root. • If your source server is a vCenter instance, use *user_name*@*your_domain_name*, for example, administrator@vsphere.local.	-
	Password of the user with administrative privileges on the source server.	-
All deployment types	FQDN or IP address of the target server on which you want to deploy the new appliance. The target server can be either an ESX host or a vCenter instance. **Note:** The target server cannot be the vCenter appliance that you want to upgrade. In such cases, use an ESX host as a target server.	-
	HTTPS port of the target server.	443
	User name with administrative privileges on the target server: • If your target server is an ESX host, use root. • If your target server is a vCenter instance, use *user_name*@*your_domain_name*, for example, administrator@vsphere.local.	-
	Password of the user with administrative privileges on the target server.	-

Required for Upgrade of	Required Information	Default
All deployment types Only if your target server is a vCenter instance.	Data center from the vCenter inventory on which you want to deploy the new appliance. Optionally you can provide a data center folder.	-
	ESX host or DRS cluster from the data center inventory on which you want to deploy the new appliance.	-
All deployment types	The virtual machine name for the new vCenter 9.1 appliance. • Must not contain a percent sign (%), backslash (\), or forward slash (/). • Must be no more than 80 characters in length.	vCenter Appliance
All deployment types	Password for the root user of the appliance operating system. • Must contain only the lower ASCII character set without spaces. • Must be at least 8 characters, but no more than 20 characters in length. • Must contain at least one uppercase letter. • Must contain at least one lowercase letter. • Must contain at least one number. • Must contain at least one special character, for example, a dollar sign ($), hash key (#), at sign (@), period (.), or exclamation mark (!).	-
vCenter appliance 8.0 and later	Deployment size of the new vCenter appliance 9.1 for your vSphere environment. • Tiny Deploys an appliance with 2 CPUs and 12 GB of memory. Suitable for environments with up to 10 hosts or 100 virtual machines. • Small Deploys an appliance with 4 CPUs and 19 GB of memory. Suitable for environments with up to 100 hosts or 1,000 virtual machines. • Medium Deploys an appliance with 8 CPUs and 28 GB of memory. Suitable for environments with up to 400 hosts or 4,000 virtual machines. • Large Deploys an appliance with 16 CPUs and 37 GB of memory. Suitable for environments with up to 1,000 hosts or 10,000 virtual machines. • X-Large Deploys an appliance with 24 CPUs and 56 GB of memory. Suitable for environments with up to 2,000 hosts or 35,000 virtual machines.	The size of the source vCenter appliance determines the default deployment size. Using this information, the upgrade installer calculates the best size to use for your environment, which might be the same as your existing deployment, or calculated to the next largest size.
All deployment types	Name of the datastore on which you want to store the configuration files and virtual disks of the new 9.1 . **Note:** The installer displays a list of datastores that are accessible from your target server.	-
	Enable or deactivate **Thin Disk Mode**.	Disabled

Required for Upgrade of	Required Information	Default
All deployment types	Name of the network to which to connect the new vCenter appliance 9.1. **Note:** The installer displays a drop-down menu with networks that depend on the network settings of your target server. If you are deploying the appliance directly on an ESX host, non-ephemeral distributed virtual port groups are not supported and are not displayed in the drop-down menu. The network must be accessible from the source server on which resides that appliance that you want to upgrade. The network must be accessible from the physical client machine from which you perform the deployment.	-
	IP version for the appliance temporary address Can be either IPv4 or IPv6.	IPv4
	IP assignment for the appliance temporary address Can be either static or DHCP.	static
All deployment types Only if you use a static assignment for the temporary IP address.	Temporary system name (FQDN or IP address) The system name is used for managing the local system. The system name must be FQDN. If a DNS server is not available, provide a static IP address.	-
	Temporary IP address.	-
	For IPv4 version, a subnet mask as a dot decimal notation or a network prefix as an integer between 0 and 32. For IPv6 version, a network prefix as an integer between 0 and 128.	-
	Default gateway.	-
	DNS servers separated by commas.	-
All deployment types Only if you use a DHCP assignment with IPv4 version for the temporary IP address and a DDNS server is available in your environment.	Temporary system name (FQDN).	-

Table 52: Required Information During Stage 2 of the Upgrade

Required for	Required Information	Default
vCenter appliance 8.0 and later	Data types to transfer from the old appliance to the new vCenter appliance 9.1. In addition to the configuration data, you can transfer the events, tasks, and, performance metrics. **Note:** For minimum upgrade time and storage requirement for the new appliance, select to transfer only the configuration data.	-
vCenter appliance 8.0 and later	Join or do not participate in the VMware Customer Experience Improvement Program (CEIP). For information about the CEIP, see the Configuring Customer Experience Improvement Program section in *vCenter and Host Management*.	Join the CEIP.

Upgrade a vCenter Appliance 8.0 or later to Version 9.1 by Using the GUI

You can use the GUI installer to perform an interactive upgrade of a vCenter appliance 8.0 or later to vCenter appliance 9.1. You must run the GUI upgrade from a Windows, Linux, or Mac OS X machine that is in the same network as the appliance that you want to upgrade.

- See Prerequisites for Upgrading the vCenter Appliance.
- See Required Information for Upgrading a vCenter Appliance 8.0 and Later to Version 9.1.

Stage 1 - Deploy the OVA File of the New vCenter Appliance

With stage 1 of the upgrade process, you deploy the OVA file, which is included in the vCenter appliance installer, for the new vCenter appliance.

1. In the vCenter installer, navigate to the `vcsa-ui-installer` directory, go to the subdirectory for your operating system, and run the installer executable file.
   - For Windows OS, go to the `win32` subdirectory, and run the `installer.exe` file.
   - For Linux OS, go to the `lin64` subdirectory, and run the `installer` file.
   - For Mac OS, go to the `mac` subdirectory, and run the `Installer.app` file.
2. On the Home page, click **Upgrade**.
3. Review the Introduction page to understand the upgrade process and click **Next**.
4. Read and accept the license agreement, and click **Next**.
5. Connect to the source appliance that you want to upgrade.
   a) Enter the information about the source vCenter appliance that you want to upgrade, and click **Connect to Source**.

Option	Action
Appliance FQDN or IP address	Enter the IP address or FQDN of the vCenter appliance that you want to upgrade.
Appliance HTTPS port	If the source appliance uses a custom HTTPS port, change the default value to that of the custom port. The default port value is 443. Custom port values are supported beginning with vCenter appliance version 6.5 Update 2. If you are upgrading from earlier versions, you cannot specify a custom port.

   b) Enter the information about thevCenter Single Sign-On administrator and root user.

Option	Action
SSO user name	Enter the vCenter Single Sign-On administrator user name. **Important:** The user must be administrator@*your_domain_name*.
SSO password	Enter the password of the vCenter Single Sign-On administrator.
Appliance (OS) root password	Enter the password of the root user.

c) Enter the information about the source ESX host or vCenter instance on which resides the vCenter appliance that you want to upgrade and click **Next**.

Option	Description
Source server or host name	IP address or FQDN of the source ESX host or vCenter instance on which the vCenter appliance that you want to upgrade resides. **Note:** The source vCenter instance cannot be the vCenter appliance that you want to upgrade. In such cases, use the source ESX host.
HTTPS port	If the ESX host or vCenter instance uses a custom HTTPS port, change the default value. The default value is 443.
User name	User name of a user with administrative privileges on the ESX host or vCenter instance.
Password	Password of the user with administrative privileges on the ESX host or vCenter instance.

6. Verify that the certificate warning displays the SHA1 thumbprints of the SSL certificates that are installed on the source appliance and its source server, and click **Yes** to accept the certificate thumbprints.
7. Connect to the target server on which you want to deploy the new vCenter appliance.

Option	Steps
You can connect to an ESX host on which to deploy the new appliance.	1. Enter the FQDN or IP address of the ESX host. 2. Enter the HTTPS port of the ESX host. 3. Enter the user name and password of a user with administrative privileges on the ESX host, for example, the root user. 4. Click **Next**. 5. Accept the certificate warning, if any, by clicking **Yes**.
You can connect to a vCenter instance and browse the inventory to select an ESX host or DRS cluster on which to deploy the new appliance. **Note:** The target server cannot be the vCenter appliance that you want to upgrade. In such cases, use an ESX host as a target server.	1. Enter the FQDN or IP address of the vCenter instance. 2. Enter the HTTPS port of the vCenter instance. 3. Enter the user name and password of a vCenter Single Sign-On user with administrative privileges on the vCenter instance, for example, the administrator@*your_domain_name* user. 4. Click **Next**. 5. Accept the certificate warning, if any, by clicking **Yes**. 6. Select the data center or data center folder that contains the ESX host or DRS cluster on which you want to deploy the new appliance, and click **Next** **Note:** You must select a data center or data center folder that contains at least one ESX host that is not in lockdown or maintenance mode. 7. Select the ESX host or DRS cluster on which you want to deploy the new appliance, and click **Next**.

8. On the Set up target appliance VM page, enter a name for the new vCenter appliance, set the password for the root user, and click **Next**.

   The appliance name must not contain a percent sign (%), backslash (\), or forward slash (/) and must be no more than 80 characters in length.

   The password must contain only lower ASCII characters without spaces, at least eight characters, a number, uppercase and lowercase letters, and a special character, for example, an exclamation mark (!), hash key (#), at sign (@), or brackets (()).

Note:
The root password of the old appliance is not transferred to the new upgraded appliance.

9. Select the deployment size for the new vCenter appliance 9.1 for your vSphere inventory.

Deployment Profile	Description
Tiny	Deploys an appliance with 2 vCPUs and 14 GB of memory. Suitable for environments with up to 10 hosts or 100 virtual machines
Small	Deploys an appliance with 4 vCPUs and 21 GB of memory. Suitable for environments with up to 100 hosts or 1,000 virtual machines
Medium	Deploys an appliance with 8 vCPUs and 30 GB of memory. Suitable for environments with up to 400 hosts or 4,000 virtual machines
Large	Deploys an appliance with 16 vCPUs and 39 GB of memory. Suitable for environments with up to 1,000 hosts or 10,000 virtual machines
X-Large	Deploys an appliance with 24 vCPUs and 58 GB of memory. Suitable for environments with up to 2,500 hosts or 30,000 virtual machines. Suitable for environments with up to 2,500 hosts or 45,000 virtual machines with X-Large Storage.

10. Select the storage size for the new vCenter appliance 9.1 and click **Next**.

Important:
You must consider the storage size of the appliance that you are upgrading and the database size if external.

Storage Size Option	Tiny	Small	Medium	Large	X-Large
Default	Deploys an appliance with 619 GB of storage.	Deploys an appliance with 734 GB of storage.	Deploys an appliance with 933 GB of storage.	Deploys an appliance with 1383 GB of storage.	Deploys an appliance with 2308 GB of storage.
Large	Deploys an appliance with 2059 GB of storage.	Deploys an appliance with 2084 GB of storage.	Deploys an appliance with 2233 GB of storage.	Deploys an appliance with 2283 GB of storage.	Deploys an appliance with 2408 GB of storage.
X-Large	Deploys an appliance with 4319 GB of storage.	Deploys an appliance with 4344 GB of storage.	Deploys an appliance with 4493 GB of storage.	Deploys an appliance with 4543 GB of storage.	Deploys an appliance with 4668 GB of storage.

11. From the list of available datastores, select the location where all the virtual machine configuration files and virtual disks will be stored and, optionally, enable thin provisioning by selecting **Enable Thin Disk Mode**. NFS datastores are thin provisioned by default.
12. Configure the temporary network for communication between the vCenter appliance that you want to upgrade and the new vCenter appliance, and click **Next**.

Option	Action
Choose a network	Select the network to which to connect the new appliance temporarily. The networks displayed in the drop-down menu depend on the network settings of the target server. If you are deploying the appliance directly on an ESX host, non-ephemeral distributed virtual port groups are unsupported and are not displayed in the drop-down menu. **Important:** If you want to assign a temporary IPv4 address with DHCP allocation, you must select a network that is associated with a port group which accepts MAC address changes.
IP Address family	Select the version for the temporary IP address of the new appliance. Can be either IPv4 or IPv6.
Network type	Select the allocation method for the temporary IP address of the appliance. • **Static** The wizard prompts you to enter the temporary IP address, subnet mask or prefix length, default gateway, and DNS servers. • **DHCP** A DHCP server is used to allocate the temporary IP address. Select this option only if a DHCP server is available in your environment. Optionally, you can provide a temporary system name (FQDN) if a DDNS server is available in your environment.

13. On the Ready to complete stage 1 page, review the deployment settings for the new vCenter appliance and click **Finish** to start the OVA deployment process.
14. Wait for the OVA deployment process to finish and click **Continue** to proceed with stage 2 of the upgrade process to transfer the data from the old appliance and start the services of the new appliance.

    Note:
    If you exit the wizard by clicking **Close**, you must log in to the vCenter Management Interface of the newly deployed vCenter appliance to transfer the data from the old appliance and set up the services.

The newly deployed vCenter appliance 9.1 is running on the target server but is not configured.

Important:
The data from the old appliance is not transferred and the services of the new appliance are not started.

Stage 2 - Transfer the Data and Set up the Newly Deployed vCenter Appliance

When the OVA deployment finishes, you are redirected to stage 2 of the upgrade process to transfer the data from the old appliance and start the services of the newly deployed vCenter appliance 9.1.

- Verify that stage 1 has completed successfully.

- Verify that you have the root and vCenter Single Sign-On credentials for the source vCenter appliance.
- Ensure that port 5480 is accessible on the newly deployed appliance if you are accessing stage 2 using the vCenter Management Interface.

1. Launch stage 2.

Option	Description
Recommended. Continue directly in the GUI Installer.	1. On the stage 1 completion screen in the desktop installer, click **Continue**. 2. If an untrusted certificate warning appears for the target appliance on port `5480`, review the SHA-256 fingerprint and click **Accept**. 3. The installer window loads the stage 2 interface automatically.
Launch stage 2 manually from a web browser. **Use this option if you closed the GUI installer after stage 1 or you are resuming the upgrade from a different client machine.**	1. Open a web browser and navigate to `https://<target_vCenter_appliance_IP_FQDN>:5480`. 2. Accept the browser security certificate warning. 3. On the vCenter Management Interface landing page, click **Upgrade**. 4. Log in using the `root` user name and the `root` password that is configured for the target vCenter appliance during stage 1.

2. Review the introduction to stage 2 of the upgrade process and click **Next**.
3. Run and wait for the pre-upgrade checks to finish and read the pre-upgrade checks results if any.
   - If the pre-upgrade check results contain error messages, read the messages and click **Export Logs** to export and download the support bundle for troubleshooting.

     You cannot proceed with the upgrade until you have corrected the errors.

     Important:

     If you have provided incorrect vCenter Single Sign-On user name and password of the source appliance during stage 1, the pre-upgrade check fails with an authentication error.
   - If the pre-upgrade check results contain warning messages, read the messages and click **Close**.

     After you have verified that your system meets the requirements from the warning message, you can proceed with the upgrade.
4. Connect to the source appliance that you want to upgrade.
   a) Enter the information about the source vCenter appliance that you want to upgrade, and click **Connect to Source**.

Option	Action
Appliance FQDN or IP address	Enter the IP address or FQDN of the vCenter appliance that you want to upgrade.
Appliance HTTPS port	If the source appliance uses a custom HTTPS port, change the default value to that of the custom port. The default port value is 443. Custom port values are supported beginning with vCenter appliance version 6.5 Update 2. If you are upgrading from earlier versions, you cannot specify a custom port.

b) Enter the information about thevCenter Single Sign-On administrator and root user.

Option	Action
SSO user name	Enter the vCenter Single Sign-On administrator user name. **Important:** The user must be administrator@*your_domain_name*.
SSO password	Enter the password of the vCenter Single Sign-On administrator.
Appliance (OS) root password	Enter the password of the root user.

c) Enter the information about the source ESX host or vCenter instance on which resides the vCenter appliance that you want to upgrade and click **Next**.

Option	Description
Source server or host name	IP address or FQDN of the source ESX host or vCenter instance on which the vCenter appliance that you want to upgrade resides. **Note:** The source vCenter instance cannot be the vCenter appliance that you want to upgrade. In such cases, use the source ESX host.
HTTPS port	If the ESX host or vCenter instance uses a custom HTTPS port, change the default value. The default value is 443.
User name	User name of a user with administrative privileges on the ESX host or vCenter instance.
Password	Password of the user with administrative privileges on the ESX host or vCenter instance.

5. On the **Select migration data** page, choose the types of data that you want to transfer from the old appliance to the new vCenter 9.1 appliance and click **Next**.

Data Option	Description
Configuration	Imports only core inventory and configuration settings. Provides the fastest downtime and lowest storage requirements.
Configuration and Events/Tasks	Imports core configuration plus historical event and task records.
Configuration, Events, Tasks, and Performance Metrics	Imports all historical data, including performance metrics. Requires the longest transfer time and largest storage footprint.

A large amount of data requires more time to be transferred to the new appliance. For the minimum upgrade time and storage requirements for the new appliance, select to transfer only the configuration data.

6. Review the VMware Customer Experience Improvement Program (CEIP) page and choose if you want to join the program.

   For information about the CEIP, see the Configuring Customer Experience Improvement Program section in *vCenter and Host Management*.

7. On the Ready to complete page, review the upgrade settings, accept the backup acknowledgment, and click **Finish**.
8. Read the shutdown warning message confirming that the source vCenter appliance will be powered off once data export complete, sand click **OK**.
9. Wait for the data export, source node shutdown, network identity reassignment, data import, and service startup to finish, and click **OK** to go to the vCenter Getting Started page.

The vCenter appliance is upgraded. The old vCenter appliance is powered off and the new appliance starts.

- Verify Your vCenter Upgrade Is Successful.
- If the old vCenter appliance uses a non-ephemeral distributed virtual port group, to preserve the port group setting, you can manually connect the new appliance to the original non-ephemeral distributed virtual port group. For information about configuring virtual machine networking on a vSphere distributed switch, see *vSphere Networking*.
- You can configure high availability for the vCenter appliance. For information about providing vCenter appliance high availability, see *vSphere Availability*.

Upgrading vCenter in High Availability Environments

You can use the GUI installer to perform an interactive upgrade of a vCenter appliance in a high availability (HA) environment.

Prerequisites for Upgrading vCenter High Availability Environments

To ensure a successful upgrade of vCenter in a high availability (HA) environment, your environment must meet certain prerequisites before running the upgrade.

General Prerequisites

Ensure that your environment meets the prerequisites for upgrading vCenter appliance. See Prerequisites for Upgrading the vCenter Appliance.

High Availability Prerequisites

In addition to the prerequisites for upgrading a standard vCenter appliance, the vCenter High Availability (vCenter HA) upgrade has the following prerequisites.

- A vCenter HA cluster consists of three vCenter appliances that act as Active, Passive, and Witness nodes. The Active node must be configured as the vCenter HA node.
- The Active node is part of the vCenter HA cluster.
- All nodes must be present in the cluster.
- The vCenter HA cluster must be in a healthy state.
- The vCenter HA cluster must be in enabled mode.
- The host that has the vCenter virtual machine (VM) must be managed by a container vCenter. It must not be standalone.
- The target vCenter must have the same placement as the source vCenter.
- vCenter HA cannot be set up on a vCenter that has disks on more than one datastore.

To learn more about vCenter HA configuration, see High Availability.

Upgrade a vCenter Appliance HA Cluster by Using the GUI

You can use the GUI installer to perform an interactive upgrade of a vCenter HA cluster of version 9.0 or later to vCenter appliance 9.1. You must run the GUI upgrade from a Windows, Linux, or Macintosh computer that is in the same network as the appliance that you want to upgrade.

- Ensure that your environment meets the prerequisites for upgrading a vCenter HA cluster. See Prerequisites for Upgrading vCenter High Availability Environments.
- See Required Information for Upgrading a vCenter Appliance 8.0 and Later to Version 9.1.

A vCenter HA cluster consists of three vCenter appliances that act as Active, Passive, and Witness nodes. The Active vCenter HA node is upgraded using a migration-based upgrade while preserving the existing configuration.

Stage 1 - Deploy the OVA File of the New vCenter High Availability Cluster

With stage 1 of the upgrade process, you deploy the OVA file of the new vCenter appliance 9.1.

Ensure that your environment meets the prerequisites for upgrading a vCenter HA cluster. See Prerequisites for Upgrading vCenter High Availability Environments.

1. In the vCenter installer, navigate to the `vcsa-ui-installer` directory, go to the subdirectory for your operating system, and run the installer executable file.
   - For Windows OS, go to the `win32` subdirectory, and run the `installer.exe` file.
   - For Linux OS, go to the `lin64` subdirectory, and run the `installer` file.
   - For Mac OS, go to the `mac` subdirectory, and run the `Installer.app` file.
2. On the Home page, click **Upgrade**.
3. Review the Introduction page to understand the upgrade process and click **Next**.
4. Read and accept the license agreement, and click **Next**.
5. Connect to the source appliance that you want to upgrade. This appliance is the Active vCenter HA node.
   a) Enter the information about the source vCenter appliance that you want to upgrade, and click **Connect to Source**.

Option	Action
Appliance FQDN or IP address	Enter the IP address or FQDN of the Active vCenter HA node that you want to upgrade.
Appliance HTTPS port	The default value (443) is displayed and cannot be edited.

   b) Enter the information about the vCenter Single Sign-On administrator and root user.

Option	Action
SSO user name	Enter the vCenter Single Sign-On administrator user name. **Important:** The user must be administrator@*your_domain_name*.
SSO password	Enter the password of the vCenter Single Sign-On administrator.
Appliance (OS) root password	Enter the password of the root user.

   c) Enter the information about the source vCenter instance on which resides the vCenter appliance that you want to upgrade and click **Next**.

Option	Description
Source server or host name	IP address or FQDN of the Active node. The Active node must be configured as the vCenter HA node.
HTTPS port	If the vCenter instance uses a custom HTTPS port, change the default value. The default value is 443.
User name	User name of a user with administrative privileges on the ESX host or vCenter instance.
Password	Password of the user with administrative privileges on the ESX host or vCenter instance.

6. Verify that the certificate warning displays the SHA1 thumbprints of the SSL certificates that are installed on the source appliance and its source server, and click **Yes** to accept the certificate thumbprints.
7. If vCenter HA is successfully detected, the target appliance is set to the manager of the source appliance. Click OK.
   The appliance deployment target information is populated.

8. Connect to the target server on which you want to deploy the new vCenter appliance.

Option	Steps
You can connect to an ESX host on which to deploy the new appliance.	1. Enter the FQDN or IP address of the ESX host. 2. Enter the HTTPS port of the ESX host. 3. Enter the user name and password of a user with administrative privileges on the ESX host, for example, the root user. 4. Click **Next**. 5. Accept the certificate warning, if any, by clicking **Yes**.
You can connect to a vCenter instance and browse the inventory to select an ESX host or DRS cluster on which to deploy the new appliance. **Note:** The target server cannot be the vCenter appliance that you want to upgrade. In such cases, use an ESX host as a target server.	1. Enter the FQDN or IP address of the vCenter instance. 2. Enter the HTTPS port of the vCenter instance. 3. Enter the user name and password of a vCenter Single Sign-On user with administrative privileges on the vCenter instance, for example, the administrator@*your_domain_name* user. 4. Click **Next**. 5. Accept the certificate warning, if any, by clicking **Yes**. 6. Select the data center or data center folder that contains the ESX host or DRS cluster on which you want to deploy the new appliance, and click **Next** **Note:** You must select a data center or data center folder that contains at least one ESX host that is not in lockdown or maintenance mode. 7. Select the ESX host or DRS cluster on which you want to deploy the new appliance, and click **Next**.

9. On the Set up target appliance VM page, enter a name for the new vCenter appliance, set the password for the root user, and click **Next**.

   The appliance name must not contain a percent sign (%), backslash (\), or forward slash (/) and must be no more than 80 characters in length.

   The password must contain only lower ASCII characters without spaces, at least eight characters, a number, uppercase and lowercase letters, and a special character, for example, an exclamation mark (!), hash key (#), at sign (@), or brackets (()).

   Note:
   The root password of the old appliance is not transferred to the new upgraded appliance.

10. Select the deployment size for the new vCenter appliance for your vSphere inventory.

Deployment Profile	Description
Tiny	Deploys an appliance with 2 vCPUs and 14 GB of memory. Suitable for environments with up to 10 hosts or 100 virtual machines
Small	Deploys an appliance with 4 vCPUs and 21 GB of memory. Suitable for environments with up to 100 hosts or 1,000 virtual machines
Medium	Deploys an appliance with 8 vCPUs and 30 GB of memory. Suitable for environments with up to 400 hosts or 4,000 virtual machines
Large	Deploys an appliance with 16 vCPUs and 39 GB of memory. Suitable for environments with up to 1,000 hosts or 10,000 virtual machines
X-Large	Deploys an appliance with 24 vCPUs and 58 GB of memory.

Deployment Profile	Description
	Suitable for environments with up to 2,500 hosts or 30,000 virtual machines. Suitable for environments with up to 2,500 hosts or 45,000 virtual machines with X-Large Storage.

11. Select the storage size for the new vCenter appliance, and click **Next**.

    Important:
    You must consider the storage size of the appliance that you are upgrading and the database size if external.

Storage Size Option	Tiny	Small	Medium	Large	X-Large
Default	Deploys an appliance with 619 GB of storage.	Deploys an appliance with 734 GB of storage.	Deploys an appliance with 933 GB of storage.	Deploys an appliance with 1383 GB of storage.	Deploys an appliance with 2308 GB of storage.
Large	Deploys an appliance with 2059 GB of storage.	Deploys an appliance with 2084 GB of storage.	Deploys an appliance with 2233 GB of storage.	Deploys an appliance with 2283 GB of storage.	Deploys an appliance with 2408 GB of storage.
X-Large	Deploys an appliance with 4319 GB of storage.	Deploys an appliance with 4344 GB of storage.	Deploys an appliance with 4493 GB of storage.	Deploys an appliance with 4543 GB of storage.	Deploys an appliance with 4668 GB of storage.

12. From the list of available datastores, select the location to store the virtual machine (VM) configuration files and virtual disks, and, optionally, enable thin provisioning by selecting **Enable Thin Disk Mode**. NFS datastores are thin provisioned by default.

    Note:

    vCenter HA cannot be set up on a vCenter that has disks on more than one datastore.

13. Configure the temporary network for communication between the vCenter appliance that you want to upgrade and the new vCenter appliance, and click **Next**.

Option	Action
Choose a network	Select the network to which to connect the new appliance temporarily. The networks displayed in the drop-down menu depend on the network settings of the target server. If you are deploying the appliance directly on an ESX host, non-ephemeral distributed virtual port groups are unsupported and are not displayed in the drop-down menu. **Important:** If you want to assign a temporary IPv4 address with DHCP allocation, you must select a network that is associated with a port group which accepts MAC address changes.
IP Address family	Select the version for the temporary IP address of the new appliance. Can be either IPv4 or IPv6.

Option	Action
Network type	Select the allocation method for the temporary IP address of the appliance. • **Static** The wizard prompts you to enter the temporary IP address, subnet mask or prefix length, default gateway, and DNS servers. • **DHCP** A DHCP server is used to allocate the temporary IP address. Select this option only if a DHCP server is available in your environment. Optionally, you can provide a temporary system name (FQDN) if a DDNS server is available in your environment.

14. On the Ready to complete stage 1 page, review the deployment settings for the new vCenter appliance and click **Finish** to start the OVA deployment process.
15. Wait for the OVA deployment process to finish and click **Continue** to proceed with stage 2 of the upgrade process to transfer the data from the old appliance and start the services of the new appliance.

    Note:
    If you exit the wizard by clicking **Close**, you must log in to the vCenter Management Interface of the newly deployed vCenter appliance to transfer the data from the old appliance and set up the services.

The newly deployed target vCenter appliance 9.1 is running on the target server but is not configured.

Important:
The data from the source vCenter is not transferred and the services of the target appliance are not started. Transfer the data from the old appliance and start the services of the newly deployed vCenter appliance. See Stage 2 - Transfer Data and Set-Up the Newly Deployed vCenter High Availability Cluster.

Stage 2 - Transfer Data and Set-Up the Newly Deployed vCenter High Availability Cluster

When the OVA deployment finishes, you are redirected to stage 2 of the upgrade process to transfer the data from the old appliance and start the services of the newly deployed vCenter appliance. When the deployment finishes, vCenter has high availability protection.

- Verify that stage 1 has completed successfully.
- Verify that you have the root user password and vCenter Single Sign-On administrator credentials for the source vCenter appliance.
- Verify that you have administrative credentials for the ESX host or vCenter on which the source vCenter HA Active node resides.
- Verify that port `5480` and port `443` are accessible between your deployment client machine, the source appliance, and the new target appliance.
- Verify that you have performed a full file-based backup or VM snapshot of the source vCenter appliance before proceeding with stage 2.

1. Launch stage 2.

Option	Description
Recommended. Continue directly in the GUI Installer.	1. On the stage 1 completion screen in the desktop installer, click **Continue**. 2. If an untrusted certificate warning appears for the target appliance on port `5480`, review the SHA-256 fingerprint and click **Accept**. 3. The installer window loads the stage 2 interface automatically.
Launch stage 2 manually from a web browser.	1. Open a web browser and navigate to `https://<target_vCenter_appliance_IP_FQDN>:5480`. 2. Accept the browser security certificate warning.

Option	Description
Use this option if you closed the GUI installer after stage 1 or you are resuming the upgrade from a different client machine.	3. On the vCenter Management Interface landing page, click **Upgrade**. 4. Log in using the `root` user name and the `root` password that is configured for the target vCenter appliance during stage 1.

2. Review the introduction to stage 2 of the upgrade process and click **Next**.
3. Run and wait for the pre-upgrade checks to finish and read the pre-upgrade checks results if any.
   - If the pre-upgrade check results contain error messages, read the messages and click **Export Logs** to export and download the support bundle for troubleshooting.

     You cannot proceed with the upgrade until you have corrected the errors.

     Important:

     If you have provided incorrect vCenter Single Sign-On user name and password of the source appliance during stage 1, the pre-upgrade check fails with an authentication error.
   - If the pre-upgrade check results contain warning messages, read the messages and click **Close**.

     After you have verified that your system meets the requirements from the warning message, you can proceed with the upgrade.
4. Enter the connection and credential details for the source vCenter HA Active node and its hosting ESX host or vCenter and click **Next**.

Field	Action/Description
Appliance FQDN or IP address	Enter the FQDN or temporary IP address of the source vCenter Active node.
Appliance HTTPS port	Enter the HTTPS port of the source appliance. Default value is `443`.
vCenter Single Sign-On user name	Enter the vCenter Single Sign-On administrator account (`administrator@vsphere.local`).
vCenter Single Sign-On password	Enter the password for the vCenter Single Sign-On administrator account.
Appliance (OS) root password	Enter the `root` user password for the source appliance.
Source host or server name	Enter the FQDN or IP address of the ESX host or vCenter hosting the source Active VM.
Source Hhst HTTPS port	Enter the HTTPS port of the hosting ESX host or vCenter. Default value is `443`.
Source host user name	Enter an administrative user account for the hosting server (`root` for ESX host).
Source host password	Enter the password for the administrative user account on the hosting server.

5. On the **Select migration data** page, choose the types of data that you want to transfer from the old appliance to the new vCenter 9.1 appliance and click **Next**.

Data Option	Description
Configuration	Imports only core inventory and configuration settings. Provides the fastest downtime and lowest storage requirements.
Configuration and Events/Tasks	Imports core configuration plus historical event and task records.
Configuration, Events, Tasks, and Performance Metrics	Imports all historical data, including performance metrics. Requires the longest transfer time and largest storage footprint.

A large amount of data requires more time to be transferred to the new appliance. For the minimum upgrade time and storage requirements for the new appliance, select to transfer only the configuration data.

6. Select whether to join the VMware Customer Experience Improvement Program (CEIP) and click **Next**.
7. On the Ready to complete page, review the upgrade settings, accept the backup acknowledgment, and click **Finish**.
8. Read the shutdown warning message confirming that the source vCenter appliance will be powered off once data export complete, sand click **OK**.
9. Wait for the data export, source node shutdown, network identity reassignment, data import, and service startup to finish, and click **OK** to go to the vCenter Getting Started page.

The vCenter appliance is upgraded. The old vCenter appliance is powered off and the new appliance starts.

After the Active node is upgraded, a new Passive and Witness node is created using a clone operation. These nodes are created automatically for Auto Deployment. For Manual Deployment, nodes are not created automatically. You must clone the Passive and Witness VMs and set the cluster mode to **enabled**.

When the deployment finishes, vCenter has high availability protection. You can click **Edit** to enter Maintenance Mode, Deactivate, or Remove vCenter HA. You can also initiate vCenter HA failover.

- Verify Your vCenter Upgrade Is Successful.
- If the old vCenter appliance uses a non-ephemeral distributed virtual port group, to preserve the port group setting, you can manually connect the new appliance to the original non-ephemeral distributed virtual port group. For information about configuring virtual machine networking on a vSphere distributed switch, see *vSphere Networking*.
- Upgrade all vCenter instances in the vCenter Single Sign-On domain.
  You can configure high availability for the vCenter appliance. For information about providing vCenter appliance high availability, see *vSphere Availability*.

CLI Upgrade of the vCenter Appliance

You can use the CLI installer to perform an unattended upgrade of a vCenter appliance on an ESX host or vCenter instance.

The CLI upgrade process includes downloading the vCenter appliance installer on a network virtual machine or physical server from which you want to perform the upgrade, preparing a JSON configuration file with the upgrade information, and running the upgrade command.

> **Important:**
> The user name that you use to log in to the machine from which you want to run the CLI upgrade, the path to the vCenter appliance ISO file, the path to your JSON configuration file, and the string values in your JSON configuration file, including the passwords, must contain only ASCII characters. Extended ASCII and non-ASCII characters are unsupported.

The vCenter appliance ISO file contains templates of JSON files that contain the minimum configuration parameters that are required for upgrading a vCenter appliance. For information about preparing JSON templates for CLI upgrade of the vCenter appliance, see Prepare Your JSON Configuration File for CLI Upgrade.

Prepare Your JSON Configuration File for CLI Upgrade

Before you run the CLI command to upgrade a vCenter appliance, you must prepare a JSON file with configuration parameters and their values for your upgrade specification.

- You must be familiar with the JSON syntax.
- Download and Mount the vCenter Installer.

The vCenter installer contains JSON templates for all upgrade types. For information about the templates, see JSON Templates for CLI Upgrade of the vCenter Appliance.

You can upgrade an appliance with minimum configurations by setting values to the configuration parameters in the JSON template for your specification. You can edit the preset values, remove configuration parameters, and add configuration parameters for custom configurations.

For a complete list of the configuration parameters and their descriptions, navigate to the installer subdirectory for your operating system and run the `vcsa-deploy upgrade --template-help` command or see Upgrade Configuration Parameters for CLI Upgrade of vCenter Appliance .

1. In the vCenter appliance installer, navigate to the `vcsa-cli-installer` directory, and open the `templates` subfolder.
2. Copy the upgrade templates from the `upgrade` subfolder to your workspace.

   Important:
   The path to the JSON configuration files must contain only ASCII characters. Extended ASCII and non-ASCII characters are unsupported.
3. Open the template file for your use case in a text editor.

   To ensure the correct syntax of your JSON configuration file, use a JSON editor.
4. Fill in the values for the required configuration parameters and, optionally, enter additional parameters and their values.
   For example, if you want to use an IPv4 DHCP assignment for the temporary network of the new appliance, in the `temporary_network` subsection of the template, change the value of the `mode` parameter to `dhcp` and remove the default configuration parameters that are for a static assignment.

   ```
   "temporary_network": {
       "ip_family": "ipv4",
       "mode": "dhcp"
   },
   ```

   Important:
   The string values, including the passwords, must contain only ASCII characters. Extended ASCII and non-ASCII characters are unsupported.

   To set a value that contains a backslash (\) or quotation mark (") character, you must precede the character with the backslash (\) character. For example, `"password":"my\"password"` sets the password my"password, `"image":"G:\\vcsa\\VMware-vCenter-Server-Appliance-9.1.X.XXXX-YYYYYYY_OVF10.ova"` sets the path `G:\vcsa\VMware-vCenter-Server-Appliance-9.1.x.XXXX-YYYYYYY_OVF10.ova`.

   The Boolean values must contain only lowercase characters, that is, a value can be either `true` or `false`. For example, `"ssh_enable":false`.
5. Optional: Use a JSON editor of your choice to validate the JSON file.
6. Save in UTF-8 format and close the file.

You can create and save additional templates if needed for your upgrade specification.

JSON Templates for CLI Upgrade of the vCenter Appliance

The vCenter appliance installer contains JSON templates that are located in the `vcsa-cli-installer/templates` directory. In the `upgrade` subfolder, you can find the JSON templates with the minimum configuration parameters for all upgrade types.

For each upgrade type, there is one template for deploying the new appliance on an ESX host and another template for deploying the new appliance on a vCenter instance.

Table 53: Upgrade JSON Templates Included in the vCenter Appliance Installer

Location	Template	Description
`vcsa-cli-installer\templates\upgrade\vcsa8.0`	`embedded_vCSA_on_ESXi.json`	Contains the minimum configuration parameters that are required for upgrade of a vCenter appliance 9.0 to vCenter appliance 9.1 on an ESX host.
	`embedded_vCSA_on_VC.json`	Contains the minimum configuration parameters that are required for upgrade of a vCenter appliance 9.0 to vCenter appliance 9.1 on a vCenter instance.

Upgrade Configuration Parameters for CLI Upgrade of vCenter Appliance

When you prepare your JSON configuration files for CLI upgrade, you must set parameters and values to provide input data for the upgrade of a vCenter appliance.

Sections and Subsections of Configuration Parameters in the JSON Upgrade Files

The configuration parameters in the JSON configuration files for CLI upgrade are organized in sections and subsections.

Table 54: Sections and Subsections of Configuration Parameters in the JSON Upgrade Files

Section	Subsection	Description
`new_vcsa` - describes the new appliance that you want to deploy.	`esxi`	Use only if you want to deploy the new appliance directly on an ESX host. Contains the configuration parameters that describe the target ESX host. See Table 55: Configuration Parameters in the new_vcsa Section, esxi Subsection. **Note:** You must fill in either this subsection or the `vc` subsection.
	`vc`	Use only if you want to deploy the new appliance on the inventory of a vCenter instance. Contains the configuration parameters that describe the target ESX host or DRS cluster from the vCenter inventory. See Table 56: Configuration Parameters in the new_vcsa Section, vc Subsection. **Note:** You must fill in either this subsection or the `esxi` subsection. The target vCenter instance cannot be the vCenter appliance that you want to upgrade. In such cases, use the `esxi` subsection.
	`appliance`	Contains the configuration parameters that describe the new appliance. See Table 57: Configuration Parameters in the new_vcsa Section, appliance Subsection
	`os`	Contains only the `ssh_enable` configuration parameter to set the SSH administrator login to the new appliance.
	`ovftool_arguments`	Optional. Use this subsection for adding arbitrary arguments and their values to the OVF Tool command that the installer generates. **Important:** The vCenter appliance installer does not validate the configuration parameters in the `ovftool_arguments` subsection. If you set arguments that the OVF Tool does not recognize, the deployment might fail.
	`temporary_network`	Contains the configuration parameters that describe the temporary network settings for the new appliance. See Table 58: Configuration Parameters in the new_vcsa Section, temporary_network Subsection
	`user_options`	Contains only the `vcdb_migrateSet` configuration parameter to set the types of data that you want to transfer from the old appliance to the new appliance. See Table 59: Configuration Parameters in the new_vcsa Section, user_options Subsection
`source_vc` - describes the existing appliance that you want to upgrade.	`managing_esxi_or_vc`	Contains the configuration parameters that describe the source ESX host or vCenter appliance instance on which resides the appliance that you want to upgrade. See Table 61: Configuration Parameters in the source_vc Section, managing_esxi_or_vc Subsection.
	`vc_vcsa`	Contains the configuration parameters that describe the source appliance that you want to upgrade. See Table 62: Configuration Parameters in the source_vc Section, vc_vcsa Subsection.

Section	Subsection	Description
`ceip` - describes joining the VMware Customer Experience Improvement Program (CEIP).	`settings`	Contains only the `ceip_enabled` configuration parameter to join or not to join the VMware Customer Experience Improvement Program (CEIP). See Table 63: Configuration Parameters in the ceip Section, settings Subsection. **Note:** If the `ceip_enabled` configuration parameter is set to `true`, you must run the CLI deployment command with the `--acknowledge-ceip` argument. For information about the CEIP, see the Configuring Customer Experience Improvement Program section in *vCenter and Host Management*.

Important:
The string values, including the passwords, must contain only ASCII characters. Extended ASCII and non-ASCII characters are unsupported.

To set a value that contains a backslash (\) or quotation mark (") character, you must precede the character with the backslash (\) character. For example, `"password":"my\"password"` sets the password my"password, `"image":"G:\\vcsa\\VMware-vCenter-Server-Appliance-9.1.x.XXXX-YYYYYYY_OVF10.ova"` sets the path `G:\vcsa\VMware-vCenter-Server-Appliance-9.1.x.XXXX-YYYYYYY_OVF10.ova`.

The Boolean values must contain only lowercase characters. Can be either `true` or `false`. For example, `"ssh_enable":false`.

Configuration Parameters in the `new_vcsa` Section

Table 55: Configuration Parameters in the `new_vcsa` Section, `esxi` Subsection

Name	Type	Description
`hostname`	string	The IP address or FQDN of the target ESX host on which you want to deploy the new appliance.
`username`	string	A user name with administrative privileges on the target ESX host, for example, root.
`password`	string	The password of the user with administrative privileges on the target ESX host.
`deployment_network`	string	The name of the network to which to connect the new appliance. The network must be part of the target ESX host or vCenter appliance instance (as identified by the `managing_esxi_or_vc` configuration parameter) network configuration. **Note:** The network must be accessible from the source ESX host or vCenter appliance instance (as identified by the `managing_esxi_or_vc` configuration parameter) on which resides the appliance that you want to upgrade. The network must be also accessible from the client machine from which you are performing the upgrade. Ignored if the target ESX host has only one network.
`datastore`	string	The name of the datastore on which to store the virtual machine configuration files and virtual disks of the new appliance. The datastore must be available to the target ESX host. **Note:** The datastore must have at least 25 GB of free space.
`port`	integer	The HTTPS reverse proxy port of the target ESX host. The default port is 443. Use only if the target ESX host uses a custom HTTPS reverse proxy port.

Name	Type	Description

ssl_certificate_verification	string	The CLI verifies that a server's security certificate is signed by a Certificate Authority (CA), and establishes a secure connection. If the certificate is self-signed, the CLI stops the upgrade unless you specify one of the following SSL certificate configuration options:
		Specify the Secure Hash Algorithm 1 (SHA-1) certificate thumbprint. A certificate thumbprint is a hexadecimal string that uniquely identifies a certificate. The thumbprint is calculated from the content of the certificate using a thumbprint algorithm.
		`"thumbprint": "certificate SHA-1 thumbprint"`
		Set verification_mode to NONE.
		`"verification_mode": "NONE"`
		If you are connecting to a server with a self-signed certificate, and fail to either specify the SHA-1 certificate thumbprint or set the verification mode to NONE, the CLI displays the server's self-signed certificate thumbprint, and prompts you to accept or reject the certificate thumbprint.
		You may also specify that the CLI ignore the self-signed using the vcsa-deploy upgrade command parameter --no-ssl-certificate-validation. See Syntax of the CLI Upgrade Command .

Table 56: Configuration Parameters in the new_vcsa Section, vc Subsection

Name	Type	Description
hostname	string	The IP address or FQDN of the target vCenter instance on which you want to deploy the new appliance.
username	string	vCenter Single Sign-On administrator user name on the target vCenter instance, for example, administrator@vsphere.local.
password	string	The password of the vCenter Single Sign-On administrator user on the target vCenter instance.
deployment_network	string	The name of the network to which to connect the new appliance. The network must part of the target ESX host or DRS cluster network configuration. **Note:** The network must be accessible from the source ESX host on which resides the appliance that you want to upgrade. The network must be also accessible from the client machine from which you are performing the upgrade. Ignored if the target ESX host or DRS cluster has only one network.

datacenter	array	The vCenter data center that contains the target ESX host or DRS cluster on which you want to deploy the new appliance.
		If the data center is located in a folder or a structure of folders, specify the as a comma-separated list of strings. For example,
		`["parent_folder", "child_folder", "datacenter_name"]`
		If there is no folder path on the data center, then use only the data center name. For example,
		`["datacenter_name"]`
		or
		`"datacenter_name"`
		Note:
		The value is case-sensitive.

datastore	string	The name of the datastore that you want to store all virtual machine configuration files and virtual disks of the new appliance. **Note:** The datastore must be available to the target ESX host or DRS cluster. The datastore must have at least 25 GB of free space.

Name	Type	Description
`port`	integer	The HTTPS reverse proxy port of the target vCenter instance. The default port is 443. Use only if the target vCenter instance uses a custom HTTPS reverse proxy port.

`target`	array	The target cluster, ESX host, or resource pool on which you want to deploy the new appliance. This is the target you specified with the `datacenter` parameter. This path must end with a cluster name, ESXi hostname, or resource pool name.
		
		Important:
		You must provide the name that is displayed in the vCenter inventory. For example, if the name of the target ESX host is an IP address in the vCenter inventory, you cannot provide an FQDN.
		
		Note:
		All values are case-sensitive.
		If you want the deployed appliance to be listed in a different location within the data center's hierarchy, use the `vm_folder` parameter described later in this section.
		If the target cluster, ESX host, or resource pool is located in a folder or a structure of folders, specify the value as a comma-separated list of strings. For example,
		`["parent_folder", "child_folder", "esxi-host.domain.com"]`
		If the target ESX host is part of a cluster, specify the path as a comma-separated list of strings. For example,
		`["cluster_name","esxi-host.domain.com"]`
		
		If you are deploying to a resource pool, include the label `Resources` before the resource pool name. For example:
		`["cluster_name", "Resources", "resource_pool_name"]`
		
		Note:
		Pre-checks verify only the memory of the resource pool.

`vm_folder`	string	Optional. The name of the virtual machine (VM) folder to which to add the new appliance.

Table 57: Configuration Parameters in the `new_vcsa` Section, `appliance` Subsection

Name	Type	Description
`thin_disk_mode`	Boolean	Set to `true` to deploy the new appliance with thin virtual disks.
`deployment_option`	string	The size for the new appliance. • Set to `tiny` if you want to deploy a vCenter appliance for up to 10 hosts and 100 virtual machines with the default storage size. Deploys an appliance with 2 CPUs, 10 GB of memory, and 300 GB of storage. • Set to `tiny-lstorage` if you want to deploy a vCenter appliance for up to 10 hosts and 100 virtual machines with the large storage size. Deploys an appliance with 2 CPUs, 10 GB of memory, and 825 GB of storage. • Set to `tiny-xlstorage` if you want to deploy a vCenter appliance for up to 10 hosts and 100 virtual machines with the x-large storage size. Deploys an appliance with 2 CPUs, 10 GB of memory, and 1700 GB of storage. • Set to `small` if you want to deploy a vCenter appliance for up to 100 hosts and 1,000 virtual machines with the default storage size. Deploys an appliance with 4 CPUs, 16 GB of memory, and 340 GB of storage. • Set to `small-lstorage` if you want to deploy a vCenter appliance for up to 100 hosts and 1,000 virtual machines with the large storage size. Deploys an appliance with 4 CPUs, 16 GB of memory, and 870 GB of storage. • Set to `small-xlstorage` if you want to deploy a vCenter appliance for up to 100 hosts and 1,000 virtual machines with the x-large storage size. Deploys an appliance with 4 CPUs, 16 GB of memory, and 1750 GB of storage. • Set to `medium` if you want to deploy a vCenter appliance for up to 400 hosts and 4,000 virtual machines with the default storage size. Deploys an appliance with 8 CPUs, 24 GB of memory, and 525 GB of storage. • Set to `medium-lstorage` if you want to deploy a vCenter appliance for up to 400 hosts and 4,000 virtual machines with the large storage size. Deploys an appliance with 8 CPUs, 24 GB of memory, and 1025 GB of storage. • Set to `medium-xlstorage` if you want to deploy a vCenter appliance for up to 400 hosts and 4,000 virtual machines with the x-large storage size. Deploys an appliance with 8 CPUs, 24 GB of memory, and 1905 GB of storage. • Set to `large` if you want to deploy a vCenter appliance for up to 1,000 hosts and 10,000 virtual machines with the default storage size. Deploys an appliance with 16 CPUs, 32 GB of memory, and 740 GB of storage. • Set to `large-lstorage` if you want to deploy a vCenter appliance for up to 1,000 hosts and 10,000 virtual machines with the large storage size. Deploys an appliance with 16 CPUs, 32 GB of memory, and 1090 GB of storage. • Set to `large-xlstorage` if you want to deploy a vCenter appliance for up to 1,000 hosts and 10,000 virtual machines with the x-large storage size. Deploys an appliance with 16 CPUs, 32 GB of memory, and 1970 GB of storage. • Set to `xlarge` if you want to deploy a vCenter appliance for up to 2,000 hosts and 35,000 virtual machines with the default storage size. Deploys an appliance with 24 CPUs, 48 GB of memory, and 1180 GB of storage. • Set to `xlarge-lstorage` if you want to deploy a vCenter appliance for up to 2,000 hosts and 35,000 virtual machines with the large storage size. Deploys an appliance with 24 CPUs, 48 GB of memory, and 1230 GB of storage. • Set to `xlarge-xlstorage` if you want to deploy a vCenter appliance for up to 2,000 hosts and 35,000 virtual machines with the x-large storage size. Deploys an appliance with 24 CPUs, 48 GB of memory, and 2110 GB of storage. • Set to `management-tiny` if you want to deploy a vCenter appliance for up to 10 hosts and 100 virtual machines with the default storage size. Deploys an appliance with 2 CPUs, 10 GB of memory, and 300 GB of storage.
`image`	string	Optional. A local file path or URL to the vCenter appliance installation package. By default the installer uses the installation package that is included in the ISO file, in the `vcsa` folder.

Name	Type	Description
name	string	The VM name for the new appliance. Must contain only ASCII characters except a percent sign (%), backslash (\), or forward slash (/) and must be no more than 80 characters in length.
ovftool_path	string	Optional. A local file path to the OVF Tool executable file. By default the installer uses the OVF Tool instance that is included in the ISO file, in the vcsa/ovftool folder.

Table 58: Configuration Parameters in the `new_vcsa` Section, `temporary_network` Subsection

Name	Type	Description
ip_family	string	IP version for the temporary network of the new appliance. Set to ipv4 or ipv6.
mode	string	IP assignment for the temporary network of the new appliance. Set to static or dhcp.
ip	string	Temporary IP address for the new appliance. Required only if you use a static assignment, that is, if you set the mode parameter to static. You must set an IPv4 or IPv6 address that corresponds to the temporary network IP version, that is, to the value of the ip.family parameter. An IPv4 address must comply with the RFC 790 guidelines. An IPv6 address must comply with the RFC 2373 guidelines.

dns_servers	string or array	IP addresses of one or more DNS servers for the temporary network of the new appliance.
		To set more than one DNS server, use a comma-separated list of strings or a comma-separated list as a single string to provide the path. For example,
		`["x.y.z.a", "x.y.z.b"]`
		or
		`"x.y.z.a, x.y.z.b"`
		Required only if you use static network mode for the temporary IP address allocation, that is, if you set the mode parameter to static.

prefix	string	Network prefix length for the temporary network of the new appliance. Use only if the mode parameter is set to static. Remove if the mode parameter is set to dhcp. The network prefix length is the number of bits that are set in the subnet mask. For example, if the subnet mask is 255.255.255.0, there are 24 bits in the binary version of the prefix length, so the network prefix length is 24. For IPv4 version, the value must be between 0 and 32. For IPv6 version, the value must be between 0 and 128.
gateway	string	IP address of the default gateway for the temporary network of the new appliance. For IPv6 version, the value can be default.

Table 59: Configuration Parameters in the `new_vcsa` Section, `user_options` Subsection

Name	Type	Description
`vcdb_migrateSet`	string	Select the types of data to migrate from the old appliance to the new appliance. Data is copied from the source vCenter to the target server. The original source of the data remains unchanged. • Set to `core` if you want to transfer only the configuration data. This option provides the fastest data migration, keeping system downtime to a minimum. • Set to `core_events_tasks` if you want to transfer the configuration and historical data (events and tasks) immediately. vCenter will not start until all data has been migrated from the source vCenter appliance. • Set to `all` if you want to transfer the configuration, historical, and performance metrics data immediately. vCenter will not start until all data has been migrated from the source vCenter for Windows. This option transfers the largest amount of data, and requires more downtime than other data migration options. **Note:** To minimize the upgrade time and the amount of storage required for the new vCenter appliance, use the `core` value. For more information on the types of data you can transfer from your existing vCenter to the new, upgraded vCenter, see Transferring Data from an Existing vCenter Appliance.

Table 60: Configuration Parameters in the `new_vcsa` Section, `sso` Subsection

Name	Type	Description
`first_instance`	string	Set `first_instance` to `true` if this is the first converge upgrade operation in your vCenter SSO domain, or if you do not want to set the replication partner for this node. If you want to set the replication partner for this node, set `first_instance` to `false` and provide the value of the `replication_partner_hostname` as the FQDN of a previously converged node which is currently in an embedded vCenter topology.
`replication_partner_hostname`	string	Host name of the replication partner. Remove if it is the `first_instance`.

Configuration Parameters in the `source_vc` Section

Table 61: Configuration Parameters in the `source_vc` Section, `managing_esxi_or_vc` Subsection

Name	Type	Description
`hostname`	string	The IP address or FQDN of the source ESX or vCenter host on which resides the appliance that you want to upgrade.
`username`	string	A user name with administrative privileges on the source ESX host, for example, root.
`password`	string	The password of the user with administrative privileges on the source ESX host.
`port`	integer	The HTTPS reverse proxy port of the source ESX host. The default port is 443. Use only if the source ESX host uses a custom HTTPS reverse proxy port.

Table 62: Configuration Parameters in the `source_vc` Section, `vc_vcsa` Subsection

Name	Type	Description
`hostname`	string	The IP address or FQDN of the source appliance that you want to upgrade.
`username`	string	vCenter Single Sign-On administrator user on the source appliance, for example administrator@vsphere.local. **Important:** The user must be administrator@*`your_domain_name`*.
`password`	string	The password of the vCenter Single Sign-On administrator user on the source appliance.
`root_password`	string	The password for the root user of the operating system of the source appliance.
`export_dir`	string	Directory to export source configuration and data.

Configuration Parameters in the `ceip` Section

Table 63: Configuration Parameters in the `ceip` Section, `settings` Subsection

Name	Type	Description
`ceip_enabled`	Boolean	Set to `true` to join the CEIP for the new upgraded appliance.

Upgrade a vCenter Appliance by Using the CLI

You can use the CLI installer to perform an unattended upgrade of a vCenter appliance. You must run the CLI upgrade from a Windows, Linux, or Mac machine that is in the same network as the appliance that you want to upgrade.

- See Prerequisites for Upgrading the vCenter Appliance.
- Prepare Your JSON Configuration File for CLI Upgrade.
- Review the arguments for running the CLI upgrade. See Syntax of the CLI Upgrade Command.
- Verify that the user name with which you are logged in to your machine, the path to the vCenter appliance installer, the path to your JSON configuration file, and the string values in your JSON configuration file contain only ASCII characters. Extended ASCII and non-ASCII characters are not supported.

1. Navigate to the `vcsa-cli-installer` subdirectory for your operating system.
   - If you are running the upgrade on Windows, navigate to the `vcsa-cli-installer\win32` directory.
   - If you are running the upgrade on Linux, navigate to the `vcsa-cli-installer/lin64` directory.
   - If you are running the upgrade on Mac, navigate to the `vcsa-cli-installer/mac` directory.
2. Optional: Verify that you prepared the upgrade template correctly by running a basic template verification.

   ```
   vcsa-deploy upgrade --verify-template-only path_to_the_json_file
   ```
3. Optional: Gather and validate the upgrade requirements by running a pre-upgrade check.

   ```
   vcsa-deploy upgrade --precheck-only path_to_the_json_file
   ```

   The pre-upgrade check installs the Upgrade Runner on the source appliance that you want to upgrade without upgrading the appliance.

   The Upgrade Runner validates the configurations such as ESX, network settings, and NTP servers. The Upgrade Runner also checks if you have selected a suitable deployment size and storage size for the new appliance against the compute resources required for the upgrade.
4. Perform the upgrade by running the following command.

   ```
   vcsa-deploy upgrade --accept-eula optional_arguments path_to_the_json_file
   ```

   Use *`optional_arguments`* to enter space-separated arguments to set additional execution parameters of the upgrade command.

For example, you can set the location of the log and other output files that the installer generates. This example also confirms participation in the VMware Customer Experience Improvement Program (CEIP). If the `ceip_enabled` parameter is set to true in the JSON deployment template, you must include the argument `--acknowledge-ceip`.

```
vcsa-deploy upgrade --accept-eula --acknowledge-ceip --log-dir=path_to_the_locationpath_to_the_json_file
```

Verify Your vCenter Upgrade Is Successful.

Syntax of the CLI Upgrade Command

You can use command arguments to set the execution parameters of the upgrade command.

You can add a space-separated list of arguments to the CLI upgrade command.

```
vcsa-deploy upgrade path_to_the_json_file list_of_arguments
```

Argument	Description
`--accept-eula`	Accepts the end-user license agreement. Required for executing the deployment command.
`--acknowledge-ceip`	Confirms your acknowledgment of your VMware Customer Experience Improvement Program (CEIP) participation. Required if the `ceip_enabled` parameter is set to `true` in the JSON deployment template.
`-v`, `--verbose`	Adds debug information to the console output.
`-t`, `--terse`	Hides the console output. Displays only warning and error messages.
`--log-dir` *LOG_DIR*	Specifies the location of the log and other output files that the installer generates.
`--skip-ovftool-verification`	Performs basic verification of the configuration parameters and deploys the vCenter appliance, but does not validate the OVF Tool parameters in the `ovftool_arguments` subsection of the JSON template. If you set arguments that the OVF Tool does not recognize, the deployment might fail.
`--no-ssl-certificate-verification`	Prohibits SSL verification of for all server connections. The CLI verifies that a server's security certificate is signed by a Certificate Authority (CA), and establishes a secure connection. If the certificate is self-signed, the CLI stops the upgrade unless you specify that the CLI ignore the self-signed certificate using the `--no-ssl-certificate-verification` command parameter. If you are connecting to a server with a self-signed certificate, and fail to specify that the CLI accept it, the CLI displays the server's self-signed certificate thumbprint, and prompts you to accept or reject it. You can also specify that the CLI ignore self-signed certificates using the `ssl_certificate_verification` configuration parameter in the JSON template. See Upgrade Configuration Parameters for CLI Upgrade of vCenter Appliance . **Important:** Avoid using this option as it may cause problems during or after upgrade due to an un-validated identity of the target host.
`--operation-id`	Lets you provide an identifier to track the concurrent installation, migration, or upgrade of multiple vCenter instances. If do not provide an operation ID, the CLI generates a universally unique identifier (UUID) which you can use to identify the different instances of vCenter and their installation or upgrade status.
`--pause-on-warnings`	Pauses and waits for acknowledgment of warnings.

Argument	Description
`--verify-template-only`	Performs basic template verification without installing Upgrade Runner, running prechecks, and upgrading or migrating the vCenter appliance.
`--precheck-only`	Installs Upgrade Runner on the source appliance and runs a complete set of prechecks without performing the upgrade.
`--upgrade-framework`	Lets you provide the framework for the type of upgrade you want to perform. Specify `legacy` to run the regular upgrade process or `reduced_downtime_upgrade`.
`-h, --help`	Displays the help message for the `vcsa-deploy upgrade` command.
`--template-help`	Displays the help message for the use of configuration parameters in the JSON upgrade file.

After the execution finishes, you can get the exit code of the command.

Exit Code	Description
0	Command ran successfully
1	Runtime error
2	Validation error
3	Template error

Reduced Downtime Upgrade

Reduced downtime upgrade is a migration-based approach to upgrade vCenter between major and minor versions that reduces downtime to less than 5 minutes under ideal network, CPU, memory, and storage conditions.

You can perform a reduced downtime upgrade for single self-managed vCenter instances, vCenter instances managed by another vCenter, vCenter instances enabled with vCenter HA, and vCenter instances connected in Enhanced Linked Mode configuration.

Supported Upgrade Paths

Source Version	Target Version	Upgrade Interface and Capabilities
vCenter 9.1.0	vCenter 9.1.1	Full reduced downtime upgrade support by using the vSphere Client wizard and the `vcsa-deploy` CLI. vCenter HA and Enhanced Linked Mode supported.
vCenter 9.0.x	vCenter 9.1 / vCenter 9.1.1	Full reduced downtime upgrade support by using the vSphere Client wizard and the `vcsa-deploy` CLI. vCenter HA and Enhanced Linked Mode supported.
vCenter 8.0 Update 3	vCenter 9.1 / vCenter 9.1.1	Full reduced downtime upgrade support by using the vSphere Client wizard and the `vcsa-deploy` CLI. vCenter HA and Enhanced Linked Mode supported.
vCenter 8.0 Update 2	vCenter 9.1 / vCenter 9.1.1	Full reduced downtime upgrade support by using the vSphere Client wizard and the `vcsa-deploy` CLI. First version to support reduced downtime upgrade for vCenter HA clusters.

Source Version	Target Version	Upgrade Interface and Capabilities
vCenter 8.0 P02	vCenter 9.1 / vCenter 9.1.1	CLI reduced downtime upgrade support by using the `vcsa-deploy` CLI only. Minimum source patch level for reduced downtime upgrade. The vSphere Client wizard and vCenter HA reduced downtime upgrade are not available on this version.
vCenter 8.0 Update 1 vCenter 8.0	vCenter 9.1 / vCenter 9.1.1	**Not supported.** Use the standard two-stage migration upgrade, or update the source to vCenter 8.0 P02 or later to use reduced downtime upgrade.

Note:

Reduced downtime upgrade is not available for vCenter HA clusters of versions earlier than vCenter 8.0 Update 2.

Note:

vCenter 8.0 P02 is the minimum source patch level containing reduced downtime upgrade engine binaries. Source vCenter instances on 8.0 P02 can perform reduced downtime upgrade to 9.1.1 by using the `vcsa-deploy` CLI.

To use the vSphere Client wizard for reduced downtime upgrade or to upgrade a vCenter HA cluster, update the source instance to vCenter 8.0 Update 2 or later.

About the Reduced Downtime Upgrade Process

The reduced downtime upgrade process uses a migration-based approach. In this approach, a new vCenter appliance is deployed and the current vCenter data and configuration is copied to it. The reduced downtime upgrade does not replace the current vCenter upgrade process.

During the reduced downtime upgrade process, the source vCenter appliance and all resources remain online. The downtime occurs when the source vCenter appliance is stopped, the configuration is switched over to the target vCenter, and the services are started. The downtime is expected to take less than 5 minutes under ideal network, CPU, memory, and storage provisioning.

You can use either the vSphere Client or the CLI method to perform the reduced downtime upgrade.

Reduced Downtime Upgrade in High Availability Environments

Reduced downtime upgrade is integrated with vCenter HA deployment.

The reduced downtime upgrade is integrated with the vCenter HA automatic and manual configuration deployment, including self-managed vCenter and non-self-managed vCenter.

You can use the vSphere Client and API-based approaches to perform a reduced downtime upgrade in a high availability (HA) environment.

For more information, see Reduced Downtime Upgrade for vCenter HA.

Reduced Downtime GUI Upgrade

You can use the vSphere Client to perform a reduced downtime upgrade of a vCenter appliance.

The high-level steps for the reduced downtime upgrade are:

1. Configure the repository URL.

Note:

Perform this step when you are upgrading from versions earlier than vSphere 8.0 Update 2 to vSphere 8.0 Update 2 or later versions.

Go to Step 2 if you are upgrading from vSphere 8.0 Update 2 to later versions.

2. Select the target upgrade version for your vCenter choosing from the available version in the Broadcom online software depot or from the downloaded and mounted ISO files.
3. Verify that you have a backup of the source vCenter appliance.
4. Upgrade the vCenter Lifecycle Manager service plug-in and run prechecks.
5. Configure the target vCenter appliance.
6. Prepare the upgrade and and switch over to the target vCenter appliance.

Validations are run at every stage of the process. If you face an issue, resolve the issue and retry the upgrade steps. If the upgrade is canceled or an error occurs at any stage, the configuration reverts to the source vCenter instance. The source vCenter instance does not shut down until the upgrade process is complete and the target vCenter is up and running.

Note:

In the event of a failure, the upgrade process is cancelled automatically and the configuration reverts to the source vCenter instance. The vCenter Lifecycle Manager service plug-in does not revert.

Configure a Custom Repository URL

You can configure the vCenter appliance to use the default or a custom repository URL as the target version. By default the current repository for URL-based patching is the legacy public VMware repository URL.

Log in to the vCenter Appliance Management Interface (VAMI) as root.

There are two ways for configuring the repository URL:

- If vCenter is not connected to the Internet or if your security policy does not allow you to connect to the Internet, you can build and configure a custom repository. The custom repository runs on a local web server within your data center and replicates the data from the default repository.

  Note:

  You must perform this procedure when you are upgrading from versions earlier than vSphere 8.0 Update 2.
- If your vCenter system is connected to the Internet, you must replace the default download URL with the Broadcom online repository URL that requires a customer-specific token. See Download Updates from the Broadcom Online Repository.

1. If you want to configure a custom repository URL, build the repository on your local web server.
2. Log in to the Broadcom Support Portal.
3. Download the vCenter appliance ISO image. See Broadcom knowledge base article 366685.
4. Confirm that the md5sum is correct by using an MD5 checksum tool.
5. On your web server, create a repository directory under the root.

   For example, create the `vc_update_repo` directory.
6. In the vCenter Appliance Management Interface, click **Update**.
7. Click **Settings**.
8. Select the Repository settings.

Option	Description
Default	Uses the legacy VMware repository URL that is preset for the build profile of the appliance. This download URL is no longer active and must be replaced with the new Broadcom online repository. See Broadcom knowledge base article 390120.
Specified	Uses a custom repository download URL. You can enter the custom repository URL, for example, *`https://`*

Option	Description
	web_server_name.your_company.com/ vc_update_repo. The custom repository URL must use a secure protocol such as HTTPS or FTPS.

9. Optional: If the specified repository requires authentication, enter the user name and password.
10. If you do not want to perform a security certificate check, deselect the **Check Certificate** check box.
    If you trust the URL for the repository, you can choose to bypass the certificate check for the repository URL.
11. Click **SAVE**.

    In the **Current version details** pane, you can view the vCenter version and build number.

Download and Mount the ISO Image

VMware releases the vCenter appliance ISO image, which contains the installers for the vCenter appliance.

- Create an account at https://support.broadcom.com/.
- Verify that you have the following privileges:
  - **Virtual machine .Interaction.Configure CD media** on the virtual machine.
  - **Datastore.Browse datastore** on the datastore to which you upload the installation media ISO image.
  - **Datastore.Low level file operations** on the datastore to which you upload the installation media ISO image.
- Download the ISO image to the content library or datastore connected to the vCenter virtual machine or the Management vCenter.
- Mount the ISO image on the CD-ROM device of the vCenter virtual machine.

1. Log in to the Broadcom Support Portal.
2. Click the software divisions drop-down menu next to your user name, and select **VMware Cloud Foundation**.
3. On the left-hand side, click **My Downloads** and search for VMware vSphere Foundation (VVF) or VMware Cloud Foundation (VCF).

   After selecting the right version of one of the products, a list of its components is displayed.
4. Review and accept the Terms and Conditions.
5. Click the **View Group** button to view all vCenter download options.
6. Click the download button next to the vCenter appliance ISO image to download it.
7. In vSphere Client, right-click a virtual machine in the vCenter inventory and select **Edit Settings**.
8. Expand **CD/DVD drive**, and select **Datastore ISO File** from the drop-down menu.
   The **Select File** dialog box opens.
9. Browse to select the file that you downloaded and click **OK**.
10. Select **Connect At Power On** to connect the device when the virtual machine powers on.
11. Click **OK**.
12. Expand the **VM Hardware** panel and click the **Connected** icon next to the datastore ISO file to connect the device.

Download Updates from the Broadcom Online Repository

You can download the latest patches and updates directly from the Broadcom online software repository.

Log in to the vCenter Appliance Management Interface (VAMI) as root.

With vCenter 9.1, you can provision your custom URL to the Broadcom online repository and can download all latest updates and patches available. See Broadcom knowledge base article 390120.

In an air-gapped environment, you can build and configure a custom repository. See Configure a Custom Repository URL.

1. In the vCenter Appliance Management Interface, click **Update**.
2. Click **Settings**.
3. Select the Repository settings.

Option	Description
Default	Use the legacy VMware repository URL that is preset for the build profile of the appliance. These download URLs are no longer active and must be replaced with the new Broadcom online repository. See Broadcom knowledge base article 390120.
Specified	Use the Broadcom online repository URL. You can enter the Broadcom online repository URL, for example, `https://dl.broadcom.com/<download_token>/PROD/COMP/VCENTER/vmw/8d167796-34d5-4899-be0a-6daade4005a3/9.1/`. For more information about how to reconfigure the default online repository, see Broadcom knowledge base article 390120.

4. If you do not want to perform a security certificate check, deselect the **Check Certificate** check box.

   If you trust the URL for the repository, you can choose to bypass the certificate check for the repository URL.
5. Click **Save**.

   In the **Current version details** pane, you can view the vCenter version and build number.

Upgrade the vCenter Lifecycle Plug-in

After you download and mount the ISO image, upgrade the vCenter Lifecycle plug-in.

- Verify that you have downloaded and mounted the ISO image in an air-gapped environment. See Download and Mount the ISO Image.
- Verify that you have reconfigured the Broadcom online repository download URL. See Download Updates from the Broadcom Online Repository.
- Verify that you have a backup of the source vCenter appliance.
- Concurrent upgrades are not supported.
- Perform steps 3-5 if you are upgrading from a version earlier than vSphere 8.0 Update 2.
- If you are upgrading from version vSphere 8.0 Update 2 or later versions, you can mount the ISO file and can upgrade the plug-in.

With vCenter 9.1 and later, when the upgrade of the vCenter Lifecycle plug-in fails, your vCenter system is reverted to its original state. The automatic rollback is a configurable option which is enabled by default. See Configure the Automatic Rollback of the vCenter Lifecycle Plug-In.

1. In the vSphere Client, select the vCenter that you want to upgrade.
2. On the **Updates** tab, click **vCenter Server** > **Upgrade**.
3. Click **Target Version** and select one of the available options.

Upgrade Option	Description
Upgrade with online depot	If you reconfigured the download URL to use the Broadcom online repository, you can select from the latest available updates and patches for vCenter. See Download Updates from the Broadcom Online Repository.
Upgrade with ISO file	If you configured the vCenter appliance to use the custom repository URL, you can select from the downloaded and mounted ISO files. See Configure a Custom Repository URL.

4. From the **Target Version** field, click **Select version**.

   The **Select the available update** popup dialog opens.

5. Select the vCenter version and click **OK**.
6. Click **Next**.
7. In **Backup**, select the check box to indicate that you have backed up the vCenter.
   The backups are listed.
8. In **Upgrade Plug-in**, select **Upgrade plug-in** to update the vCenter Lifecycle service plug-in.
   After the plug-in upgrades, the UI reloads with the version from the ISO file.
9. Click **Next** to proceed with configuring the target vCenter appliance.

   Warning:
   Clicking **Next** before the upgrade completes might result in crash of the plug-in. Wait for the progress bar to reach 100% before you click **Next**.

10. Click **Run prechecks** to run source prechecks and click **Next**.
11. Optional: Click **Discard** to discard the upgrade workflow and return to the mount the ISO step.

    With vCenter 9.1 and later, the vCenter Lifecycle plug-in reverts to its previous state.

Configure the Automatic Rollback of the vCenter Lifecycle Plug-In

You can configure the upgrade behavior of the vCenter Lifecycle plug-in to automatically roll back to its previous state in case the upgrade fails.

1. Log in to the vCenter appliance as the root user.
2. Set the value of the `async_patch` > `enabled` field to `false` to deactivate the automatic rollback of the vCenter Lifecycle plug-in.

   By default the automatic rollback option is activated.

```
root@<vcenter_PNID> [ /etc/applmgmt/appliance ]# cat patching_backup_config.json
{
   "backup" :
   {
     "cap_registry": "/usr/lib/vmware-capengine/scripts/user_registry.sh",
     "cap_status_url": "http://127.0.0.1:15051/capengine/api/v1/workflow/instance/{0}",
     "cap_url": "http://127.0.0.1:15051/capengine/api/v1/workflow/execute",
     "enable_auto_backup": true,
     "partitions_to_exclude": "log_vg,lifecycle_vg",
     "patching_user": "patchingOrchestrator",
     "pwd_len": 16,
     "retry_count": 4,
     "retry_interval": 1,
     "snapshot_size": "10%",
     "snapshot_profile": "vg_root_0:100%,db_vg:30%,dblog_vg:30%",
     "status_retry_count": 1800,
     "include_boot_backup_restore": "yes"
   },
   "async_patch" :
   {
     "allowed_base_version" : "9.1.0.0",
     "enabled" : true
   }
 }
```

Configure the Target vCenter appliance

When the vCenter Lifecycle service plug-in update completes, configure the target vCenter appliance.

After the upgrade, the target vCenter has the same IP address and identity as the source vCenter.

1. In **Upgrade**, go to the **Target Appliance** section.
2. Click **Configure target appliance**.
   The **Target VM deployment** wizard appears.
3. Read and accept the license agreement, and click **Next**.
4. Review the VMware Customer Experience Improvement Program (CEIP) page and choose if you want to join the program.

   For information about the CEIP, see the Configuring Customer Experience Improvement Program section in *vCenter and Host Management*.
5. Click **Next**.
6. Enter location details if the source vCenter is managed by another vCenter.
   Enter the container location, HTTPS port, user name,and password of the source vCenter.
7. View and accept the certificate of the managing vCenter which manages the source vCenter and click **Next**.
8. Optional: In **HA Containers Locations**, enter the details of the managing vCenter which manages the Passive and Witness nodes if the vCenter HA is configured with the manual configuration,

   You can enter the details of the managing vCenter which manages the Passive and Witness nodes to create them automatically after the upgrade completes. If you do not enter the details, vCenter HA is removed during upgrade and you must configure HA manually after the upgrade completes.

   Enter the container location, HTTPS port, user name, and password of the vCenter that manages the Passive and Witness nodes.
9. Select where you want to deploy the target vCenter appliance and click **Next**.

   You can deploy the target vCenter appliance on the same location as the source appliance or choose a different location. If you select a different location, the target location must be a different vCenter or host and you must enter the connection details such as, host name or IP address, HTTPS port, user name, and password of the vCenter.

   Note:

   When vCenter HA (automatic or manual) is configured, you cannot deploy the target vCenter appliance on a different location.

   The **Deployment Type** page is displayed if you choose to deploy the target on the same location as the source vCenter appliance.
10. If you select a different location for the target vCenter, view and accept the certificate of the target deployment and click **Next**.
11. Select the deployment type of the target vCenter appliance and click **Next**.
    Select **Same configuration** to deploy the target vCenter appliance with same configuration as the source.

    Select **Detailed configuration** to enter all the configuration parameters for the target appliance.

    When vCenter HA (automatic or manual) is configured, you cannot provide detailed configuration parameters.

    a) Select the data center or virtual machine folder where you want to deploy the target vCenter appliance.
    b) Select the compute resource required for the target deployment.
    c) Click **Next**.
12. Configure the target VM appliance details and click **Next**.

    Enter the VM name and set and confirm the temporary root password. By default, the VM name is same as the source after the upgrade. You can retain it or enter a different VM name.

13. Select a deployment size and storage size for the target vCenter and click **Next**.
14. Select a datastore for the deployment and click **Next**.

    Optionally, enable thin provisioning.
15. In the **Network Settings** page, enter a temporary IP address of the target vCenter for static deployments.

    This IP address is used during the deployment of the target vCenter appliance, during upgrade and for switchover.

    If the temporary IP address mode is DHCP, you do not need to enter the IP address.

    If you select **Automatic**, the temporary IP address is automatically discovered from the local link layer IP range and you are not required to provide the IP address.
16. In the **Review** page, review the configuration and click **Finish**.

    The **Target Appliance** section under the **Upgrade** window appears.
17. To change the settings, click **Edit configuration** and make the changes required.
18. Click **Next** to proceed with the upgrade and switchover.
19. Click **Discard** to discard the upgrade workflow and return to the mount the ISO step. The vCenter Lifecycle plug-in does not revert.

    You cannot discard the configuration when the upgrade is progress.

Prepare Upgrade and Switch Over to the Target vCenter appliance

Once the target vCenter appliance is configured, you can upgrade and switch over the services to it.

The upgrade and switchover happen in two stages.

- **Preparation** - The first stage is the preparation stage where the upgrade is initialized and the target vCenter appliance is created with the configuration that you entered. During this stage, data from the source machine is replicated on the target machine. The duration of this process depends on your environment and the vCenter usage patterns.
- **Switchover** - The second stage is the switchover stage where the target vCenter appliance assumes the identity of the source appliance. During the switchover, there is a short downtime. You can choose a manual, automatic, or scheduled switchover.

The switchover process retains the source vCenter appliance. After the switchover completes, the source appliance remains powered off in the inventory, and the switchover process does not delete it. You must delete the source vCenter virtual machine manually after the switchover completes.

The switchover process shuts down the guest operating system of the source appliance. The timing of the shutdown depends on the source shutdown option that you select before starting the upgrade: during the upgrade or after the upgrade succeeds.

After a successful upgrade, the upgrade process appends an `-old` suffix to the source virtual machine name, and the target vCenter appliance takes the original name of the source virtual machine.

> **Important:**
>
> If the automated shutdown of the source vCenter appliance does not succeed, a warning message appears. Shut down the source appliance manually.

1. In **Update Planner**, go to the **Upgrade** section.
2. Click **Start upgrade**.
3. Select the type of switchover that you want to perform.
   - **Manual Switchover** - Select this option if want to manually switch over to the target vCenter appliance. You must click **Switchover** to trigger the switchover after the target appliance is created with the selected configuration.
   - **Automated Switchover** - Select this option to continue with an automatic switchover after the target appliance is created with the selected configuration.
   - **Scheduled Switchover** - Use this option to schedule the switchover for a time that is a minimum of 4 hours later than the current time.

4. If you select manual switchover, enter the switchover information.

   When the preparation stage completes and the switchover starts, you can see the status of the switchover stage.

   After the switchover completes, you can log in to the target vCenter appliance.

5. Click **Open vSphere Client** to log in.

   Note:

   If the upgrade fails, the configuration reverts to the source vCenter appliance.

Reduced Downtime CLI Upgrade

You can use the CLI installer to perform the reduced downtime upgrade of a vCenter appliance.

The CLI upgrade process includes downloading the vCenter appliance installer on a network virtual machine or physical server from which you want to perform the upgrade, preparing a JSON configuration file with the upgrade information, and running the upgrade command.

The vCenter appliance ISO file contains templates of JSON files that contain the minimum configuration parameters that are required for upgrading a vCenter appliance.

When you run the command to perform the reduced downtime upgrade, the installer patches the vSphere Lifecycle Manager, runs the CLI prechecks and the reduced downtime upgrade prechecks, and calls the Reduced Downtime Upgrade APIs.

CAUTION:

If NSX is not upgraded to a compatible version before the vCenter upgrade, the reduced downtime upgrade state will show as `Blocked`. The reduced downtime upgrade may remain in a blocked state even if the CLI session times out. Upgrade NSX to a compatible version to proceed the reduced downtime upgrade.

Prepare Your JSON Configuration File for the Reduced Downtime CLI Upgrade

Before you run the CLI command to perform the reduced downtime upgrade, you must prepare a JSON file with configuration parameters and their values for your upgrade specification.

- You must be familiar with the JSON syntax.
- Download and Mount the vCenter installer.

The vCenter installer contains JSON templates for all upgrade types. For information about the templates, see JSON Templates for CLI Upgrade of the Appliance.

For a complete list of the configuration parameters and their descriptions, navigate to the installer subdirectory for your operating system and run the `vcsa-deploy upgrade --template-help` command or see Upgrade Configuration Parameters for CLI Upgrade of Appliance.

1. In the the vCenter installer, navigate to the `vcsa-cli-installer` directory, and open the `templates` subfolder.
2. Copy the `upgrade` templates from the `upgrade` subfolder to your workspace.
3. Open the template file for your use case in a text editor.

   To ensure the correct syntax of your JSON configuration file, use a JSON editor.
4. Fill in the values for the required configuration parameters and, optionally, enter additional parameters and their values.
5. Optional: Use a JSON editor of your choice to validate the JSON file.
6. Save in UTF-8 format and close the file.

JSON Templates for the Reduced Downtime CLI Upgrade

The installer contains JSON templates that are located in the vcsa-cli-installer/templates directory. In the upgrade subfolder, you can find the JSON templates with the minimum configuration parameters for all upgrade types.

For each upgrade type, there is one template for deploying the new appliance on an ESX host and another template for deploying the new appliance on a vCenter instance.

For information about the templates, see JSON Templates for CLI Upgrade of the Appliance.For a complete set of parameters required for upgrade, see Upgrade Configuration Parameters for CLI Upgrade of Appliance.

Perform a Reduced Downtime Upgrade by Using the CLI

You can use the CLI installer to perform an reduced downtime upgrade of a vCenter appliance. You must run the upgrade from a Windows, Linux, or Mac machine that is in the same network as the appliance that you want to upgrade.

- Prepare Your JSON Configuration File for the Reduced Downtime CLI Upgrade.
- Review the arguments for running the CLI upgrade. See Syntax of the CLI Upgrade Command.
- Verify that the user name with which you are logged in to your machine, the path to the vCenter appliance installer, the path to your JSON configuration file, and the string values in your JSON configuration file contain only ASCII characters. Extended ASCII and non-ASCII characters are not supported.

1. Navigate to the `vcsa-cli-installer` subdirectory for your operating system.
   - If you are running the upgrade on Windows, navigate to the `vcsa-cli-installer\win32` directory.
   - If you are running the upgrade on Linux, navigate to the `vcsa-cli-installer/lin64` directory.
   - If you are running the upgrade on Mac, navigate to the `vcsa-cli-installer/mac` directory.
2. Optional: Verify that you prepared the upgrade template correctly by running a basic template verification.

   ```
   vcsa-deploy upgrade --verify-template-only path_to_the_json_file
   ```
3. Perform the reduced downtime upgrade by running the following command.

   ```
   vcsa-deploy upgrade --upgrade-framework reduced_downtime_upgrade path_to_the_json_file
   ```

   Or

   ```
   vcsa-deploy upgrade path_to_the_json_file
   ```

   To run the existing upgrade runner, run the following command

   ```
   vcsa-deploy upgrade --upgrade-framework legacy path_to_the_json_file
   ```

   The installer patches the vSphere Lifecycle Manager, runs the CLI prechecks and the reduced downtime upgrade prechecks, and calls the Reduced Downtime Upgrade APIs.

After Upgrading vCenter

After you upgrade vCenter 9.1, consider the post-upgrade options and requirements.

- Go to VMware Cloud Foundation Operations and assign your vCenter instance a license.
- Activate your vCenter instance for management by the VCF Operations cluster. See Broadcom knowledge base article 424630.
- Complete any component reconfigurations that might be required for changes during the upgrade or Reduced Downtime Upgrade cutover.
- Verify that you understand the authentication process and identify your identity sources. For detailed steps on verifying and reconfiguring Active Directory (LDAPS / IWA) or OIDC identity provider federation post-upgrade, see Identity Sources for vCenter with vCenter Single Sign-On.
- Upgrade any additional extension modules or third-party solution plugins that are linked to this instance of vCenter, such as VMware NSX, VMware Live Site Recovery, VMware Cloud Foundation Operations® (formerly VMware Aria Operations), and backup and monitoring applications.
- Optionally, upgrade the ESX hosts in the vCenter inventory to the same version as the vCenter instance using vSphere Lifecycle Manager cluster image management.
- If you are using smart card authentication, ensure to keep the smart card port open in the client environment. By default, the smart card port is open in vCenter. For details about the smart card port, see the VMware Ports and Protocols Tool™ at https://ports.broadcom.com

- If you plan to install Windows 11 as a guest operating system on a virtual machine, you must configure a key provider. Installing Windows 11 requires a Trusted Platform Module (TPM) 2.0. When installing Windows 11 as a guest operating system on a virtual machine, instead of using a physical TPM, you can use a virtual Trusted Platform Module (vTPM). A vTPM is a software-based representation of a physical TPM 2.0 chip. A vTPM depends on virtual machine encryption to secure vital TPM data, and so requires that you configure a key provider. For information about the key providers supported by vSphere, see the *Virtual Machine Encryption* chapter in the *vSphere Security* documentation. The easiest way is to configure a VMware vSphere®Native Key Provider™. vSphere Native Key Provider is included in all vSphere editions and does not require an external key server. For information about configuring a vSphere Native Key Provider, see *Configuring and Managing vSphere Native Key Provider* chapter in the *vSphere Security* documentation. As with all security solutions, consider the system design, implementation considerations, and tradeoffs of using vSphere Native Key Provider.
- If you had modified the DRS cluster automation level before upgrade, you can either continue to use the modified settings or revert the automation level to fully automated.
- Perform a baseline VAMI File-Based Backup (port `5480`) immediately following upgrade completion to establish an initial post-upgrade restore point.
- Retain the powered-off source vCenter appliance VM in the inventory for a 3 to 7 days observation period to verify stability, then permanently delete it from disk to reclaim datastore capacity. Do not power on the source VM on the production network post-upgrade.

Verify Your vCenter Upgrade Is Successful

You can verify the success of your vCenter upgrade.

You must be logged into the upgraded vCenter instance. If you created a reference of required information based or a CLI template, you can use it to validate the upgrade or migration success.

1. Verify that the IP address is correct.
2. Verify that the Active Directory registration has not changed.
3. Verify the Network registration is correct.
4. Verify the Domain is correct.
5. Verify the certificates are valid.
6. Verify the inventory data is correctly migrated.
   a) Review the events history.
   b) Review the performance charts.
   c) Review the users, permissions, and roles.

If the postupgrade configuration conforms to your required information or CLI template reference and expectations, the vCenter upgrade or migration is complete.

Use the vSphere Client to log in to the vCenter instance. See Log in to Your vCenter by Using the vSphere Client.

Reregister Plug-In Solution in vCenter After Upgrade or Migration

You reregister a previously registered plug-in solution and any third-party client plug-in packages with vCenter after the SSL certificate has been refreshed following an upgrade or migration.

Consult the vendor documentation for any solution-based vCenter extensions and client plug-ins for instructions to re-register after a vCenter upgrade or migration.

If the procedure provided by your plug-in solution vendor fails to reregister the plug-in, you can use the following procedure to remove the plug-in registration, and then register it again with vCenter. For information on registering plug-ins, see the *vCenter and Host Management* documentation. For information on removing or disabling unwanted plug-ins from vCenter, see Broadcom knowledge base article 344648.

1. In a web browser, navigate to the Managed Object Browser of your vCenter.
   `https://vcenter_server_ip_address_or_fqdn/mob/?moid=ExtensionManager`

2. Log in with your vCenter credentials.
3. On the `ManagedObjectReference:ExtensionManager` page, under Methods, click **UnregisterExtension**.
4. On the `void UnregisterExtension` page, in the text box inside the Value column, enter the value for the `key` property of the `Extension` data object of your vSphere Client extension.
5. To unregister the extension click **Invoke Method**.

Go to the solution registration page and register the plug-in.

Verify that your extension is registered successfully with vCenter by using one of the following approaches.

- In the vSphere Client, go to Administration and under Solutions, select **Client Plug-Ins** and click **Check for New Plug-Ins**.
- Log out and log in again to the vSphere Client. The vSphere Client checks for new plug-ins for each new user session.

Monitor and Manage Historical Data Migration

You can monitor and manage the background migration of historical data using the vCenter Management Interface.

- Verify that vCenter is successfully deployed and running.
- You must have selected to import historical data from the database in use by the previous version vCenter, to the embedded PostgreSQL database in vCenter 9.1. See Transferring Data from an Existing vCenter Appliance.

Using the vCenter Management Interface, you can perform the following data management tasks:

- Monitor the progress of the data migration.
- Pause the data migration.
- Cancel the data migration.

1. In a web browser, go to the vCenter Management Interface, https://*`appliance-IP-address-or-FQDN`*:5480.
2. Log in as root.

   The default root password is the password you set when deploying vCenter.
3. A status bar at the top of the vCenter Management Interface displays the percentage of data that has been copied from the source vCenter to the PostgreSQL database embedded in the target vCenter appliance.
4. To pause or cancel the data migration, click **Manage**.

Option	Description
Pause	During the data migration, vCenter performance might not be optimal. Pausing the migration lets vCenter run with better performance until such time that you can resume the process when it does not interfere with the needs of your business.
Resume	You can resume the data migration at a time that does not interfere with the business needs of your vCenter deployment.
Cancel	If you cancel the data import, the historical data will fail to import to the embedded PostgreSQL database. You cannot recover the data once you cancel the operation. If you cancel the import process, and want to import the historical data later, you must restart the upgrade or migration process from Stage 1 of the GUI installer.

When the data has been migrated, a success message displays in the vCenter Management Interface status bar.

Managing Software Updates, Upgrades, and Product Compatibility

You can view available vCenter updates and upgrades and produce interoperability reports about VMware products associated with vCenter. The reports help you plan vCenter updates and upgrades in your environment.

You can perform an interoperability check of VMware products within your environment against both source and target vCenter versions. You can also generate a pre-update report to ensure your environment meets the minimum software

and hardware requirements for a successful upgrade of vCenter. You can plan vCenter updates and upgrades based on the information in the reports you generate.

Note:

With vCenter 9.1 and later, you can perform interoperability check without joining the VMware Customer Experience Improvement Program (CEIP).

Note:

With vCenter 9.1 and later, you can perform interoperability checks in an air-gapped environment. First, download the compatibility data bundle and upload the file on your vCenter system. The compatibility data bundle holds all data from the Broadcom Compatibility Guide (BCG) combined with the Broadcom Product Interoperability Matrix.

For more information about how to download and use the compatibility data bundle in an air-gapped environment, see Broadcom knowledge base article 423296.

Interoperability report for the current vCenter	Lists VMware products in your environment and their compatibility against the current, or source, version of vCenter.
Interoperability reports for target versions of vCenter	Lists the VMware products in your environment and their compatibility against the target version of vCenter to which you want to upgrade.
Pre-update reports	With the pre-update report, you can ensure that your system meets the minimum software and hardware requirements for a successful upgrade of vCenter. The report provides information about problems that might prevent the completion of a software upgrade, and actions you can take to remedy those problems.

Monitor Interoperability for the Current vCenter Version

You can view an interoperability report that lists products in your environment associated with the current vCenter version and their compatibility.

Staring with vSphere 9.1, you can use Update Planner without joining the VMware Customer Experience Improvement Program (CEIP). For information about the CEIP, see the *Configuring Customer Experience Improvement Program* section in *vCenter and Host Management*.

The product interoperability report lists available products in your environment and their compatibility with the selected vCenter version.

Note:

In vSphere 9.1, you can perform interoperability checks in an air-gapped environment. First, download the compatibility data bundle and upload the file on your vCenter system. The compatibility data bundle holds all data from the Broadcom Compatibility Guide (BCG) combined with the Broadcom Product Interoperability Matrix.

For more information about how to download and use the compatibility data bundle in an air-gapped environment, see Broadcom knowledge base article 423296.

1. In the vSphere Client navigate to a vCenter for which you want to view an interoperability report.
2. On the **Monitor** tab, click **Interoperability**.

   The Product Interoperability report lists all available products in your environment associated with the selected vCenter.
3. (Optional) If there are VMware products in your environment that go undetected, you can manually add them to the list of products to check and regenerate the interoperability report.
   a) Click **Add Product** in the Product Interoperability pane.
   b) Select the VMware product and version you want to include in the interoperability report.

      Repeat this step for each VMware product you want to add to the report.

c) To add the selected products to the product inventory click **Done**.
d) Regenerate the report and verify that the products you added are included in the report.

4. (Optional) Click **Export** in the Product Interoperability pane to export and save a copy of the report as a comma-separated values (CSV) file, which allows data to be saved in a tabular format.

- Using the information in the report, you can apply patches and updates to your vCenter environment. See Patching and Updating vCenter 9.1 Deployments.
- You can generate a pre-upgrade report that lists actions that you must address to ensure a successful upgrade of vCenter in your environment. See Generate an Interoperability Report for Target vCenter Versions.

Generate an Interoperability Report for Target vCenter Versions

You can perform pre-checks and generate reports that provide product interoperability information for recommended update and upgrade versions of vCenter.

Staring with vSphere 9.1, you can use Update Planner without joining the VMware Customer Experience Improvement Program (CEIP). For information about the CEIP, see the *Configuring Customer Experience Improvement Program* section in *vCenter and Host Management*.

You can create a vCenter pre-update interoperability report to check the compatibility of VMware products in your environment against a pending version of vCenter. You can view the list of products in your environment that are associated with the current vCenter version, and whether those products are compatible with a suggested update version.

Note:

In vSphere 9.1, you can perform interoperability checks in an air-gapped environment. First, download the compatibility data bundle and upload the file on your vCenter system. The compatibility data bundle holds all data from the Broadcom Compatibility Guide (BCG) combined with the Broadcom Product Interoperability Matrix.

For more information about how to download and use the compatibility data bundle in an air-gapped environment, see Broadcom knowledge base article 423296.

1. In the vSphere Client, select a vCenter for which you want to view an interoperability report.
2. On the **Updates** tab, click **vCenter Server** > **Prechecks**.
3. Click **Select Version**.
4. Select the target version from the list of available updates and click **OK**.

   The list contains minor updates and major upgrade versions of vCenter.
5. Click **Product Interoperability** to view the report.
6. (Optional) If there are VMware products in your environment that go undetected, you can manually add them to the list of products to check and regenerate the interoperability report.
   a) Click **Modify Product List**.
   b) Select the VMware product and version that you want to include in the interoperability report.

      Repeat this step for each VMware product you want to add to the report.
   c) To add the selected products to the Update product inventory, click **Done**.
   d) Regenerate the report and verify that the products you added are included in the report.
7. (Optional) Click **Export** to save the report as a comma-separated values (CSV) file, which allows data to be saved in a tabular format.

- Using the information in the pre-upgrade report, you can apply patches and updates to your vCenter environment. See Patching and Updating vCenter 9.1 Deployments.
- You can generate a pre-upgrade report that lists actions that you must address to ensure a successful upgrade of vCenter in your environment. See Generate Pre-Update Reports.

Generate Pre-Update Reports

You can run pre-checks and generate reports that provide pre-update information. You use this information to make sure that your system meets the minimum software and hardware requirements to ensure a successful upgrade of vCenter.

When you generate a pre-update report, the report lists the actions you must address to ensure a successful upgrade of vCenter in your environment. The report also provides information about problems that might prevent the completion of a software upgrade or update.

1. In the vSphere Client, select a vCenter for which you want to view a pre-update report.
2. On the **Updates** tab, click **vCenter Server** > **Prechecks**.
3. Click **Select Version**.
4. Select the target version from the list of available updates and click **OK**.

   The list contains minor updates and major upgrade versions of vCenter.
5. Select **Source Prechecks** to view pre-update report.
6. (Optional) Click **Export** to save the report as a comma-separated values (CSV) file, which allows data to be saved in a tabular format.

- Using the information in the pre-upgrade report, you can apply patches and updates to your vCenter environment. See Patching and Updating vCenter 9.1 Deployments.
- You can generate an interoperability report that lists available VMware products in your environment, and the versions compatible with the vCenter version for which you are generating the report. See Generate an Interoperability Report for Target vCenter Versions.

Use the Latest Interoperability Data in an Air-Gapped Environment

You can generate update interoperability reports and perform system pre-checks for vCenter instances without Internet connectivity.

- Verify that you have a download token. See Broadcom knowledge base article 390098.

Starting with vCenter 9.1, you can use the VCF Download Tool to download binaries, metadata, and the compatibility data bundle from the Broadcom Support Portal. The compatibility data bundle combines the Broadcom Compatibility Guide (BCG) with the Broadcom Product Interoperability Matrix.

1. Download the VCF Download Tool from the Broadcom Support Portal.
   a) Log in to the Broadcom Support Portal and navigate to the **My Downloads** section.
   b) On the **Drivers & Tools** tab, search for the VCF Download Tool.
   c) Read and accept the *Terms and Conditions* and *Compliance Reporting Terms and Conditions*.
   d) Click the **HTTPS Download** icon next to the VCF Download Tool to initiate the download.
2. Navigate to the directory where you downloaded the VCF Download Tool and extract it.

   ```
   tar -xvzf vcf-download-tool-<vcf_product_version>.<build_number>.tar.gz
   ```
3. Run the VCF Download Tool on an Internet-connected system to download the latest compatibility metadata bundle.

   ```
   ./vcf-download-tool metadata download -d=<download_directory> --depot-download-token-
   file=<path_to_downloadtoken>.txt
   ```
4. Navigate to `<download_directory>/PROD/metadata/Compatibility`.

   The `/v1` and `/v2` directories contain the `VmwareCompatibilityData.json` files that provide the latest compatibility data.
5. Upload the downloaded compatibility data bundle to an offline vCenter system.
   a) Locate the compatibility data JSON files and compress them using the following command.

   ```
   cd <download_directory>/PROD/metadata/Compatibility
      gzip v1/VmwareCompatibilityData.json
   ```

b) Use Base64 encoding to convert the compressed binary data into a string format.

```
base64 v1/VmwareCompatibilityData.json.gz > compatibility_bundle_b64.txt
```

c) Log in to your vCenter system and copy the returned session ID.

```
curl -k -X POST -u 'username:password' https://<vcenter_ip_address_or_fqdn>/rest/com/vmware/cis/session
```

d) Send the compatibility data to your vCenter instance.

```
ENCODED_DATA=$(cat <encoded_compatibility_bundle_file_name>.txt)
curl --request PUT \
  --url 'https://<vcenter_ip_address_or_fqdn>/lcm/rest/vcenter/lcm/interop/bundle?vmw-task=true' \
  --header "vmware-api-session-id: <returned_session_ID>" \
  --header 'Content-Type: application/json' \
  --data "{\"data\": \"${ENCODED_DATA}\"}"
```

The API call returns the `task-id`, for example, `ea0a3939-2b97-4e8f-afee-cab46919a9da:com.vmware.vcenter.lcm.interop.interop_bundle`.

e) Use the `task-id` to view the result of the compatibility bundle upload task.

```
curl --request GET \
  --url https://<vcenter_ip_address_or_fqdn>/lcm/rest/cis/tasks/<returned_task_id> \
  --header "vmware-api-session-id: <returned_session_ID>"
```

The latest compatibility data bundle is uploaded to your vCenter instance in an air-gapped environment.

- You can generate an interoperability report that lists available VMware products in your environment, and the versions compatible with the vCenter version for which you are generating the report. See Generate an Interoperability Report for Target vCenter Versions.
- You can generate a pre-upgrade report that lists actions that you must address to ensure a successful upgrade of vCenter in your environment. See Generate Pre-Update Reports.

Patching and Updating vCenter 9.1 Deployments

VMware regularly releases patches for the vCenter. You can use the vCenter Appliance Management Interface (VAMI) or the appliance shell to apply patches to a vCenter.

VMware makes patches available on a monthly basis. These patches can only be applied in between major releases of vCenter. For example, patches released for the initial release of vCenter9.0, are not applicable to vCenter8.0 Update 1, as any patches previously made available will be included with the Update 1 release.

These patches can be for core product functionality, other packages in the vCenter such as Photon, or both.

Note:
You must use only the patches provided by VMware to update the packages in your vCenter. Updating these packages through any other means may impact the product functionality.

VMware distributes the available patches in two forms, one for ISO-based and one for URL-based models of patching.

- You can download the patch ISO images from the Broadcom Support Portal.
  VMware publishes a single type of ISO image that contains patches.

Download Filename	Description
`VMware-vCenter-Server-Appliance-`*`product_version-build_number`*`-patch-FP.iso`	Full product patch for the appliance, which contains the VMware software patches and the fixes related to security and third-party products (e.g. JRE and Photon OS components).

- You can configure the vCenter appliance to use a repository URL as a source of available patches.

Note:

The default online depot URLs are now unique for each customer. To update the default URLs of the online depot, see Broadcom knowledge base articles 390098 and 390120.

vCenter Quick Patches

You can apply express patches that carry security or critical bug fixes with minimal disruption to your workload management operations.

In vCenter 9.1, a mechanism is provided to apply a patch to your vCenter systems without disruption to your workload management operations. Such patches are called quick patches, and are delivered whenever there are some security or other critical bug fixes. Quick patches are not used to deliver major upgrades and updates.

Based on the services included in the patch payload, three groups of services are determined:

- Services with zero downtime such as `vlcm`, `vsphere-ui`, and `eam`. Upgrading services from this group does not impact the workload management operations.
- Services with near to zero downtime, up to 180 seconds such as `vmware-envoy` and `vmware-cis-license`. This group contains services that are critical for the workload management operations and must be restarted after an update.
- Services with downtime equivalent to the reduced downtime upgrade times, from 3 through 5 minutes. For example, `vmware-vpxd`, `vmca`, `lookupsvc`, and `vmware-vmon` have significant dependencies on other services and restarting them leads to cascading downtime for all dependant services. The downtime, that is required for a full recovery after a service from this group is restarted, is usually more than 3 minutes.

You can apply a quick patch to a vCenter system using the vCenter Management Interface and VCF API.

Patching vCenter Using the vCenter Management Interface

You can use the vCenter Management Interface to view the installed patches, check for new patches and install them, and configure automatic checks for available patches.

To perform ISO-based patching, you download an ISO image, attach the ISO image to the virtual CD/DVD drive of the appliance, check for available patches in the ISO image, and install the patches.

To perform URL-based patching, you check for available patches in a repository URL and install the patches. The vCenter is preset with a legacy VMware repository URL for the build profile of the appliance. You must reconfigure the appliance to use the Broadcom online repository repository URL or a custom repository URL, for example, a repository URL that you previously built on a local Web server running within your data center. See Download Updates from the Broadcom Online Repository and Configure a Custom Repository URL.

See Log In to the vCenter Appliance Management Interface.

Automatic Creation of LVM Snapshot

The vCenter patching orchestrator automatically creates a Logical Volume Manager (LVM) snapshot of the vCenter before performing a patch installation. If the patching fails, the orchestrator provides options to either continue patching after fixing the issue or roll back to the automatically created LVM snapshot, before starting the patching operation.

The rollback option is only available when you are patching vCenter 8.0 Update 2 and higher versions.

When you initiate the installation of a patch, prechecks are performed to verify that a snapshot can be taken and there is sufficient disk space for the LVM snapshot. If the precheck returns an error, the patching workflow exits.

After prechecks run successfully, the VMware Directory Services (`vmdird`) is stopped and the orchestrator takes an image-based backup (LVM snapshot). The snapshot is saved as snapshot disk on the vCenter appliance. If there is a failure while taking the snapshot, the `vmdird` is started in normal replication mode, an error is thrown and the patching workflow exits and the snapshot is cleaned up.

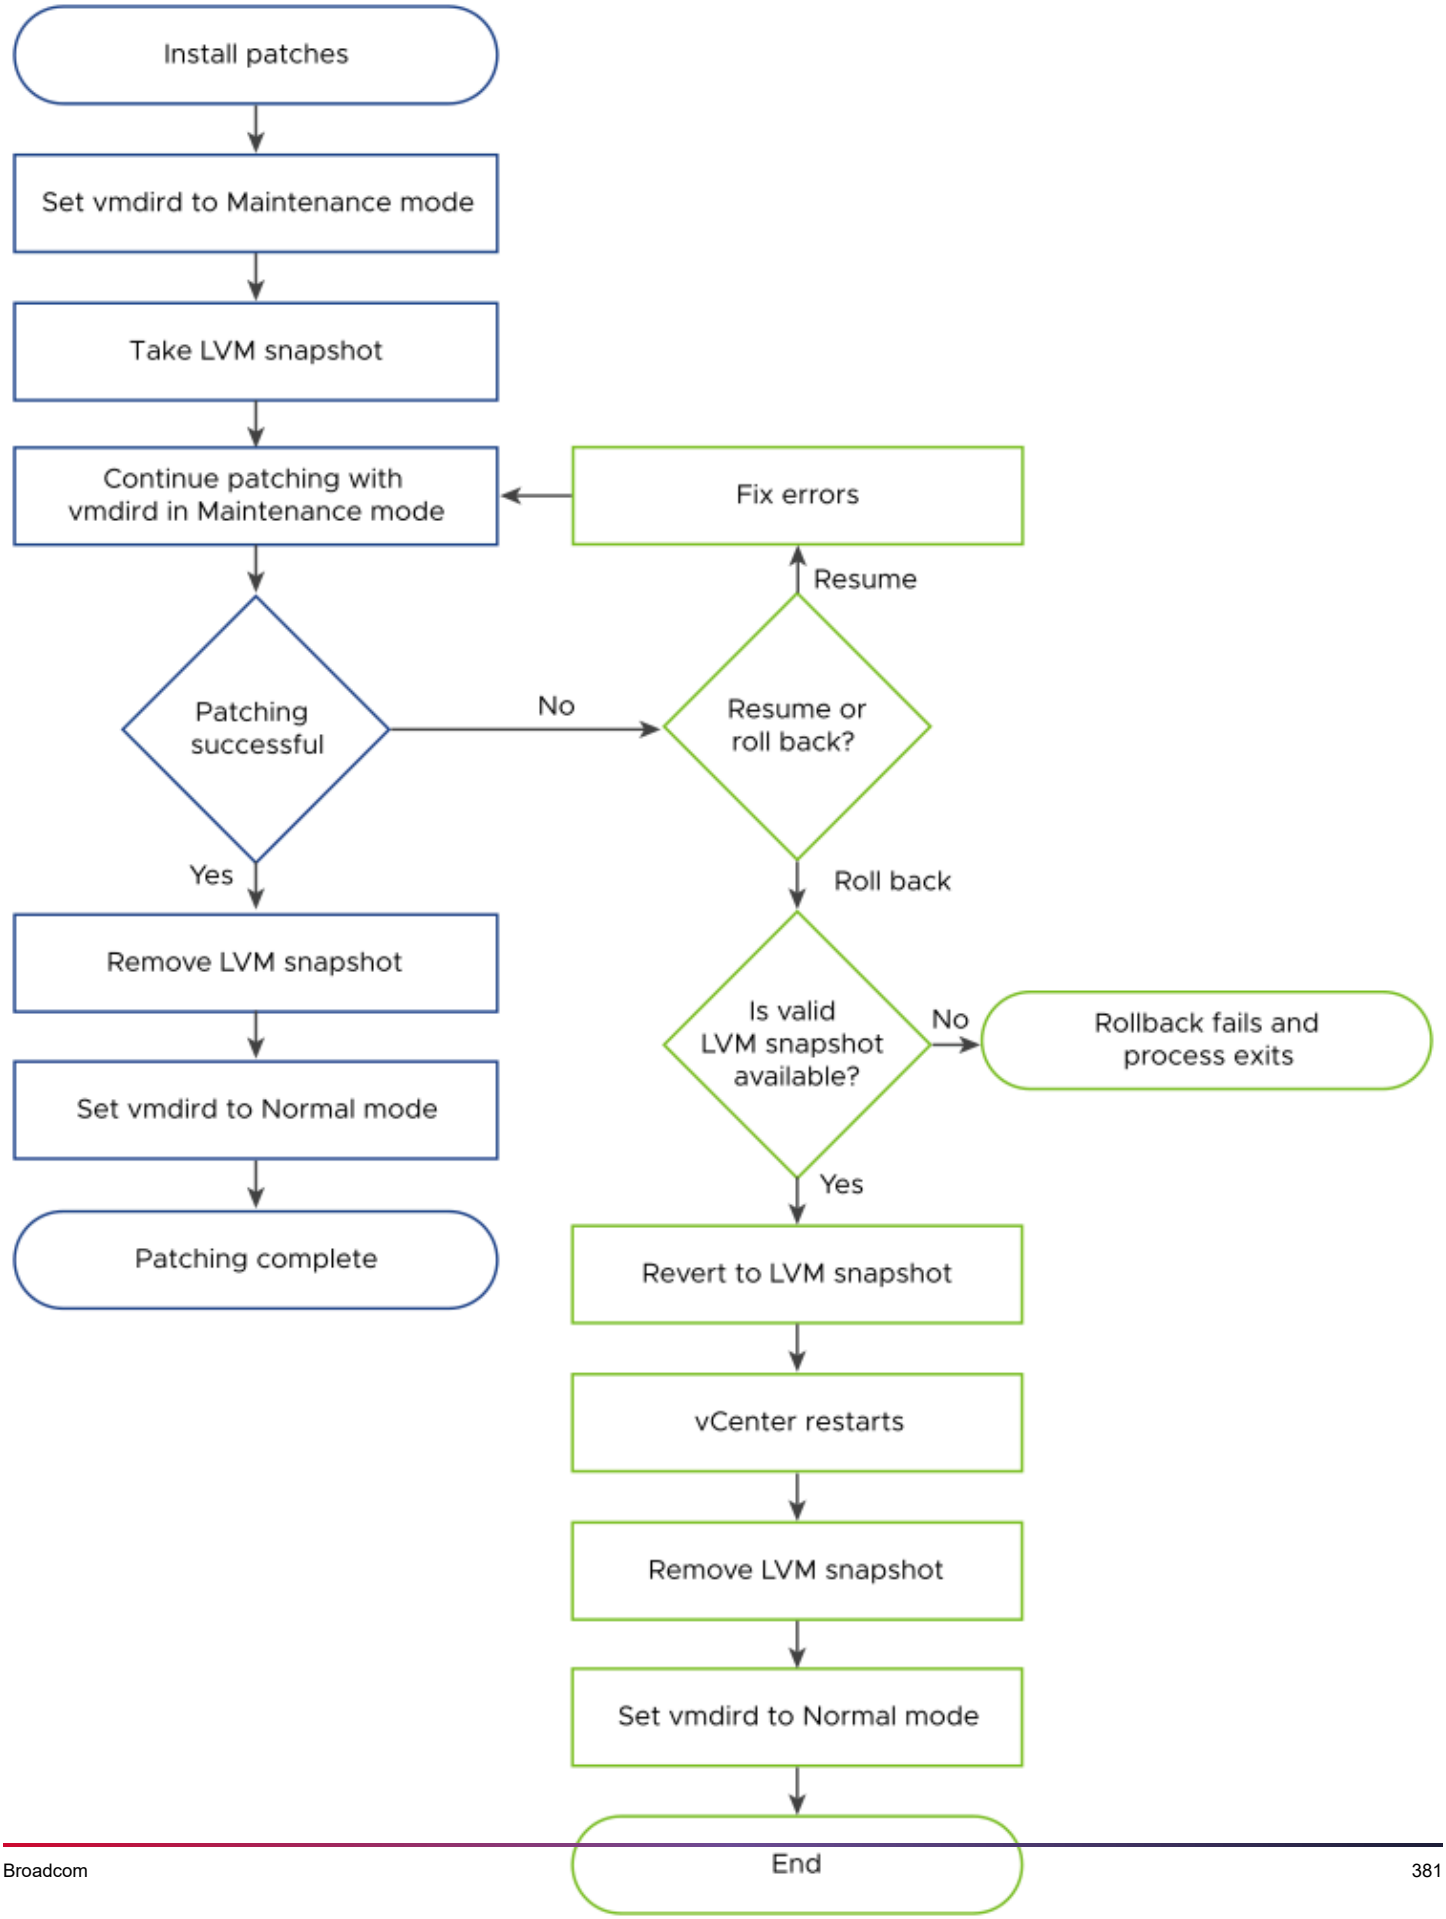
If the snapshot is taken successfully, the patching resumes with `vmdird` in standalone mode.

If an error occurs during patching, the vCenter Management Interface displays options to resume or roll back the process. You can select **Resume the vCenter installation** and correct the problem preventing the patching to finish staging the patches or select **Revert to the last vCenter backup version** to roll back.

If you choose to revert, a patching rollback API is called. The API checks if an LVM snapshot is available and reverts to the snapshot. After reverting, the snapshot is removed to reclaim the disk space and `vmdird` is set to normal replication

mode. The API also performs a cleanup of any changes made by the patching install workflow before creating the backup. If a valid snapshot is not available, the installation exits with an error.

Figure 26: Workflow for automatic creation of LVM snapshot and rollback



Check for and Stage Patches to the vCenter Appliance

Before you install available patches, you can stage the patches to the appliance. You can use the vCenter Management Interface to stage patches either from a local repository by attaching an ISO image to the appliance, or from a remote repository directly by using a repository URL.

- If you are staging patches from an ISO image that you previously downloaded from the Broadcom Support Portal, you must attach the ISO image to the CD/DVD drive of the vCenter. You can configure the ISO image as a datastore ISO file for the CD/DVD drive of the appliance using the vSphere Client. See *vSphere Virtual Machine Administration*.
- If you are staging patches from a remote repository or directly from the Broadcom online repository, verify that you have configured the repository settings and that the current repository URL is accessible. See Configure URL-Based Patching.

During the process of staging, the vCenter Management Interface validates that a patch is a VMware patch, that the staging area has enough free space, and that the patches are not altered. Only new patches or patches for existing packages that can be upgraded are staged.

If you are patching vCenter 8.0 Update 2 and higher versions, the patching orchestrator automatically creates a backup of the vCenter before performing a patch installation. For more information, see Automatic Creation of LVM Snapshot.

If a problem that prevents the successful staging of the patches occurs, vCenter suspends the staging process. Review the error messages, correct the problem, and, in many cases, you can resume staging the patches from the point at which vCenter encountered the problem.

1. Log in to the vCenter Management Interface as root.

   The default root password is the password you set when deploying vCenter.

2. Click **Update**.

3. Click **Check Updates** and select a source.

Option	Description
Check CD ROM + URL	Scans the attached ISO image as well as the configured repository URL for available patches.
Check CD ROM	Scans the ISO image that you attached to the CD/DVD drive of the appliance for available patches.

   In the Available Updates pane, you can view the details about the available patches in the source that you selected.

   Important:
   Some updates might require a reboot of the system. You can see information about these updates in the Available Updates pane.

   Note:

   Quick patches are marked with the **Quick patch** label. In the details view for an incoming quick patch, you can view the estimated downtime, the estimated patch install time, and the affected services.

4. You can run a pre-check of an update to verify that it is compatible with your current deployment.

5. Click the staging option that you would like to use.

Option	Description
Stage only	Stages the selected patches to the vCenter appliance for installation at a later time.
Stage and Install	Stages and installs the selected patches to the vCenter appliance. For more information on installing patches, see Install vCenter Patches.
Unstage	Unstages the selected patches.
Resume the vCenter installation	If vCenter encounters a problem staging the patches, the vCenter Management Interface displays the **Resume** button. Correct the problem preventing the patches from staging, and click **Resume** to finish staging the patches. The staging process

Option	Description
	resumes from the point at which vCenter encountered the problem.
Revert to last vCenter backup option	Select this option to roll back to the automatically created snapshot. If you choose to revert, a patching rollback API is called. The API checks if a snapshot is available and reverts to the snapshot. **Note:** The automatic creation of a backup is available only when you are patching vCenter 8.0 Update 2 and higher versions.

If you decided to stage the available patches for installation at a later time, you can now install. See Install vCenter Patches.

Configure the Repository for URL-Based Patching

For URL-based patching, by default the vCenter appliance is configured to use the default VMware repository URL that is preset for the build profile of the appliance. You can configure a custom repository URL as the current source of patches for your environment requirements.

Log in to the vCenter Appliance Management Interface as root.

By default the current repository for URL-based patching is the default VMware repository URL.

If vCenter is not connected to the Internet or if your security policy requires it, you can build and configure a custom repository. The custom patching repository runs on a local Web server within your data center and replicates the data from the default repository. Optionally, you can set up an authentication policy for accessing the Web server that hosts the custom patching repository.

1. If you want to configure a custom repository URL, build the repository on your local web server.
2. Log in to the Broadcom Support Portal.
3. Download the vCenter appliance ISO image. See Broadcom knowledge base article 366685.
4. Confirm that the md5sum is correct by using an MD5 checksum tool.
5. On your web server, create a repository directory under the root.

   For example, create the `vc_update_repo` directory.
6. Extract the ZIP file into the repository directory.

   The extracted files are in the `manifest` and `package-pool` subdirectories.
7. In the vCenter Management Interface, click **Update**.
8. Click **Settings**.
9. Select the Repository settings.

Option	Description
Default repository	Uses the default VMware repository URL that is preset for the build profile of the appliance.
Specified repository	Uses a custom repository. You must enter the repository URL, for example, *`https://web_server_name.your_company.com/`*`vc_update_repo`. The repository URL must use a secure protocol such as HTTPS or FTPS.

10. If the specified repository requires authentication, enter the user name and password.
11. (Optional) If you do not want to perform a security certificate check, deselect the **Check Certificate** check box.
    If you trust the URL for the repository, you can choose to bypass the certificate check for the repository URL.
12. Click **OK**.

Install vCenter Patches

Install vCenter Patches

You can check for and can install patches either from an ISO image, directly from a custom repository URL, or from the Broadcom online repository.

- Log in to the vCenter Appliance Management Interface as root.
- Before you can install available patches, you check for new patches and stage the patches to the vCenter appliance. See Check for and Stage Patches to the vCenter Appliance.
- If you are patching the appliance from an ISO image that you previously downloaded from Broadcom Support Portal Downloads, you must attach the ISO image to the CD/DVD drive of the vCenter appliance. You can configure the ISO image as a datastore ISO file for the CD/DVD drive of the appliance by using the vSphere Client. See *vSphere Virtual Machine Administration*.
- If you are patching the appliance from a custom repository URL or from the Broadcom online repository, verify that you have configured the repository settings and that the current repository URL is accessible. See Configure the Repository for URL-Based Patching.
- Create an image-based backup and take a powered-off snapshot of the vCenter Appliance you are patching as a precaution in case there is a failure during the patching process.

  Important:
  The services running in the vCenter appliance become unavailable during the installation of the patches. You must perform this procedure during a maintenance period. As a precaution if there is a failure, you can back up the vCenter. For information on backing up and restoring vCenter, see *vCenter Deployment and Setup*.

1. In the vCenter Management Interface, click **Update**.

   In the **Current version details** pane, you can view the vCenter version and build number.

   In the **Available updates** pane, you can view the available updates with type and release type.

   The **Version** indicates the available version and whether the patch is a quick patch.

   The **Type** indicates the type of the update. The values include:

   - **BUG FIX**
   - **SECURITY**
   - **BUG FIX AND SECURITY**
   - **ENHANCEMENT**
   - **INFORMATIONAL**

   The release type values include the following:

   - **UPDATE**
   - **PATCH**

   The **Reboot Required** indicates if the update requires a reboot of the vCenter system or not, and the values are **Yes** or **No**.

   The **Critical** indicates if the update is critical or not and the values are **Yes** or **No**.

2. Select the range of staged patches to apply and click **Install**.

   Important:
   Some updates might require a reboot of the system. You can see information about these updates in the Available Updates pane.

3. Read and accept the End-User License Agreement.
4. A system pre-check verifies that the patches can be successfully installed with the provided information.

   If the pre-check discovers missing or incorrect information, or other problems preventing a successful installation, you are prompted to correct the problem and resume the installation.
5. After the installation finishes, click **OK**.
6. If the patch installation requires the appliance to reboot, click **Summary**, and click **Reboot** to reset the appliance.

In the Available Updates pane, you can see the changed update status of the vCenter appliance.

Enable Automatic Checks for vCenter Patches

You can configure vCenter to perform automatic checks for available patches in the configured repository URL at a regular interval.

- Log in to the vCenter Appliance Management Interface as root.
- Verify that you have configured the repository settings and that the current repository URL is accessible. See Configure the Repository for URL-Based Patching.

1. In the vCenter Management Interface, click **Update**.
2. Click **Settings**.
3. Select **Check for updates automatically**, and select the day and time in UTC to perform automatic checks for available patches.
4. Click **OK**.

vCenter appliance performs regular checks for available patches in the configured repository URL. In the Available Updates pane, you can view information about the available patches. You can also view the vCenter health status for notifications about available patches. See View Health Status in *vCenter Configuration*.

Patching the vCenter Appliance by Using the Appliance Shell

You can use the `software-packages` utility in the appliance shell of a vCenter appliance to see the installed patches, stage new patches, and install new patches.

To perform ISO-based patching, you download an ISO image, mount the ISO image to the CD/DVD drive of the appliance, optionally stage the available patches from the ISO image to the appliance, and install the patches. For steps to mount the ISO image to the CD/DVD drive, see Configure a Datastore ISO File for the CD/DVD Drive section in the vSphere Virtual Machine Administration.

To perform URL-based patching, you optionally stage the available patches from a repository URL to the appliance and install the patches. The vCenter appliance is preset with a default VMware repository URL for the build profile of the appliance. You can use the `update.set` command to configure the appliance to use the default VMware repository URL or a custom repository URL, for example, a repository URL that you previously built on a local web server running within your data center. You can also use the `proxy.set` command to configure a proxy server for the connection between the vCenter appliance and the repository URL.

View a List of All Installed Patches in the vCenter Appliance

You can use the `software-packages` utility to see a list of the patches currently applied to the vCenter appliance. You can also view the list of the installed patches in chronological order and details about a specific patch.

1. Access the appliance shell and log in as a user who has a super administrator role.

   The default user with a super administrator role is root.
2. To view the full list of patches and software packages installed in the vCenter appliance, run the following command:

   ```
   software-packages list
   ```

3. To view all patches applied to the vCenter appliance in chronological order, run the following command:

   ```
   software-packages list --history
   ```

   You see the list in chronological order. A single patch in this list can be an update of multiple different packages.

4. To view details about a specific patch, run the following command:

   ```
   software-packages list --patch patch_name
   ```

   For example, if you want to view the details about the VMware-vCenter-Server-Appliance-Patch1 patch, run the following command:

   ```
   software-packages list --patch VMware-vCenter-Server-Appliance-Patch1
   ```

   You can see the complete list of details about the patch, such as vendor, description, and installation date.

Configure URL-Based Patching

For URL-based patching, the vCenter appliance is preset with a default VMware repository URL for the build profile of the appliance. You can use the `update.set` command to configure the appliance to use the default or a custom repository URL as the current source of patches and enable automatic checks for patches.

By default the current repository for URL-based patching is the default VMware repository URL.

> **Note:**
> You can use the `proxy.set` command to configure a proxy server for the connection between vCenter and the repository URL. For more information about the API commands in the appliance shell, see *vCenter Configuration*.

If vCenter is not connected to the Internet or if your security policy requires it, you can build and configure a custom repository. The custom patching repository runs on a local Web server within your data center and replicates the data from the default repository. Optionally, you can set up an authentication policy for accessing the Web server that hosts the custom patching repository.

1. Log in to the Broadcom Support Portal.
2. Download the vCenter appliance ISO image. See Broadcom knowledge base article 366685.
3. Confirm that the md5sum is correct by using an MD5 checksum tool.
4. On your web server, create a repository directory under the root.

   For example, create the vc_update_repo directory.

5. Extract the ZIP file into the repository directory.

   The extracted files are in the manifest and package-pool subdirectories.

6. Access the appliance shell and log in as a user who has a super administrator role.

   The default user with a super administrator role is root.

7. To see information about the current URL-based patching settings, run the `update.get` command.

   You can see information about the current repository URL, the default repository URL, the time at which the appliance last checked for patches, the time at which the appliance last installed patches, and the current configuration of automatic checks for patches.

8. Configure the current repository for URL-based patching.

   - To configure the appliance to use the default VMware repository URL, run the following command:

     ```
     update.set --currentURL default
     ```

   - To configure the appliance to use a custom repository URL, run the following command:

     ```
     update.set --currentURL https://web_server_name.your_company.com/vc_update_repo [--username username]
      [--password password]
     ```

     The square brackets [] enclose the command options.

     If the custom repository requires authentication, use the `--username` *`username`* and `--password` *`password`* options.

9. To activate automatic checks for vCenter appliance patches in the current repository URL at regular intervals, run the following command:

   ```
   update.set --CheckUpdates enabled [--day day] [--time HH:MM:SS]
   ```

   The square brackets [] enclose the command options.

   Use the `--day day` option to set the day for performing the regular checks for patches. You can set a particular day of the week, for example, `Monday`, or `Everyday`. The default value is `Everyday`.

   Use the `--time HH:MM:SS` option to set the time in UTC for performing the regular checks for patches. The default value is `00:00:00`.

   The appliance performs regular checks for available patches in the current repository URL.

10. To deactivate automatic checks for vCenter patches, run the following command:

    ```
    update.set --CheckUpdates disabled
    ```

If you configured the appliance to perform automatic checks for available patches, you can regularly view the vCenter appliance health status for notifications about available patches. See View vCenter Health Status in *vCenter Configuration*.

Stage Patches to the vCenter Appliance

Before you install available patches, you can stage the patches to the appliance. You can use the `software-packages` utility to stage patches either from a local repository by attaching an ISO image to the appliance, or from a remote repository directly by using a repository URL.

- If you are staging patches from an ISO image that you previously downloaded from the Broadcom Support Portal, you must attach the ISO image to the CD/DVD drive of the vCenter appliance. You can configure the ISO image as a datastore ISO file for the CD/DVD drive of the appliance by using the vSphere Client. See *vSphere Virtual Machine Administration*.
- If you are staging patches from a remote repository, verify that you have configured the repository settings and that the current repository URL is accessible. See Configure URL-Based Patching.

1. Access the appliance shell and log in as a user who has a super administrator role.

   The default user with a super administrator role is root.

2. Stage the patches.

   - To stage the patches included in the attached ISO image, run the following command:

     ```
     software-packages stage --iso
     ```

   - To stage the patches included in the current repository URL, run the following command:

     ```
     software-packages stage --url
     ```

     By default the current repository URL is the default VMware repository URL.

     If you want to stage only the third-party patches, use the `--thirdParty` option.

   - To stage the patches included in a repository URL that is not currently configured in the appliance, run the following command:

     ```
     software-packages stage --url URL_of_the_repository
     ```

     If you want to stage only the third-party patches, use the `--thirdParty` option.

   If you want to directly accept the End-User License Agreement, use the `--acceptEulas` option.

   For example, to stage only the third-party patches from the current repository URL with directly accepting the End-User License Agreement, run the following command:

   ```
   software-packages stage --url --thirdParty --acceptEulas
   ```

   In the process of staging, the command validates that a patch is a VMware patch, that the staging area has enough free space, and that the patches are not altered. Only completely new patches or patches for existing packages that can be upgraded are staged.

3. Optional: To see information about the staged patches, run the following command:

   ```
   software-packages list --staged
   ```

   Each patch includes a metadata file that contains information such as patch version, product name, whether a restart of the system is required, and so on.

4. Optional: To view a list of the staged patches, run the following command:

   ```
   software-packages list --staged --verbose
   ```

5. Optional: To unstage the staged patches, run the following command:

   ```
   software-packages unstage
   ```

   All directories and files generated by the staging process are removed.

Install the staged patches. See Install vCenter Patches.

Important:
If you staged the patches from an ISO image, keep the ISO image attached to the CD/DVD drive of the appliance. The ISO image must be attached to the CD/DVD drive of the appliance throughout the staging and installation processes.

Install vCenter Patches

You can use the `software-packages` utility to install the staged patches. You can also use the `software-packages` utility to install patches directly from an attached ISO image or repository URL without staging the patch payload.

- If you are installing staged patches, verify that you staged the correct patch payload. See Stage Patches to the vCenter Appliance.
- If you are installing patches that you previously staged from an ISO image, verify that the ISO image is attached to the CD/DVD drive of the vCenter appliance. See Stage Patches to the vCenter Appliance.
- If you are installing patches directly from an ISO image that you previously downloaded from the Broadcom Support Portal, you must attach the ISO image to the CD/DVD drive of the vCenter appliance. You can configure the ISO image as a datastore ISO file for the CD/DVD drive of the appliance by using the vSphere Client. See Change the CD/DVD Drive Configuration in *vSphere Virtual Machine Administration*.
- If you are installing patches directly from a repository, verify that you have configured the repository settings and that the current repository URL is accessible. See Configure URL-Based Patching.
- Create an image-based backup and take a powered-off snapshot of the vCenter appliance you are patching as a precaution in case there is a failure during the patching process.

Important:

The services running in the appliance become unavailable during the installation of the patches. You must perform this procedure during a maintenance period. As a precaution in case of failure, you can back up the vCenter appliance. For information about backing up and restoring vCenter, see File-Based Backup and Restore of vCenter and Image-Based Backup and Restore of a vCenter Environment in *vCenter Deployment and Setup*.

1. Access the appliance shell and log in as a user who has a super administrator role.

   The default user with a super administrator role is root.

2. Install the patches.

   - To install staged patches, run the following command:

     ```
     software-packages install --staged
     ```

   - To install patches directly from an attached ISO image, run the following command:

     ```
     software-packages install --iso
     ```

   - To install patches directly from the current repository URL, run the following command:

     ```
     software-packages install --url
     ```

     By default the current repository URL is the default VMware repository URL.

   - To install patches directly from a repository URL that is not currently configured, run the following command:

```
software-packages install --url URL_of_the_repository
```

If you want to directly accept the End-User License Agreement, use the `--acceptEulas` option.

For example, to install patches from the current repository URL without staging the patches with directly accepting the End-User License Agreement, run the following command:

```
software-packages install --url --acceptEulas
```

3. If the patch installation requires a reboot of the appliance, run the following command to reset the appliance.

```
shutdown now -r "patch reboot"
```

Patching a vCenter High Availability Environment

To patch a vCenter appliance configured in a vCenter High Availability (HA) cluster, you must remove the vCenter High Availability configuration and delete the Passive and Witness nodes. After patching the vCenter appliance, you must re-create your vCenter High Availability clusters.

This procedure describes how to remove the vCenter HA configuration.

1. In the vSphere Client, log in to the vCenter from which you want to remove the vCenter HA configuration.
2. Click the **Configure** tab, and select vCenter **HA**.
3. Select **Remove vCenter HA** .
   - The vCenter HA cluster's configuration is removed from the Active, Passive, and Witness nodes.
   - The Active node continues to run as a standalone vCenter appliance.
4. Delete the Passive and Witness nodes.

Patch the vCenter appliance as described in either Patching vCenter Using the vCenter Management Interface or Patching the vCenter Appliance by Using the Appliance Shell.

After patching the vCenter appliance, you can configure vCenter HA. For information about configuring vCenter HA, see You Can Minimize Downtime with vSphere in *vSphere Availability*.

Troubleshooting vCenter Upgrade

The installation and upgrade software enables you to identify problems on the client machine that can cause an installation, upgrade, or migration to fail.

For interactive installations, upgrades, and migrations, the errors or warnings are displayed on the final panel of the installer, where you are asked to confirm or cancel the installation or upgrade. For scripted installations, upgrades, or migrations, the errors or warnings are written to the installation log file. You can also consult the product release notes for known problems.

vSphere Update Manager provides custom messages for these errors or warnings. To see the original errors and warnings that are returned by the precheck script during an Update Manager host upgrade scan, review the Update Manager log file `vmware-vum-server-log4cpp.log`.

The *vSphere Upgrade* guide describes how to use VMware products and their features. If you encounter problems or error situations that are not described in this guide, you may find a solution in the Broadcom Support Portal. You can also use Broadcom Community Forums to find others with the same problem or ask for help, or you can open Support Request to get help from a VMware service professional.

- Export a vCenter Support Bundle for Troubleshooting

Errors and Warnings Returned by the Installation and Upgrade Precheck Script

The installation and upgrade precheck script runs tests to identify problems on the host machine that can cause an installation, upgrade, or migration to fail.

For interactive installations, upgrades, and migrations, the errors or warnings are displayed on the final screen of the GUI installer, where you are asked to confirm or cancel the installation or upgrade. For scripted installations, upgrades, or migrations, the errors and warnings are written to the installation log file.

vSphere Update Manager provides custom messages for these errors or warnings. To see the original errors and warnings returned by the precheck script during an Update Manager host upgrade scan, review the Update Manager log file `vmware-vum-server-log4cpp.log`.

Table 64: Error and Warning Codes That Are Returned by the Installation and Upgrade Precheck Script

Error or Warning	Description
64BIT_LONGMODESTATUS	The host processor must be 64-bit.
COS_NETWORKING	Warning. An IPv4 address was found on an enabled service console virtual NIC that has no corresponding address in the same subnet in the VMkernel. A separate warning appears for each such occurrence.
CPU_CORES	The host must have at least two cores.
HARDWARE_VIRTUALIZATION	Warning. If the host processor does not have hardware virtualization, or if hardware virtualization is not turned on in the host BIOS, host performance reduces. You can enable hardware virtualization in the host machine boot options panel. See your hardware vendor's documentation.
MD5_ROOT_PASSWORD	This test checks that the root password is encoded in MD5 format. If a password is not encoded in MD5 format, it might be significant only to eight characters. In this case, any characters after the first eight are no longer authenticated after the upgrade, which can create a security problem.
MEMORY_SIZE	The host requires the specified amount of memory to upgrade.
PACKAGE_COMPLIANCE	vSphere Update Manager upgrade to vSphere Lifecycle Manager only. This test checks the existing software on the host against the software contained on the upgrade ISO to determine whether the host has been successfully upgraded. If any of the packages are missing or are an older version than the package on the upgrade ISO, the test returns an error. The test results indicate which software was found on the host and which software was found on the upgrade ISO.
PARTITION_LAYOUT	You can upgrade or migrate software only if at most one VMFS partition on the disk is being upgraded. The VMFS partition must begin after sector 1843200.
POWERPATH	This test checks for the installation of EMC PowerPath software, consisting of a CIM module and a kernel module. If either of these components is found on the host, the test checks that matching components, such as CIM or the VMkernel and module, also exist in the upgrade. If they do not exist, the test returns a warning that indicates which PowerPath components were expected on the upgrade ISO and which, if any, were found.
PRECHECK_INITIALIZE	This test checks that the precheck script can be run.
SANE_ESX_CONF	The `/etc/vmware/esx.conf` file must exist on the host.
SPACE_AVAIL_ISO	vSphere Update Manager only. The host disk must have enough free space to store the contents of the installer CD or DVD.
SPACE_AVAIL_CONFIG	vSphere Update Manager upgrade to vSphere Lifecycle Manager only. The host disk must have enough free space to store the legacy configuration between reboots.
SUPPORTED_ESX_VERSION	You can upgrade to ESX9.0 only from version 8.0 ESX hosts.
TBOOT_REQUIRED	This message applies only to vSphere Update Manager upgrade to vSphere Lifecycle Manager only. The upgrade fails with this error when the host system is running in trusted boot mode (tboot), but the ESX upgrade ISO does not contain any tboot VIBs. This test prevents an upgrade that can make the host less secure.
UNSUPPORTED_DEVICES	Warning. This test checks for unsupported devices. Some PCI devices are not supported in ESX9.0.

Error or Warning	Description
UPDATE_PENDING	This test checks the host for VIB installations that require a reboot. This test fails if one or more such VIBs are installed, but the host has not yet been rebooted. In these conditions, the precheck script is unable to determine reliably which packages are currently installed on the host. If this test fails, it may not be safe to rely on the rest of the precheck tests to determine whether an upgrade is safe. If you encounter this error, restart the host and retry the upgrade.

Upgrade Issues with vCenter Containing Host Profiles

Most common issues that might occur during a vCenter upgrade to version 9.1, that contains host profiles.

- For issues occurring during a vCenter upgrade or ESX upgrade, see Troubleshooting vSphere Host Profiles in *vSphere Host Profiles*
- If an error occurs when you import a host profile to an empty vCenter inventory, see Reference Host is Unavailable in *vSphere Host Profiles* for Reference Host is Unavailable.
- If a host profile compliance check fails for NFS datastore, see vSphere Host Profile without an NFS Datastore in *vSphere Host Profiles*.

vCenter Configuration

vCenter Configuration provides information about configuring VMware vCenter®.

Intended Audience

This information is intended for anyone who wants to configure VMware vCenter®. The information is written for experienced system administrators who are familiar with virtual machine technology and data center operations.

At VMware, we value inclusion. To foster this principle within our customer, partner, and internal community, we create content using inclusive language.

vSphere Client and vCenter Management Interface

Instructions in this guide reflect the vSphere Client, an HTML5-based GUI, and the vCenter Management Interface. Some additional functions can be performed using the vCenter appliance shell and the Direct Console User Interface.

How to Configure vCenter

You deploy the vCenter appliance as a preconfigured virtual machine optimized for running vCenter and associated services.

During the deployment of vCenter, you can create a vCenter Single Sign-On domain or join an existing domain. For information about the vCenter deployment, see Introduction to vSphere Deployment and Setupin the *vCenter Deployment and Setup* documentation.

The vCenter appliance package contains the following software:

- Photon OS® 5.0
- The vSphere authentication services
- PostgreSQL
- VMware vSphere Lifecycle Manager Extension
- VMware vCenter Lifecycle Manager

Customization of the preconfigured virtual machine is unsupported except for adding memory, CPU, and disk space.

vCenter has the following default user names:

- root user with the password that you set during the deployment of the appliance. You use the root user to log in to the vCenter Appliance Management Interface and to the preconfigured virtual machine operating system.

  Important:
  The password for the root account of vCenter expires after 90 days by default. For information about changing the root password and configuring the password expiration settings, see Change the Password and Password Expiration Settings of the Root User.
- administrator@*your_domain_name* which is the vCenter Single Sign-On user with the password and domain name that you set during the deployment of the appliance.

  When you install vCenter, you can change the vSphere domain. Do not use the same domain name as the domain name of your Microsoft Entra ID domain name.

  Initially, only the user administrator@*your_domain_name* has the privileges to log in to the vCenter system. By default, the administrator@*your_domain_name* user is a member of the **SystemConfiguration** > **Administrators** group. This user can add an identity source in which additional users and groups are defined to vCenter Single Sign-On or give permissions to the users and groups. For more information, see *vSphere Authentication*and *vSphere Security*.

You can configure vCenter settings in four ways:

- Use the vCenter Management Interface.

  You can edit the system settings such as access, network, time synchronization, and the root password settings. This is the preferred way for configuring vCenter.

- Use the vSphere Client.
  You can navigate to the system configuration settings of vCenter and configure the deployment to an external identity provider domain. You can manage the services that are running in vCenter and modify various settings such as access, network, and firewall settings.
- Use the Bash shell.
  You can use TTY1 to log in to the console or can use SSH and run configuration, monitoring, and troubleshooting commands in vCenter.
- Use the Direct Console User Interface.
  You can use TTY2 to log in to the vCenter Direct Console User Interface to change the password of the root user, configure the network settings, or enable access to the Bash shell or SSH.

Using the vCenter Management Interface to Configure vCenter

After you deploy vCenter, you can log in to the vCenter Management Interface and edit the settings.

For information about patching vCenter and enabling automatic checks for vCenter patches, see Patching and Updating vCenter 9.1 Deployments in the *vCenter Upgrade* documentation.

For information backing up and restoring vCenter, see File-Based Backup and Restore of vCenterin the *vCenter Deployment and Setup* documentation.

Log In to the vCenter Appliance Management Interface

Log in to the vCenter Appliance Management Interface to access the vCenter configuration settings.

Verify that the vCenter is successfully deployed and running.

> **Note:**
> The login session expires if you leave the vCenter Appliance Management Interface idle for 10 minutes.

1. In a web browser, go to the vCenter Appliance Management Interface, https://*`appliance-IP-address-or-FQDN`*:5480.
2. Log in as root.
   The default root password is the password that you set while deploying vCenter.

View vCenter Health Status

You can use the vCenter Management Interface to view the overall health status of vCenter and health messages.

Log in to the vCenter Appliance Management Interface as root.

The overall health status of vCenter is based on the status of the hardware components such as CPU, memory, database, storage, and swap. It is also based on the update component, which shows whether the software packages are up to date according to the last check for available patches.

> **Important:**
>
> If you do not perform regular checks for available patches, the health status of the update component might become out-of-date. For information about how to check for vCenter patches and enable automatic checks for vCenter patches, see Patching and Updating vCenter 9.1 Deployments in the *vCenter Upgrade* documentation.

1. In the vCenter Management Interface, click **Summary**.
2. In the Health Status pane, view the Overall Health badge.

Table 65: Health Status

Badge Icon	Description
	Good. All components are healthy.
	Warning. One or more components might become overloaded soon. View the details in the Health Messages pane.
	Alert. One or more components might be degraded. Nonsecurity patches might be available. View the details in the Health Messages pane.
	Critical. One or more components might be in an unusable status and vCenter might become unresponsive soon. Security patches might be available. View the details in the Health Messages pane.
	Unknown. No data is available.

Reboot or Shut Down vCenter

You can use the vCenter Appliance Management Interface to restart or power off the virtual machine running.

Log in to the vCenter Appliance Management Interface as root.

1. From the top menu pane, click the **Actions** drop-down menu.
2. Click **Reboot** or **Shutdown** to restart or power off the virtual machine.
3. In the confirmation dialog box, click **Yes** to confirm the operation.

Create a Support Bundle

You can create a support bundle that contains the log files for the vCenter instance running in the appliance. You can analyze the logs locally on your machine or can send the bundle to Broadcom Support.

Log in to the vCenter Appliance Management Interface as root.

1. Navigate to the **Create Support Bundle** option.
   a) From the header navigation, click the **Actions** drop-down menu.
   b) Click **Monitor** from the vertical navigation and select the **Logs** tab.
2. Click **Create Support Bundle**.
3. Select the components that you require the logs for.
4. Add a description and click **SAVE**.

   The created support bundle appears in the table on the **Monitor** > **Logs** tab.
5. Select the support bundle from the list and click **DOWNLOAD**.
6. Delete the bundle after you download it.

   Note:

   Generated support bundles are stored temporarily on the system. If you do not manually delete a support bundle after downloading it, the system automatically deletes it after 12 hours by default to preserve storage space. Ensure that you download the bundle before it expires.

The support bundle is downloaded as a `.tgz` file on your local machine.

Monitor CPU and Memory Use

You can use the vCenter Appliance Management Interface to monitor the overall CPU and memory use of vCenter.

Log in to the vCenter Appliance Management Interface as root.

1. In the vCenter Appliance Management Interface, click **Monitor**.
2. On the Monitor page, click the **CPU & Memory** tab.
3. From the **date range** drop-down menu, select the time period for which you want to generate a CPU utilization trending graph and a memory utilization trending graph.
4. Point to the graphs to see the CPU and memory use for a particular date and time.

Monitor Disk Use

You can use the vCenter Appliance Management Interface to monitor the disk use of vCenter.

Log in to the vCenter Appliance Management Interface as root.

1. In the vCenter Management Interface, click **Monitor**.
2. On the Monitor page, click the **Disks** tab.

The Monitor Disks pane shows a disk, sortable by name, partition, or utilization.

Monitor Network Use

You can use the vCenter Appliance Management Interface to monitor the network use of vCenter in the last day, week, month, or quarter.

Log in to the vCenter Appliance Management Interface as root.

1. In the vCenter Appliance Management Interface, click **Monitor**.
2. On the Monitor page, click the **Network** tab.
3. From the **date range** drop-down menu, select the time period for generating the network utilization graph.
4. From the table below the graph grid, select a packet or transmit byte rate to monitor.
   The options vary depending on your network settings.
   The network utilization graph refreshes to display the use of the item you select.
5. Point to the network utilization graph to see the network use data for a particular date and time.

Monitor Database Use

You can use the vCenter Appliance Management Interface to monitor the use of the embedded database of the vCenter by data type. You can also monitor space use trending graphs and filter any of the largest data types.

Log in to the vCenter Appliance Management Interface as root.

1. In the vCenter Appliance Management Interface, click **Monitor**.
2. On the Monitor page, click the **Database** tab to monitor the consumed and free space for the vCenter database.
3. From the **date range** drop-down menu, select the time period for which you want to generate the space utilization trending graphs.
4. At the base of the graph, click the title a particular database component to include or exclude that component from the graph.

Option	Description
Seat space utilization trend graph	Allows you to select and view alarm, event, task, and stat trendlines.
Overall space utilization trend graph	Allows you to select and view SEAT, DB Log, and core trendlines.

5. Point to the space utilization graph to see the database use value for a particular date and time.

Enable or Disable SSH and Bash Shell Access

You can use the vCenter Appliance Management Interface to edit the access settings for the appliance.

Log in to the vCenter Appliance Management Interface as root.

You can enable or disable an SSH administrator login to the appliance. You can also enable access to the vCenter Bash shell for a specific time interval.

1. In the vCenter Management Interface, click **Access**, and click **Edit**.
2. Edit the access settings for vCenter.

Option	Description
Activate SSH login	Activates SSH access to vCenter.
Activate DCUI	Activates DCUI access to vCenter.
Activate Console CLI	Activates console CLI access to vCenter.
Activate Bash Shell	Activates Bash shell access to vCenter for the number of minutes that you enter.

3. Click **OK** to save the settings.

Configure the DNS, IP Address, and Proxy Settings

You can set the combination of static and DHCP, IPv4 and IPv6 addresses, edit the DNS settings, and define the proxy settings for vCenter.

- To change the IP address of the appliance, verify that the system name of the appliance is an FQDN. The system name is used as a primary network identifier. If you set an IP address as a system name during the deployment of the appliance, you can later change the PNID to an FQDN.

  Note:
  You can set only IPv4 IP address as system name. The IPv4 IP address must be enabled before this setting.
- To restore a dual stack VC, the base VC after stage 1 deployment should be configured as:
  - If PNID of backed up VC resolves to IPv4 and IPv4 is configured static, the base VC during stage1 should have static or DHCP IPv4 configured.
  - If PNID of backed up VC resolves to IPv4 and IPv4 is configured DHCP, the base VC during stage1 should have DHCP IPv4 configured.
  - If PNID of backed up VC resolves to IPv6 and IPv6 is configured static, the base VC during stage1 should have static or DHCP IPv6 configured.
  - If PNID of backed up VC resolves to IPv6 and IPv6 is configured DHCP, the base VC during stage1 should have DHCP IPv6 configured.
- Log in to the vCenter Appliance Management Interface as root.

1. In the vCenter Appliance Management Interface, click **Networking**.
2. From the Network Settings page, click **Edit**.
3. Select **Network Adapter** and click **NEXT**.
4. Expand the Hostname and DNS section to configure the DNS settings.

   Note:
   Valid value for Hostname is either FQDN resolving to enabled IP address or IPv4 IP address.

Option	Description
Obtain DNS settings automatically	Obtains the DNS settings automatically from the network.
Enter DNS settings manually	Lets you set the DNS address settings manually. If you select this option, you must provide the following information: • The IP address of the preferred DNS server. • The IP address of the alternate DNS server.

5. Expand the NIC 0 section to configure the gateway settings.

   Note:
   PNID and network APIs support only NIC 0 as primary NIC.

   Recommended steps to configure network other than NIC 0, when vCenter has multiple NICs configured are:

   - NIC 1 is reserved for VCHA and should not be used in multi-NIC configurations.
   - As mentioned in the UI specifications, DGW should be set to NIC 0.
   - As access to vSphere Client is redirected to PNID, only access to NIC 0 is supported or recommended even in multi-NIC configurations.

6. Edit the IPv4 address settings.

Option	Description
Activate or Deactivate IPv4 settings	Activates or deactivates the IPv4 address based on the toggle switch option.
Obtain IPv4 settings automatically	Obtains the IPv4 address for the appliance automatically from the network.
Enter IPv4 settings manually	Uses an IPv4 address that you set manually. You must enter the IP address, subnet prefix length, and the default gateway. **Note:** For static IPv4 or IPv6 addresses, DNS server must be set manually.

   Note:
   Second and third party solutions need to re-register, when there is a change in the IPv4 and IPv6 IP addressess.

7. Edit the IPv6 address settings.

Option	Description
Enable or Disable IPv6 settings	Enables or disables the IPv6 address based on the toggle switch option.
Obtain IPv6 settings automatically through DHCP	Assigns IPv6 addresses to the appliance automatically from the network by using DHCP.
Obtain IPv6 settings automatically through router advertisement	Assigns IPv6 addresses to the appliance automatically from the network by using router advertisement.
Use static IPv6 addresses	Uses static IPv6 addresses that you set up manually. 1. Click the checkbox. 2. Enter the IPv6 address and the subnet prefix length. 3. Click **Add** to enter additional IPv6 addresses. 4. Click **Save**. **Note:** For static IPv4 or IPv6 addresses, DNS server must be set manually.

   You can configure the appliance to obtain the IPv6 settings automatically through both DHCP and router advertisement. You can assign a static IPv6 address at the same time.

   Note:
   Second and third-party solutions must re-register when there is a change in the IPv4 and IPv6 IP addresses.

8. In **SSO credentials**, enter the SSO administrator credentials for vCenter and Click **NEXT**.
9. Review and save the networking configuration.
10. To configure a proxy server, in the Proxy Settings section of the the Network Settings page, click **Edit**.
11. Select the proxy setting to activate.

Option	Description
FTP	Activate to configure the FTP proxy settings. **Note:** Ensure that the ICMP is enabled on the proxy server.
HTTPS	Activate to configure the HTTPS proxy settings.
HTTP	Activate to configure the HTTP proxy settings.

12. Optional: To add proxy bypass list entries, enter the IPv4 addresses, FQDNs, or domain names that you want to bypass as a comma separated list.
13. Enter the server hostname or IP address.
14. Enter the port.
15. Enter the username (optional).
16. Enter the password (optional).
17. Click **Save**.

Reconfigure the Primary Network Identifier

You can change the FQDN, IP, or PNID of the management network of vCenter.

Log in to the vCenter Appliance Management Interface as root.

The system name is used as a primary network identifier. If you set an IP address as a system name during the deployment of the appliance, you can later change the PNID to an FQDN. You cannot change an FQDN back to an IP address.

Note:

If vCenter High Availability (HA) is enabled, you must deactivate the vCenter HA setup before reconfiguring the PNID.

1. In the vCenter Appliance Management Interface, navigate to the **Networking** page and click **Edit**.
2. Select the NIC to be modified and click **Next**.
3. In the **Edit Settings** pane, change the host name and provide the new IP address. Click **Next**.
4. In the **SSO Credentials** pane, provide the administrator SSO credentials. You must use `administrator@<domain_name>` credentials.
5. In the **Ready to Complete** pane, review your new settings and check the backup acknowledgment box. Click **Finish**.

   A taskbar shows the status of the network update. To cancel the update, click **Cancel Network Update**. When the network reconfiguration is complete, the UI redirects to the new IP address.
6. To finish the reconfiguration process and restart services, log in using your administrator SSO credentials.
7. On the **Networking** page, verify the new host name and IP address.

- Re-register all deployed plug-ins.
- Regenerate all custom certificates.
- If vCenter HA was enabled, reconfigure vCenter HA.
- If Active Domain was enabled, reconfigure Active Domain.
- If Hybrid Link mode was enabled, reconfigure Hybrid Link with the Cloud vCenter.

Edit the Firewall Settings

After you deploy vCenter, you can edit its firewall settings and create firewall rules using the Management Interface.

Verify that the user who logs in to the vCenter instance is a member of the `SystemConfiguration.Administrators` group in vCenter Single Sign-On.

You can set up firewall rules to accept or block traffic between vCenter and specific servers, hosts, or virtual machines. You cannot block specific ports, you block all the traffic.

1. In the vCenter Appliance Management Interface, click **Firewall**.
2. Edit the firewall settings.

Command	Action
Add	1. To create a firewall rule, click **Add**. 2. Select a network interface of the virtual machine. 3. Enter the IP address of the network to apply this rule to. The IP address can be IPv4 and IPv6 address. 4. Enter a subnet prefix length. If you only block one IP address, use a 32-bit subnet mask. 5. From the **Action** drop-down menu, select whether to **Accept**, **Ignore**, **Reject**, or **Return** the connection between vCenter and the network that you entered. 6. Click **Save**.
Edit	1. Select a rule and click **Edit**. 2. Edit the settings of the rule. 3. Click **Save**.
Delete	1. Select a rule and click **Delete**. 2. At the prompt, click **Delete** again.
Reorder	1. Select a rule and click **Reorder**. 2. In the **Reorder** pane, select the rule to move. 3. Click **Move Up** or **Move Down**. 4. Click **Save**.

Configure the System Time Zone and Time Synchronization Settings

After you deploy vCenter, you can change the system time zone and time synchronization settings from the vCenter Appliance Management Interface.

Log in to the vCenter Appliance Management Interface as root.

When you deploy vCenter, you either use the time settings of the ESX host on which vCenter is running or you configure the time synchronization using an NTP server. If the time settings in your vSphere network change, you can edit the time zone and time synchronization settings in the appliance.

1. In the vCenter Appliance Management Interface, click **Time**.
2. Configure the system time zone settings.
   a) In the Time zone pane, click **Edit**.
   b) From the **Time zone** drop-down menu, select a location or time zone and click **Save**.
3. Configure the time synchronization settings.
   a) In the Time synchronization pane, click **Edit**.
   b) From the **Mode** drop-down menu, configure the time synchronization method.

Option	Description
Disabled	No time synchronization. Uses the system time zone settings.
Host	Enables VMware Tools time synchronization. Uses VMware Tools to synchronize the time of the appliance with the time of the ESX host.
NTP	Enables NTP synchronization. You must enter the IP address or FQDN of one or more NTP servers.

   c) Click **Save**.

Start, Stop, and Restart Services

You can use the vCenter Appliance Management Interface to view the status of vCenter components and to start, stop, and restart services.

Log in to the vCenter Appliance Management Interface as root.

You can use the `vimtop` utility plug-in to monitor vSphere services that run in the vCenter instance. See Using the vimtop Plug-In to Monitor the Resource Use of Services.

1. In the vCenter Appliance Management Interface, click **Services**.
   The Services page displays a table of the installed services that can be sorted by name, startup type, health, and state.
2. Select a service and click **SET STARTUP TYPE** to configure either Manual or Automatic start of a service.
3. Select a service and click **START** to start a service.
4. Select a service and click **STOP** to stop, or **RESTART** to restart a service, then click **OK**.

   Warning:
   Stopping or Restarting some services may lead to functionality becoming temporarily unavailable.

Configure Update Settings

You can use the vCenter Appliance Management Interface to configure your update settings and check for new updates.

Log in to the vCenter Appliance Management Interface as root.

1. In the vCenter Appliance Management Interface, click **Update**.
2. To configure your update settings, click **Settings**.
   a) To check for updates automatically, select the checkbox.
   b) Select to use a default or custom repository.
   c) If you selected a custom repository, enter the repository URL, username (optional), and password (optional). Click **Save**.
   For the URL, HTTPS and FTPS protocols are supported.
3. To manually check for updates, click the **Check Updates** drop-down menu.
   a) Select to check a **CD-ROM** or a **CD-ROM + URL** for updates.

The Available Updates table displays available updates sortable by version, type, release date, reboot requirement, and severity.

Change the Password and Password Expiration Settings of the Root User

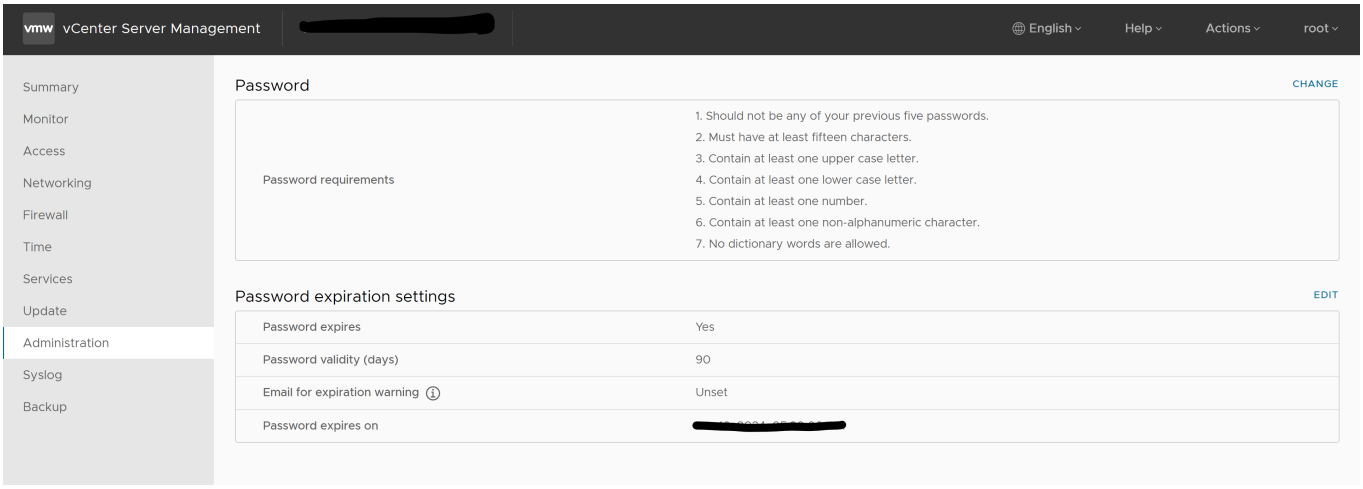
When you deploy vCenter, you set the initial password of the root user, which expires after 90 days by default. You can change the root password and the password expiration settings from the vCenter Appliance Management Interface.

Log in to the vCenter Appliance Management Interface as root.

1. In the vCenter Appliance Management Interface, click **Administration**.
2. In the Password section, click **Change**.
3. Enter the current password and the new password, then click **Save**.
4. Configure the password expiration settings for the root user.
   a) In the Password expiration settings section, click **Edit** and select the password expiration policy.

Option	Description
Yes	The password of the root user expires after a specified number of days. You must provide the following information: • **Root password validity (days)** The number of days after which the password expires. • **Email for expiration warning** The email address to which vCenter sends a warning message before the expiration date.
No	The password of the root user never expires.

   b) In the Password expiration settings pane, click **Save** to apply the new password expiration settings.



The Password expiration settings section displays the new expiration date.

Forward vCenter Log Files to Remote Syslog Server

You can forward the vCenter log files to a remote syslog server to conduct an analysis of your logs.

Log in to the vCenter Appliance Management Interface as root.

Note:

ESX can be configured to send log files to a vCenter rather than storing them to a local disk. The recommended maximum numbers of supported hosts to collect logs from is 30. See Broadcom knowledge base article 318939 for information on how to configure ESX log forwarding. This feature is intended for smaller environments with stateless ESX hosts. For all other cases, use a dedicated log server. Using vCenter to receive ESX log files might impact vCenter performance.

1. In the vCenter Appliance Management Interface, select **Syslog**.
2. In the Forwarding Configuration section, click **Configure** if you have not configured any remote syslog hosts. Click **Edit** if you already have configured hosts.
3. In the Create Forwarding Configuration pane, enter the server address of the destination host. The maximum number of supported destination hosts is three.
4. From the **Protocol** drop-down menu, select the protocol to use.

Menu Item	Description
TLS	Transport Layer Security
TCP	Transmission Control Protocol
RELP	Reliable Event Logging Protocol
UDP	User Datagram Protocol

5. In the **Port** text box, enter the port number to use for communication with the destination host.
6. In the Create Forwarding Configuration pane, click **Add** to enter another remote syslog server.
7. Click **Save**.
8. Verify that the remote syslog server is receiving messages.
9. In the Forwarding Configuration section, click **Send Test Message.**
10. Verify on the remote syslog server that the test message was received.
    The new configuration settings are shown in the Forwarding Configuration section.
11. Optional: To view the logs that are exported, log in to the vCenter Appliance Management Interface as root user and view the list of log files in `/etc/vmware-syslog/` directory.

Configure Log Insight Agent to Send Custom vCenter Logs to Log Management

You can configure the Log insight Agent service to collect and send custom vCenter logs to log management.

In vCenter 9.1, the Log insight Agent service is added as part of the vCenter appliance and is deactivated by default. When you configure the Log Insight Agent service, the service is started automatically.

If you installed and configured the Log Insight Agent on your vCenter system before upgrading to version 9.1, your configuration settings are not preserved and you must reconfigure the service.

1. On the vSphere Client home page, click **Developer Center** and select the **API Explorer** tab.
2. From the **Select Endpoint** drop-down menu, select a vCenter instance from your environment.
3. From the **Select API** drop-down menu, select `appliance`.
4. Locate the **logging/liagent/log_collection** API category and expand the `PUT` method.
5. Under **Try it out**, in the **request_body**, enter the following information:

```
{
    "configurations": [ {
        "enabled": true,
        "certificates": [ "-----BEGIN CERTIFICATE-----\n...\n-----END CERTIFICATE-----" ],
        "content": "<raw_string_li_agent_configuration>",
        "host": "<li_agent_server_host_name>",
        "loglevel": "<desired_log_level>",
        "port": 9543,
        "protocol": "cfapi",
        "unitid": "",
        "unittype": "VCENTER"
    } ]
}
```

The `ApplianceLoggingLiagentLogCollectionSet` is the data structure that is used by Log Insight Agent service to configure the collection of logs from a vCenter system or ESX hosts and send them to log management.

When building your request payload, populate the following fields:

Field	Data types	Description
`enabled`	boolean	**Required**. Specifies whether log collection is enabled for the component that is specified with `unittype` field. Possible values are `true` and `false`.
`unitid`	String	**Required**. A unique identifier for the log collection unit, typically aligned with the logical or infrastructure identity of the component. Allows component granularity in complex environments, for example, the hostname or FQDN.
`unittype`	String	**Required**. Defines the possible unit types for vCenter server. Possible values are `VCENTER` and `ESX`.
`content`	String	**Required**. Specify the configuration of the log collector agent as a raw string by using the INI format. For example, `"\n[server]\nhostname=<fqdn_vcf_ops_for_logs>\nproto=cfapi \nport=9543\n[update]\nauto_update=0\n[filelog|vsphere8_0-linux-applmgmt]\ndirectory=/var/log/vmware/applmgmt \ninclude=\"*.log*\";\"\"\nexclude=\"*.gz;*.stderr;*.stdout \"\ntags={\"vmw_product\": \"vcenter\"}"`
`host`	String	Specify the host name of the log management server.
`port`	integer	Enter the port on the log management server to which you want to send log traffic. The value of this field is used with the `host` field to fully identify the destination endpoint for the collected logs.
`protocol`	String	Define the protocol that is used to forward logs to the log managementserver. Currently, the supported values are `cfapi` and `syslog`.
`certificates`	Array<String>	Provide a list of PEM-encoded (Privacy-Enhanced Mail) certificates where each string represents a single certificate. These certificates are used to establish a secure connection between the component, for example, vCenter, and the log management server.
`loglevel`	String	**Optional**. Enter the desired overall log verbosity for the component. Supported log levels are: `info`, `debug`, `verbose`, `warning`, and `error`. If unset, the `loglevel` value is taken from the `content` payload. For the `VCENTER`component this field is not applicable.

6. Click **Execute** to configure the Log insight Agent.

Your configuration is preserved when you update or upgrade your vCenter system.

You must configure log collection in log management for your vCenter. See the *Configuring and Analyzing Logs* chapter in the *Infrastructure Operations* section of the *VMware Cloud Foundation* documentation.

Configure and Schedule Backups

You can use the vCenter Appliance Management Interface to set a backup location, create a backup schedule, and monitor backup activity.

Log in to the vCenter Appliance Management Interface as root.

1. In the vCenter Appliance Management Interface, click **Backup**.
2. To create a backup schedule, click **Configure**. To edit an existing backup schedule, click **Edit**.
   a) In the **Backup Schedule** pane, enter the backup location using the format `protocol://server-address<:port-number>/folder/subfolder`.
   Supported protocols for backup are FTPS, HTTPS, SFTP, FTP, NFS, SMB, and HTTP.

b) Enter the username and password for the backup server.
c) Enter the time and frequency for the backup to occur.
d) (Optional) Enter an encryption password for the backup.
e) Indicate the number of backups to retain.
f) Indicate the types of data to be backed up.

3. To initiate a manual backup, click **Backup Now**.

Information for scheduled and manual backups is displayed in the **Activity** table.

Using the vSphere Client to Configure vCenter

You can perform some configuration operations from the vSphere Client such as configuring vCenter Identity Provider Federation, networking, and other settings.

Configuring vCenter

You can configure vCenter from the vSphere Client and from the vCenter Appliance Management Interface.

What you can do depends on your deployment.

You can change many of the vCenter settings, including statistics collection, logging, and more.

Configuring Statistics Settings

To set up how statistical data is recorded, you configure collection intervals for statistics. You can access the stored statistical information through command-line monitoring utilities or by viewing performance charts in the vSphere Client.

Configure Statistics Collection Intervals in the vSphere Client

Statistic collection intervals determine the frequency at which statistic queries occur, the length of time statistical data is stored in the database, and the type of statistical data that is collected. You can view the collected statistics through the performance charts in the vSphere Client or through command-line monitoring utilities.

Required privilege: **Performance** > **ModifyIntervals**

> **Note:**
> Not all interval attributes are configurable.

1. In the vSphere Client, navigate to the vCenter instance.
2. Select the **Configure** tab.
3. Under **Settings**, select **General**.
4. Click **Edit**.
5. To enable or disable a statistics interval, check the box for that interval.
6. To change a statistics interval attribute value, select a value from the drop-down menu.
   a) In **Interval Duration**, select the time interval in which statistics data is collected.
   b) In **Save For**, select for how long the archived statistics are kept in the database.
   c) In **Statistics Level**, select a new level for collecting statistics.

      The lower the level is, the fewer number of statistic counters are used. Level 4 uses all statistics counters. Use it only for debugging purposes.

      The statistics level must be less than or equal to the statistics level that is set for the preceding statistics interval. This requirement is a vCenter dependency.
7. Optional: In Database Size, estimate the effect of the statistics settings on the database.
   a) Enter the number of **Physical Hosts**.
   b) Enter the number of **Virtual Machines**.

      The estimated space required and number of database rows required are calculated and displayed.

c) If necessary, make changes to your statistics collection settings.

8. Click **Save**.

Relationships Between the Default Settings for Statistics Intervals

- Samples that are collected every 5 minutes are stored for 1 day.
- Samples that are collected every 30 minutes are stored for 1 week.
- Samples that are collected every 2 hours are stored for 1 month.
- Samples that are collected on 1 day are stored for 1 year.

For all statistics intervals, the default level is 1. It uses the Cluster Services, CPU, Disk, Memory, Network, System, and Virtual Machine Operations counters.

Configure Runtime Settings for vCenter

You can change the vCenter ID, managed address, and name. You might need to make changes if you run multiple vCenter systems in the same environment.

Required privilege: **Global** > **Settings**

1. In the vSphere Client, navigate to the vCenter instance.
2. Select the **Configure** tab.
3. Under **Settings**, select **General**.
4. Click **Edit**.
5. In the Edit vCenter Settings dialog box, select **Runtime Settings**.
6. In **vCenter unique ID**, enter a unique ID.

   You can change this value to a number from 0 through 63 to identify each vCenter system running in a common environment. By default, an ID value is generated randomly.
7. In **vCenter managed address**, enter the vCenter system address.

   The address can be IPv4, IPv6, a fully qualified domain name, an IP address, or another address format.
8. In **vCenter name**, enter the name of the vCenter system.

   If you change the DNS name of the vCenter, you can use this text box to modify the vCenter name to match.
9. Click **Save**.

If you made changes to the vCenter system unique ID, you must restart the vCenter system for these changes to take effect.

Configure User Directory Settings

You can configure some of the ways vCenter interacts with the user directory server that is configured as an identity source.

Required privilege: **Global** > **Settings**

These settings apply to vCenter Single Sign-On identity sources.

1. In the vSphere Client, navigate to the vCenter instance.
2. Select the **Configure** tab.
3. Under **Settings**, select **General**.
4. Click **Edit**.
5. In the Edit vCenter general settings window, select **User directory**.
6. In **User directory timeout**, type the timeout interval in seconds for connecting to the directory server.
7. Enable the **Query Limit** box to set a query limit size.
8. In **Query Limit Size**, enter the number of users and groups for which you can associate permissions on the child inventory objects of the vCenter system.

   Note:
   You can associate permissions with users and groups from the Add Permissions dialog box that displays when you click **Add permissions** in **Manage** > **Permissions** for a vSphere inventory object.
9. Click **SAVE**.

Configure Mail Sender Settings

You must configure the email address of the sender account to use vCenter operations, such as sending email notifications as alarm actions. You can send email alerts and alarms using either anonymous or authentication mode.

Required privilege: **Global** > **Settings**

SMTP authentication is available for:

- vSphere 7.0 Update 1 and later versions only.
- Office 365 mailbox users only.
- SMTP mail sender should meet the basic requirements for SMTP Authentication as mentioned in Microsoft's document Requirement for SMTP AUTH client submission.

1. In the vSphere Client, navigate to the vCenter instance.
2. Select the **Configure** tab.
3. Under **Settings**, select **General**.
4. Click **Edit**.
5. Select **Mail** and enter the settings that vCenter uses to send email alerts.
6. In **Mail server** text box, enter the SMTP server information.

   The SMTP server is the DNS name or IP address of the SMTP gateway to use for sending email messages.

   - For sending mails anonymously, you can enter any SMTP server information as the mail server name.
   - For SMTP authentication, enter the mail server name as `smtp.office365.com`, unless you have some customized configuration.

     Note:
     Do not use IP address as mail server as IP address is not supported for SMTP authentication.
7. In **Mail sender** text box, enter the sender account information.

   The sender account is the email address of the sender.

   For SMTP authentication, you must enter a valid SMTP account name in the **Mail sender** text box.

   Note:
   You must enter the full email address, including the domain name.

   For example, *`mail_server@example.com`*

8. Click **SAVE**.
9. This step is applicable only for SMTP authentication.
   You must configure the SMTP user settings as below:
   1. Select the **Configure** tab.
   2. Select **Advanced Settings**.
   3. Click **EDIT SETTINGS** and enter the following values for the configuration parameters:

Name	Value
`mail.smtp.username`	Valid SMTP account name.
`mail.smtp.password`	Valid SMTP account password. **Note:** Currently, the account password is not masked and is visible. You must use a dedicated SMTP mail user until the masking is available in upcoming releases.
`mail.smtp.port`	587

   4. Click **SAVE**.

You can perform the following steps to test the mail settings:

1. Create an alarm that is triggered by a user action.
   For example, the user action can be powering off a virtual machine.
2. Verify that you receive an email, when the alarm is triggered.

Configure SNMP Settings

You can configure up to four receivers to receive SNMP traps from vCenter. For each receiver, specify a host name, port, and community.

Required privilege: **Global** > **Settings**

1. In the vSphere Client, navigate to the vCenter instance.
2. Select the **Configure** tab.
3. Under **Settings**, select **General**.
4. Click **Edit**.
5. Select **SNMP receivers**.
6. Select the **Enable receiver 1** box.
7. In **Primary Receiver URL**, enter the host name or IP address of the SNMP receiver.
8. In **Receiver port**, enter the port number of the receiver.
   The port number must be a value between 1 and 65535.

9. In **Community string**, enter the community identifier.
10. To send alarms to multiple receivers, select the additional **Enable receiver** boxes and enter the host name, port number, and community identifier for those receivers.
11. Click **Save**.

View Port Settings

You can view the ports used by the Web service to communicate with other applications. You cannot configure these port settings.

The Web service is installed as part of the vCenter installation. The Web service is a required component for third-party applications that use the VMware SDK application programming interface (API). For information about installing the Web service, see the Introduction to vSphere Deployment and Setupin the *vCenter Deployment and Setup* documentation.

1. In the vSphere Client, navigate to the vCenter instance.
2. Select the **Configure** tab.
3. Under **Settings**, select **General**.
4. Click **Edit**.
5. Select **Ports**.
   The ports used by the Web service are displayed.
6. Click **Save**.

Configure the Timeout Settings for the vSphere Client

By default, the vSphere Client sessions close after 120 minutes of inactivity. You can adjust this timeout setting within the vSphere Client.

Required privilege: **Global** > **Settings**

1. In the vSphere Client Home menu, select **Administration**.
2. Under **Deployment**, click **Client Configuration**.
3. On the **Client Configuration** page, click **Edit**.

   The **Edit client configuration** dialog opens.
4. Enter a new value in minutes in the **Session timeout** text field.
5. Click **Save**.
6. Re-login the vSphere Client for the changes to take effect.

Configure Logging Options

You can configure the amount of detail that vCenter collects in log files.

Required privilege: **Global** > **Settings**

1. In the vSphere Client, navigate to the vCenter instance.
2. Select the **Configure** tab.
3. Under **Settings**, select **General**.
4. Click **Edit**.
5. Select **Logging settings**.
6. Select the logging options.

Option	Description
None	Turns off logging

Option	Description
Error	Displays only error log entries
Warning	Displays warning and error log entries
Info	Displays information, error, and warning log entries
Verbose	Displays information, error, warning, and verbose log entries
Trivia	Displays information, error, warning, verbose, and trivia log entries

7. Click **SAVE**.

Changes to the logging settings take effect immediately. You do not need to restart the vCenter system.

Configure Advanced Settings

In **Advanced Settings**, you can modify the vCenter configuration file, `vpxd.cfg`.

Required privilege: **Global** > **Settings**

You can use **Advanced Settings** to add entries to the `vpxd.cfg` file, but not to edit or delete them. Broadcom recommends that you change these settings only when instructed to do so by Broadcom Support or when you are following specific instructions in the documentation.

1. In the vSphere Client, navigate to the vCenter instance.
2. Select the **Configure** tab.
3. Select **Advanced Settings**.
4. Click **Edit Settings**.
5. In the **Name** field, type a name for the setting. Names must start with 'config.' For example: `config.log`.
6. In the **Value** field, type the value for the specified setting.
7. Click **Add**.
8. Click **Save**.

Newly added advanced settings have `config.` appended to the setting keys in the `vpxd.cfg` file. For example:

```
config.example.setting = exampleValue
```

Many advanced settings changes require you to restart the vCenter system. Consult VMware technical support to determine if your changes require a restart.

Send a Message to Other Logged In Users

Administrators can send messages to users who are currently logged in to a vCenter system. The message might announce maintenance or ask users to log out temporarily.

1. In the vSphere Client, navigate to the vCenter instance.
2. Click **Configure**.
3. Select **Settings** > **Message of the Day** and click **Edit**.
4. Enter a message and click **OK**.

The message appears at the top of the vSphere Client in each active user session.

Add a User to the SystemConfiguration.BashShellAdministrators Group

To enable access to the appliance Bash shell by using the vSphere Client, the user you use to log in must be a member of the SystemConfiguration.BashShellAdministrators group. By default, this group is empty and you must add a user to the group manually.

Verify that the user you use to log in to the vCenter instance is a member of the SystemConfiguration.Administrators group in the vCenter Single Sign-On domain.

1. Use the vSphere Client to log in as administrator@*your_domain_name* to the vCenter instance.
   The address is of the type http://*appliance-IP-address-or-FQDN*/ui.
2. From the vSphere Client menu, select **Administration**.
3. Select **Single Sign On** > **Users and Groups**.
4. Click on the **Groups** tab, select **SystemConfiguration.BashShellAdministrators** from the options available in the Group Name column.
5. Click **EDIT**.
6. In the **Edit Group** window, to add members, select the domain from the dropdown menu and then search for the required users.
7. Click **SAVE**.

Reboot a Node

In the vSphere Client, you can reboot a node in vCenter.

Verify that the user you use to log in to the vCenter instance is a member of the SystemConfiguration.Administrators group in the vCenter Single Sign-On domain.

1. Use the vSphere Client to log in as administrator@*your_domain_name* to the vCenter instance.
2. On the vSphere Client main page, click **Administration** > **Deployment** > **System Configuration**.
3. Under System Configuration, select a node from the list.
   You can view the health status of a node. See View the Health Status of Nodes.
4. Click **REBOOT NODE**.

Export a Support Bundle

You can export a support bundle containing the log files for a specific product included in vCenter.

Verify that the user who logs in to the vCenter instance is a member of the `SystemConfiguration.Administrators` group in vCenter Single Sign-On.

1. Use the vSphere Client to log in as administrator@*your_domain_name* to the vCenter instance.
   The address is of the type http://*appliance-IP-address-or-FQDN*/ui.
2. On the vSphere Client home page, click **Administration** > **Deployment** > **System Configuration**.
3. Select a node from the list and click **Export Support Bundle**.
4. In the **Export Support Bundle** window, expand the trees to view the services running in the appliance and deselect the services for which you do not want to export log files.
   All the services are selected by default. If you want to export the support bundle and send it to Broadcom Support, leave all check boxes selected. The services are separated in two categories: a Cloud infrastructure category, which contains the services of specific products in the appliance, and a Virtual appliance category, which contains the services specific for the appliance and the vCenter product.
5. Click **Export Support Bundle** and save the bundle on your local machine.

You saved the support bundle to your machine and can explore it.

Using the Appliance Shell to Configure vCenter

You can access all of the vCenter API commands and plug-ins that you can use for monitoring, troubleshooting, and configuring the appliance by using the appliance shell.

You can run all commands in the appliance shell with or without the `pi` keyword.

Access the Appliance Shell

To access the plug-ins included in the appliance shell and to be able to see and use the API commands, first access the appliance shell.

1. Access the appliance shell.
   - If you have direct access to the appliance console, press Alt+F1.
   - If you want to connect remotely, use SSH or another remote console connection to start a session to the appliance.
2. Enter a user name and password recognized by the appliance.

You are logged in to the appliance shell and can see the welcome message.

Enable and Access the Bash Shell from the Appliance Shell

If you log in to the appliance shell as a user who has a super administrator role, you can enable access to the Bash shell of the appliance for other users. The root user has access to the appliance Bash shell by default.

The appliance Bash shell is enabled by default for the root

1. Access the appliance shell and log in as a user who has a super administrator role.
   The default user with a super administrator role is root.
2. If you want to enable the Bash shell access for other users, run the following command.
   ```
   shell.set --enabled true
   ```
3. To access the Bash shell run `shell` or `pi shell`.

Keyboard Shortcuts for Editing Commands

You can use various keyboard shortcuts to enter and edit commands in the appliance Bash shell.

Table 66: Keyboard Shortcuts and Function

Keyboard Shortcut	Details
Tab	Completes the current command. If you enter a part of the command name and press the Tab key, the system completes the command name. To view the commands that match a set of characters that you enter, type a character and press the Tab key.
Enter (at the command line)	Runs the command that you entered.
Enter (at the **More** prompt)	Displays the next page of output.
Delete or Backspace	Deletes the character that is on the left of the cursor.
Left arrow or Ctrl+B	Moves the cursor one character to the left. When you enter a command that extends beyond a single line, you can press the Left Arrow or Ctrl-B keys to go back to the beginning of the command.
Right arrow or Ctrl+F	Moves the cursor one character to the right.
Esc, B	Moves the cursor one word back.
Esc, F	Moves the cursor one word forward.
Ctrl+A	Moves the cursor to the beginning of the command line.
Ctrl+E	Moves the cursor to the end of the command line.
Ctrl+D	Deletes the character selected by the cursor.
Ctrl+W	Deletes the word next to the cursor.
Ctrl+K	Deletes the line forward. When you press Ctrl+K, everything that you entered starting from the cursor location to the end of the command line is deleted.

Keyboard Shortcut	Details
Ctrl+U or Ctrl+X	Deletes the line backward. When you press Ctrl+U, everything from the beginning of the command line to the cursor location is deleted.
Ctrl+T	Changes the places of the character to the left of the cursor with the character selected by the cursor.
Ctrl+R or Ctrl+L	Displays the system prompt and command line.
Ctrl+V or Esc, Q	Inserts a code to indicate to the system that the following keystroke must be treated as a command entry, not as an editing key.
Up arrow, or Ctrl+P	Recalls commands in the history buffer, beginning with the most recent command.
Down arrow or Ctrl+N	Returns to more recent commands in the history buffer after you use the Up arrow or Ctrl+P to recall commands.
Ctrl+Y	Recalls the most recent entry in the delete buffer. The delete buffer contains the last 10 items you have cut or deleted.
Esc, Y	Recalls the next entry in the delete buffer. The delete buffer contains the last 10 items you have cut or deleted. Press Ctrl+Y first to recall the most recent entry, and then press Esc, Y up to nine times to recall the remaining entries in the buffer.
Esc, C	Capitalizes the character selected by the cursor.
Esc, U	Changes the casing for all characters in the word selected by the cursor, up to the next space, to uppercase.
Esc, L	Changes the capitalized letters in a word from the character selected by the cursor to the end of the word to lowercase.

Get Help on APIs and Utilities

You can access the vCenter plug-ins and API commands from the appliance shell. You can use the plug-ins and commands for monitoring, troubleshooting, and configuring the appliance.

You can use the Tab key to auto complete API commands, plug-in names, and API parameters. Plug-in parameters do not support auto completion.

1. Access the appliance shell and log in.
2. To get help about the plug-ins, run the `help pi list` or the `? pi list` command.
   You receive a list with all the plug-ins in the appliance.
3. To get help about the API commands, run the `help api list` or the `? api list` command.
   You receive a list with all the API commands in the appliance.
4. To get help about a particular API command, run the `help api` *`api_name`* or the `? api` *`api_name`* command. For example, to receive help about the `com.vmware.appliance.version1.timesync.set` command, run `help api timesync.set` or `? api timesync.set`.

Plug-Ins in vCenter Shell

The plug-ins in vCenter provide you with access to various administrative tools. The plug-ins reside in the CLI itself. The plug-ins are standalone Linux or VMware utilities, which do not depend on any VMware service.

Table 67: Plug-Ins Available in the vCenter

Plug-In	Description
`com.vmware.clear`	A plug-in that you can use to clear the terminal screen.
`com.vmware.cmsso-util`	A plug-in that you use for orchestrating changes to PNID, Machine Certificate, unregistering a node from Component Manager, vCenter Single Sign-On, and reconfiguring vCenter.

Plug-In	Description
com.vmware.dcli	vAPI based CLI client.
com.vmware.nslookup	A plug-in that you can use to query the Domain Name System (DNS) to obtain domain name or IP address mapping or for any other specific DNS record.
com.vmware.pgrep	A plug-in that you can use to search for all named processes.
com.vmware.pgtop	A plug-in that you can use to monitor the PostgreSQL database.
com.vmware.ping	A plug-in that you can use to ping a remote host. Accepts the same arguments as bin/ping.
com.vmware.ping6	A plug-in that you can use to ping a remote host. Accepts the same arguments as bin/ping6.
com.vmware.portaccess	A plug-in that you can use to troubleshoot the port access of a host.
com.vmware.ps	A plug-in that you can use to see statistics on running processes.
com.vmware.rvc	Ruby vSphere Console
com.vmware.service-control	A plug-in that you can use to manage VMware services.
com.vmware.shell	A plug-in that allows access to the appliance Bash shell.
com.vmware.showlog	A plug-in that you can use to browse the log files.
com.vmware.shutdown	A plug-in that you can use to restart or power off the appliance.
com.vmware.software-packages	A plug-in that you can use to update the software packages in the appliance.
com.vmware.support-bundle	A plug-in that you can use to create a bundle on the local file system and export it to a remote Linux system. If you use the plug-in with the `stream` command, the support bundle is not created on the local file system, but is directly exported to the remote Linux system.
com.vmware.top	A plug-in that displays process information. Accepts the same arguments as /usr/bin/top/.
com.vmware.tracepath	A plug-in that traces the path to a network host. Accepts the same arguments as /sbin/tracepath.
com.vmware.tracepath6	A plug-in that traces the path to a network host. Accepts the same arguments as /sbin/tracepath6.
com.vmware.updatemgr-util	A plug-in that you can use to configure VMware Update Manager.
com.vmware.vcenter-restore	A plug-in that you can use to restore vCenter.
com.vmware.vimtop	A plug-in that you can use to view a list of vSphere services and their resource use.

Browse Log Files Using showlog Plug-In

You can browse the log files in vCenter to examine them for errors.

1. Access the appliance shell and log in.
2. Type the `showlog` command, add a space, and press the Tab key to view all the contents of the `/var/log` folder.
3. Run the command for viewing the firstboot log files.

```
showlog /var/log/firstboot/cloudvm.log
```

API Commands in Appliance Shell

The API commands in vCenter let you perform various administrative tasks. The API commands are provided by appliance management service. You can edit time synchronization settings, monitor processes and services, set up the SNMP settings, and so on.

Table 68: API Commands Available in vCenter

API Command	Description
com.vmware.appliance.health.applmgmt.get	Get the health of the applmgmt service.
com.vmware.appliance.health.databasestorage.get	Get the health of the database storage.
com.vmware.appliance.health.load.get	Get the CPU load health.
com.vmware.appliance.health.mem.get	Get the memory health.
com.vmware.appliance.health.softwarepackages.get	Get the health of the system update.
com.vmware.appliance.health.storage.get	Get the overall storage health.
com.vmware.appliance.health.swap.get	Get the swap health.
com.vmware.appliance.health.system.get	Get the system health.
com.vmware.appliance.health.system.lastcheck	Get the time of the last check of the health status.
com.vmware.appliance.monitoring.list	Get a list of monitored items.
com.vmware.appliance.monitoring.get	Get monitored item information.
com.vmware.appliance.monitoring.query	Query a range of values for the monitored items.
com.vmware.appliance.recovery.backup.job.cancel	Cancel a backup job by id.
com.vmware.appliance.recovery.backup.job.create	Start a backup job.
com.vmware.appliance.recovery.backup.job.get	Get a status of the backup job by id.
com.vmware.appliance.recovery.backup.job.list	Get a list of backup jobs.
com.vmware.appliance.recovery.backup.parts.list	Get a list of the vCenter components that can be included in a backup job.
com.vmware.appliance.recovery.backup.parts.get	Get detailed info for a backup part.
com.vmware.appliance.recovery.backup.validate	Validate parameters for a backup job without starting the job.
com.vmware.appliance.recovery.restore.job.cancel	Cancel a restore job.
com.vmware.appliance.recovery.restore.job.create	Start a restore job.
com.vmware.appliance.recovery.restore.job.get	Get status of the restore job.
com.vmware.appliance.recovery.restore.validate	Validate restore parameters of a restore job without starting the job.
com.vmware.appliance.system.uptime.get	Gets the system uptime.
com.vmware.appliance.version1.access.consolecli.get	Get information about the state of the console-based controlled CLI (TTY1).
com.vmware.appliance.version1.access.consolecli.set	Set enabled state of console-based controlled CLI (TTY1).
com.vmware.appliance.version1.access.dcui.get	Get information about the state of the Direct Console User Interface (DCUI TTY2).
com.vmware.appliance.version1.access.dcui.set	Set enabled state of the Direct Console User Interface (DCUI TTY2).
com.vmware.appliance.version1.access.shell.get	Get information about the state of Bash shell, that is, access to Bash shell from within the controlled CLI.

API Command	Description
com.vmware.appliance.version1.access.shell.set	Set enabled state of Bash shell, that is, access to Bash shell from within the controlled CLI.
com.vmware.appliance.version1.access.ssh.get	Get enabled state of the SSH-based controlled CLI.
com.vmware.appliance.version1.access.ssh.set	Set enabled state of the SSH-based controlled CLI.
com.vmware.appliance.version1.localaccounts.user.add	Create a new local user account.
com.vmware.appliance.version1.localaccounts.user.delete	Delete a local user account.
com.vmware.appliance.version1.localaccounts.user.get	Get the local user account information.
com.vmware.appliance.version1.localaccounts.user.list	List local user accounts.
com.vmware.appliance.version1.localaccounts.user.password.update	Update the password of a logged in user or of the user that you specify in the username parameter.
com.vmware.appliance.version1.localaccounts.user.set	Update local user account properties, such as role, full name, enabled status, and password.
com.vmware.appliance.version1.monitoring.snmp.disable	Stop an enabled SNMP agent.
com.vmware.appliance.version1.monitoring.snmp.enable	Start a disabled SNMP agent.
com.vmware.appliance.version1.monitoring.snmp.get	Return an SNMP agent configuration.
com.vmware.appliance.version1.monitoring.snmp.hash	Generate localized keys for secure SNMPv3 communications.
com.vmware.appliance.version1.monitoring.snmp.limits	Get SNMP limits information.
com.vmware.appliance.version1.monitoring.snmp.reset	Restore settings to factory defaults.
com.vmware.appliance.version1.monitoring.snmp.set	Set SNMP configuration.
com.vmware.appliance.version1.monitoring.snmp.stats	Generate diagnostics report for SNMP agent.
com.vmware.appliance.version1.networking.dns.domains.add	Add domains to DNS search domains.
com.vmware.appliance.version1.networking.dns.domains.list	Get a list of DNS search domains.
com.vmware.appliance.version1.networking.dns.domains.set	Set DNS search domains.
com.vmware.appliance.version1.networking.dns.hostname.get	Get the Fully Qualified Domain Name.
com.vmware.appliance.version1.networking.dns.hostname.set	Set the Fully Qualified Domain Name.
com.vmware.appliance.version1.networking.dns.servers.add	Add a DNS server. This method fails if you use DHCP.
com.vmware.appliance.version1.networking.dns.servers.get	Get DNS server configuration.
com.vmware.appliance.version1.networking.dns.servers.set	Set the DNS server configuration. If the host is configured to acquire DNS servers and host name by using DHCP, a DHCP refresh is forced.
com.vmware.appliance.version1.networking.firewall.addr.inbound.add	Add a firewall rule to allow or deny access from an incoming IP address.
com.vmware.appliance.version1.networking.firewall.addr.inbound.delete	Delete a specific rule at a given position or delete all rules.
com.vmware.appliance.version1.networking.firewall.addr.inbound.list	Get an ordered list of inbound IP addresses that are allowed or denied by a firewall rule.

API Command	Description
com.vmware.appliance.version1.networking.interfaces.get	Get information about a particular network interface.
com.vmware.appliance.version1.networking.interfaces.list	Get a list of available network interfaces, including interfaces that are not yet configured.
com.vmware.appliance.version1.networking.ipv4.get	Get IPv4 network configuration for interfaces.
com.vmware.appliance.version1.networking.ipv4.list	Get IPv4 network configuration for all configured interfaces.
com.vmware.appliance.version1.networking.ipv4.renew	Renew IPv4 network configuration on interfaces. If the interface is configured to use DHCP for IP address assignment, the lease of the interface is renewed.
com.vmware.appliance.version1.networking.ipv4.set	Set IPv4 network configuration for an interface.
com.vmware.appliance.version1.networking.ipv6.get	Get IPv6 network configuration for interfaces.
com.vmware.appliance.version1.networking.ipv6.list	Get IPv6 network configuration for all configured interfaces.
com.vmware.appliance.version1.networking.ipv6.set	Set IPv6 network configuration for an interface.
com.vmware.appliance.version1.networking.routes.add	Add static routing rules. A destination/prefix of the type 0.0.0.0/0 (for IPv4) or ::/0 (for IPv6) refers to the default gateway.
com.vmware.appliance.version1.networking.routes.delete	Delete static routing rules.
com.vmware.appliance.version1.networking.routes.list	Get routing table. A destination/prefix of the type 0.0.0.0/0 (for IPv4) or ::/0 (for IPv6) refers to the default gateway.
com.vmware.appliance.ntp.get	Get NTP configuration settings. If you run the `tymesync.get` command, you can retrieve the current time synchronization method (by using NTP or VMware Tools). The `ntp.get` command always returns the NTP server information, even when the time synchronization method is not set to NTP. If time synchronization method is not set by using NTP, the NTP status is displayed as down.
com.vmware.appliance.version1.ntp.server.add	Add NTP servers. This command adds NTP servers to the configuration. If the time synchronization is NTP-based, then NTP daemon is restarted to reload the new NTP servers. Otherwise, this command just adds servers to the NTP configuration.

API Command	Description
com.vmware.appliance.version1.ntp.server.delete	Delete NTP servers. This command deletes NTP servers from the configuration. If the time synchronization mode is NTP-based, the NTP daemon is restarted to reload the new NTP configuration. Otherwise, this command just deletes servers from the NTP configuration.
com.vmware.appliance.version1.ntp.server.set	Set NTP servers. This command deletes old NTP servers from the configuration and sets the input NTP servers in the configuration. If the time synchronization is set by using NTP, the NTP daemon is restarted to reload the new NTP configuration. Otherwise, this command just replaces the servers in NTP configuration with the NTP servers that you provide as input.
com.vmware.appliance.version1.resources.cpu.stats.get	Get CPU statistics.
com.vmware.appliance.version1.resources.load.health.get	Get load health.
com.vmware.appliance.version1.resources.load.stats.get	Get load averages (over 1, 5, and 15-minute intervals).
com.vmware.appliance.version1.resources.mem.health.get	Get memory health.
com.vmware.appliance.version1.resources.mem.stats.get	Get memory statistics.
com.vmware.appliance.version1.resources.net.stats.get	Get network statistics.
com.vmware.appliance.version1.resources.net.stats.list	Get network statistics for all interfaces that are up and running.
com.vmware.appliance.version1.resources.processes.stats.list	Get statistics on all processes.
com.vmware.appliance.version1.resources.softwarepackages.health.get	Get the health of the update component.
com.vmware.appliance.version1.resources.storage.health.get	Get storage health statistics.
com.vmware.appliance.version1.resources.storage.stats.list	Get storage statistics for each logical disk.
com.vmware.appliance.version1.resources.swap.health.get	Get swap health.
com.vmware.appliance.version1.resources.swap.stats.get	Get swap statistics.
com.vmware.appliance.version1.resources.system.health.get	Get the overall health of the system.
com.vmware.appliance.version1.resources.system.stats.get	Get the system status.
com.vmware.appliance.version1.services.list	Get the list of all known services.
com.vmware.appliance.version1.services.restart	Restart a service.
com.vmware.appliance.version1.services.status.get	Get the status of a service.
com.vmware.appliance.version1.services.stop	Stop a service.
com.vmware.appliance.version1.system.storage.list	Gets disk to partition mapping.
com.vmware.appliance.version1.system.storage.resize	Resizes all partitions to 100 percent of disk size.
com.vmware.appliance.version1.system.time.get	Gets system time.
com.vmware.appliance.version1.system.update.get	Get the URL-based patching configuration.
com.vmware.appliance.version1.system.update.set	Set the URL-based patching configuration.

API Command	Description
com.vmware.appliance.version1.system.version.get	Get the version of the appliance.
com.vmware.appliance.version1.timesync.get	Get the time synchronization configuration.
com.vmware.appliance.version1.timesync.set	Set the time synchronization configuration.

Configuring SNMP for vCenter

vCenter includes an SNMP agent that can send trap notifications and receive GET, GETBULK, and GETNEXT requests.

You can use the appliance shell API commands to enable and configure the vCenter SNMP agent. You configure the agent differently depending on whether you want to use SNMP v1/v2c or SNMP v3.

SNMP v3 informs are not supported. vCenter supports only notifications such as v1 and v2c traps, and v3 traps with all security levels.

Configure the SNMP Agent for Polling

If you configure the vCenter SNMP agent for polling, it can listen for and respond to requests from SNMP management client systems, such as GET, GETNEXT, and GETBULK requests.

By default, the embedded SNMP agent listens on UDP port 161 for polling requests from management systems. You can use the snmp.set --port command to configure an alternative port. To avoid conflicts between the port for the SNMP agent and the ports of other services, use a UDP port that is not defined in /etc/services.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.
   The default user with super administrator role is root.
2. Run the snmp.set --port command to configure the port.
   For example, run the following command:
   ```
   snmp.set --port port
   ```
   Here *port* is the port for the SNMP agent to use for listening for polling requests.

   Important:
   The port you specify must not be already in use by other services. Use IP addresses from the dynamic range, port 49152 and up.
3. Optional: If the SNMP agent is not enabled, enable it by running the snmp.enable command.

Configure vCenter for SNMP v1 and v2c

When you configure the vCenter SNMP agent for SNMP v1 and v2c, the agent supports sending notifications and receiving GET requests.

In SNMP v1 and v2c, community strings are namespaces that contain one or more managed objects. Namespaces can act as a form for authentication, but this does not secure the communication. To secure the communication, use SNMP v3.

Configure SNMP Communities

To enable the vCenter SNMP agent to send and receive SNMP v1 and v2c messages, you must configure at least one community for the agent.

An SNMP community defines a group of devices and management systems. Only devices and management systems that are members of the same community can exchange SNMP messages. A device or management system can be a member of multiple communities.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.
   The default user with super administrator role is root.
2. Run the snmp.set --communities command to configure an SNMP community.
   For example, to configure public, east, and west network operation center communities, run the following command:

```
snmp.set --communities public,eastnoc,westnoc
```

Each time you specify a community with this command, the settings you specify overwrite the previous configuration.

To specify multiple communities, separate the community names with a comma.

Configure SNMP Agent to Send v1 or v2c Notifications

You can use the vCenter SNMP agent to send virtual machine and environmental notifications to management systems.

To send SNMP v1 and v2c notifications with the SNMP agent, you must configure the target, that is the receiver, unicast address, community, and an optional port. If you do not specify a port, the SNMP agent sends notifications to UDP port 162 on the target management system by default.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.

   The default user with super administrator role is root.

2. Run the `snmp.set --targets` command:

   ```
   snmp.set --targets target_address@port/community
   ```

   Here *`target_address`*, *`port`*, and *`community`* are the address of the target system, the port number to send the notifications to, and the community name, respectively. The port value is optional. If you do not specify a port, the default port,161, is used.

   Each time you specify a target with this command, the settings you specify overwrite all previously specified settings. To specify multiple targets, separate them with a comma.

   For example, run the following command for configuring the targets 192.0.2.1@678/targetcommunity and 2001:db8::1/anothercom:

   ```
   snmp.set --targets 192.0.2.1@678/targetcommunity,2001:db8::1/anothercom
   ```

3. Optional: If the SNMP agent is not enabled, enable it by running the `snmp.enable` command.
4. Optional: To send a test trap to verify that the agent is configured correctly, run the `snmp.test` command.

   The agent sends a `warmStart` trap to the configured target.

Configure vCenter for SNMP v3

When you configure the SNMP agent for SNMP v3, the agent supports sending traps. SNMP v3 also provides stronger security than v1 or v2c, including cryptographic authentication and encryption.

SNMP v3 informs are not supported. vCenter supports only notifications such as v1/v2c traps and v3 traps with all security levels.

Configure SNMP Engine ID

Every SNMP v3 agent has an engine ID, which serves as a unique identifier for the agent. The engine ID is used with a hashing function to generate localized keys for authentication and encryption of SNMP v3 messages.

If you do not specify an engine ID before you enable the SNMP agent, when you enable the standalone SNMP agent, an engine ID is generated.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.

   The default user with super administrator role is root.

2. Run the `snmp.set --engineid` command to configure the target.
   For example, run the following command:

   ```
   snmp.set --engineid 80001adc040102030405060708091011
   ```

   where, the value can be broken into hexidecimal digits,

   ```
   80:00:1a:dc:04:24:17:e2:02:b8:61:3f:54:00:00:00:00
   ```

   and decoded as:

   80: -- RFC 3411 encoding applies as high bit '10000000' 0x80 and lower 7 bits 0 are part of enterprise id.

   00:1a:dc -- rest of enterprise id, the value parsed by vmware is, 1a:dc hexidecimal (6876 in decimal).

04: -- type of engineid as per RFC 3411, page 42. Using here '4' to say remaining octets can be tranlated to text.

0102030405060708091011 -- operator specified text encoded in hexidecmal characters.

Configure SNMP Authentication and Privacy Protocols

SNMP v3 optionally supports authentication and privacy protocols.

Authentication is used to ensure the identity of users. Privacy allows for encryption of SNMP v3 messages to ensure confidentiality of data. The privacy protocols provide a higher level of security than is available in SNMP v1 and v2c, which use community strings for security.

Both authentication and privacy are optional. However, you must enable authentication if you plan to enable privacy.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.

   The default user with super administrator role is root.

2. Optional: Run the `snmp.set --authentication` command to configure authentication.
   For example, run the following command:

   ```
   snmp.set --authentication protocol
   ```

   Here, *`protocol`* must be either `none`, for no authentication,`SHA1`, or `MD5`.

3. Optional: Run the `snmp.set --privacy` command to configure privacy protocol.
   For example, run the following command:

   ```
   snmp.set --privacy protocol
   ```

   Here, *`protocol`* must be either `none`, for no privacy, or `AES128`.

Configure SNMP Users

You can configure up to five users who can access SNMP v3 information. User names must be no more than 32 characters long.

- Verify that you have configured the authentication and privacy protocols before configuring users.
- Verify that you know the authentication and privacy passwords for each user that you plan to configure. Passwords must be at least eight characters long. Store these passwords in files on the host system.

While configuring a user, you generate authentication and privacy hash values based on the user's authentication and privacy passwords and on the SNMP agent's engine ID. After configuring users, if you change the engine ID, the authentication protocol, or the privacy protocol, the users are no longer valid and must be reconfigured.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.

   The default user with super administrator role is root.

2. If you are using authentication or privacy, get the authentication and privacy hash values for the user by the running `snmp.hash --auth_hash --priv_hash` command.
   For example, run the following command:

   ```
   snmp.hash  --auth_hashsecret1--priv_hashsecret2
   ```

   Here, *`secret1`* is the path to the file containing the user's authentication password and *`secret2`* is the path to the file containing the user's privacy password. Alternatively, you can specify the flag `--raw_secret` and set the boolean parameter to *`true`*.

   The authentication and privacy hash values are displayed.

3. Configure the user by running `snmp.set --user`.
   For example, run the following command:

   ```
   snmp.set --useruserid/authhash/privhash/security
   ```

   The parameters in the command are as follows.

Parameter	Description
`userid`	Replace with the user ID.
`authhash`	Replace with the authentication hash value.

Parameter	Description
privhash	Replace with the privacy hash value.
security	Replace with the level of security enabled for that user, which can be `auth`, for authentication only, `priv`, for authentication and privacy, or `none`, for no authentication or privacy.

Configure SNMP v3 Targets

Configure SNMP v3 targets to allow the SNMP agent to send SNMP v3 traps.

You can configure a maximum of three SNMP v3 targets, in addition to a maximum of three SNMP v1 or v2c targets.

To configure a target, you must specify a host name or IP address of the system that receives the traps, a user name, a security level, and whether to send traps. The security level can be either `none`, for no security, `auth`, for authentication only, or `priv`, for authentication and privacy.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.
   The default user with super administrator role is root.
2. Run the `snmp.set --v3targets` command to set up the SNMP v3 target.
   For example, run the following command:
   ```
   snmp.set --v3targetshostname@port/userid/secLevel/trap
   ```
   The parameters in the command are as follows.

Parameter	Description
hostname	Replace with the host name or IP address of the management system that receives the traps.
port	Replace with the port on the management system that receives the traps. If you do not specify a port, the default port, 161, is used.
userid	Replace with the user name.
secLevel	Replace with either `none`, `auth`, or `priv` to indicate the level of authentication and privacy you have configured. Use `auth` if you have configured authentication only, `priv` if you have configured both authentication and privacy, and `none` if you have configured neither.

3. Optional: If the SNMP agent is not enabled, enable it by running the `snmp.enable` command.
4. Optional: To send a test trap to verify that the agent is configured correctly, run the `snmp.test` command.
   The agent sends a `warmStart` trap to the configured target.

Configure SNMP Agent to Filter Notifications

You can configure the vCenter SNMP agent to filter out notifications if you do not want your SNMP management software to receive those notifications.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.
   The default user with super administrator role is root.
2. Run the `snmp.set --notraps` command to filter traps.
   - To filter specific traps, run the following command:
     ```
     snmp.set  --notraps oid_list
     ```
     Here, *oid_list* is a list of object IDs for the traps to filter, separated by commas. This list replaces any object IDs that were previously specified using this command.
   - To clear all trap filters, run the following command:
     ```
     snmp.set  --notraps reset
     ```
3. Optional: If the SNMP agent is not enabled, enable it by running the `snmp.enable` command.

The traps identified by the specified object IDs are filtered out of the output of the SNMP agent, and are not sent to SNMP management software.

Configure SNMP Management Client Software

After you have configured vCenter to send traps, you must configure your management client software to receive and interpret those traps.

Download the VMware MIB files. See Broadcom knowledge base article 313538.

To configure your management client software, specify the communities for the managed device, configure the port settings, and load the VMware MIB files. See the documentation for your management system for specific instructions for these steps.

1. In your management software, specify the vCenter instance as an SNMP-based managed device.
2. If you are using SNMP v1 or v2c, set up appropriate community names in the management software.
   These names must correspond to the communities set for the SNMP agent on vCenter.
3. If you are using SNMP v3, configure users and authentication and privacy protocols to match the protocols configured on vCenter.
4. If you configured the SNMP agent to send traps to a port on the management system other than the default UDP port 162, configure the management client software to listen on the port you configured.
5. Load the VMware MIBs into the management software to view the symbolic names for the vCenter variables.
   To prevent lookup errors, load these MIB files in the following order before loading other MIB files:
   1. `VMWARE-ROOT-MIB.mib`
   2. `VMWARE-TC-MIB.mib`
   3. `VMWARE-PRODUCTS-MIB.mib`

The management software can now receive and interpret traps from vCenter.

Reset SNMP Settings to Factory Defaults

You can reset SNMP settings to factory defaults. You can also reset the value of a specific argument to the factory default.

You can reset a specific argument, such as the communities or targets. You can also reset the SNMP configuration to the factory defaults.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.
   The default user with super administrator role is root.
2. To reset specific arguments, run the command `snmp.set --arguments reset`.
   For example, to reset the communities that you configured, run the following command:
   ```
   snmp.set --communities reset
   ```
3. To reset the whole SNMP configuration to the factory defaults, run the command `snmp.reset`.

Configuring Time Synchronization Settings in vCenter

You can change the time synchronization settings in vCenter after deployment.

When you deploy vCenter, you can choose the time synchronization method to be either by using an NTP server or by using VMware Tools. In case the time settings in your vSphere network change, you can edit the vCenter and configure the time synchronization settings by using the commands in the appliance shell.

When you enable periodic time synchronization, VMware Tools sets the time of the guest operating system to be the same as the time of the ESXhost.

After time synchronization occurs, VMware Tools checks once every minute to determine whether the clocks on the guest operating system and the host still match. If not, the clock on the guest operating system is synchronized to match the clock on the host.

Native time synchronization software, such as Network Time Protocol (NTP), is typically more accurate than VMware Tools periodic time synchronization and is therefore preferred. You can use only one form of periodic time synchronization

in vCenter. If you decide to use native time synchronization software, vCenter VMware Tools periodic time synchronization is deactivated.

Use VMware Tools Time Synchronization

You can set up vCenter to use VMware Tools time synchronization.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.
   The default user with super administrator role is root.
2. Run the command to enable VMware Tools time synchronization.
   ```
   timesync.set --mode host
   ```
3. Optional: Run the command to verify that you successfully applied the VMware Tools time synchronization.
   ```
   timesync.get
   ```
   The command returns that the time synchronization is in host mode.

The time of the appliance is synchronized with the time of the ESX host.

Add or Replace NTP Servers in the vCenter Configuration

To set up the vCenter to use NTP-based time synchronization, you must add the NTP servers to the vCenter configuration.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.
   The default user with super administrator role is root.
2. Add NTP servers to the vCenter configuration by running the following `ntp.set` command.
   ```
   ntp.set --servers IP-addresses-or-host-names
   ```
   In this command, *`IP-addresses-or-host-names`* is a comma-separated list of IP addresses or host names of the NTP servers.
   This command removes the current NTP servers (if any) and adds the new NTP servers to the configuration. If the time synchronization is based on an NTP server, then the NTP daemon is restarted to reload the new NTP servers. Otherwise, this command replaces the current NTP servers in the NTP configuration with the new NTP servers you specify.
3. Optional: To verify that you successfully applied the new NTP configuration settings, run the following command.
   ```
   ntp.get
   ```
   The command returns a space-separated list of the servers configured for NTP synchronization. If the NTP synchronization is activated, the command returns that the NTP configuration is in Up status. If the NTP synchronization is deactivated, the command returns that the NTP configuration is in Down status.
4. Optional: To verify if the NTP server is reachable, run the following command.
   ```
   ntp.test --servers IP-addresses-or-host-names
   ```
   The command returns the status of the NTP servers.

If the NTP synchronization is deactivated, you can configure the time synchronization settings in the vCenter to be based on an NTP server. See Synchronize the Time in vCenter with an NTP Server.

Synchronize the Time in vCenter with an NTP Server

You can configure the time synchronization settings in the vCenter to be based on an NTP server.

Set up one or more Network Time Protocol (NTP) servers in the vCenter configuration. See Add or Replace NTP Servers in the vCenter Configuration.

1. Access the appliance shell and log in as a user who has the administrator or super administrator role.
   The default user with super administrator role is root.

2. Run the command to enable NTP-based time synchronization.
   ```
   timesync.set --mode NTP
   ```
3. Optional: Run the command to verify that you successfully applied the NTP synchronization.
   ```
   timesync.get
   ```
   The command returns that the time synchronization is in NTP mode.

Managing Appliance Local User Accounts in vCenter

If you log in to the appliance shell as a super administrator, you can manage the local user accounts in vCenter by running commands in the appliance shell. The default user with a super administrator role is root.

User Roles in vCenter

There are three main user roles in vCenter.

The local users of vCenter have the rights to perform various tasks. Three user roles are available in vCenter:

Operator	Local users with the operator user role can read vCenter configuration.
Administrator	Local users with the administrator user role can configure vCenter.
Super Administrator	Local users with the super administrator user role can configure vCenter, manage the local accounts, and use the Bash shell.

Get a List of the Appliance Local User Accounts in vCenter

You can see the list of the local user accounts so that you can decide which user account to manage from the appliance shell.

1. Access the appliance shell and log in as a user who has a super administrator role.
   The default user with a super administrator role is root.
2. Run the `localaccounts.user.list` command.
   You can see a list of the local users. The information about a user includes the user name, status, role, status of the password, full name, and email.

   Note:
   The list of local users includes only the local users who have their default shell as appliance shell.

Create an Appliance Local User Account in vCenter

You can create a new appliance local user account.

- To create or modify appliance local accounts using the appliance shell, you must log in as `root` or as a local account assigned the `superAdmin` role.

For information about the user roles, see User Roles in vCenter.

Note:

Appliance Local User Accounts and vCenter SSO Users

- Appliance local user accounts
  The `localaccounts.user` commands manage local Linux OS users on the vCenter appliance, such as `root` or other local CLI accounts. You can also manage these accounts through the vCenter Management Interface (VAMI) at `https://<vcenter-ip>:5480`.
- vCenter SSO users (`vsphere.local`)
  Appliance shell `localaccounts` commands do not manage vCenter Single Sign-On users, such as `administrator@vsphere.local`. To create, modify, or reset passwords for SSO users, log in to the vSphere Client and navigate to **Administrator** > **Single Sign-On** > **Users and Groups**.

1. Access the appliance shell and log in as a user who has a super administrator role.
   The default user with a super administrator role is root.
2. Run the `localaccounts.user.add --role <role> --username <user_name> --password <password>` command.
   For example, to add the local user account `test` with the `operator` user role, run the following command:
   ```
   localaccounts.user.add --role operator --username test --password testPass
   ```
   The role can be `operator`, `admin`, or `superAdmin`.
   You can also set up a new local user account and specify an email and the full name of the user. For example, to add the local user account `test1` with the `operator` user role, full name `TestName` and the email address `test1@mymail.com`, run the following command:
   ```
   localaccounts.user.add --role operator --username test1 --password --fullname TestName --email
    test1@mymail.com
   ```
   You cannot use spaces in full names.
3. Enter and confirm the password of the new local user when prompted.

You created a new local user in the appliance.

Update Password of an Appliance Local User in vCenter

You can update the password of a local user in vCenter for security reasons.

1. Access the appliance shell and log in as a user who has a super administrator role.
   The default user with a super administrator role is root.
2. Run the `localaccounts.user.password.update --username user name --password` command.
   For example, to change the password of a user with user name test, run the following command:
   ```
   localaccounts.user.password.update --username test --password
   ```
3. Enter and confirm the new password when prompted.
   The password expiration period for local accounts is 90 days by default.

Update an Appliance Local User Account in vCenter

You can update an existing local user account in vCenter.

For information about the user roles, see User Roles in vCenter.

1. Access the appliance shell and log in as a user who has a super administrator role.
   The default user with a super administrator role is root.
2. Run the `localaccounts.user.set --username` command to update an existing local user.
   - To update the role of the local user, run the following command:
     ```
     localaccounts.user.set --username user name --role new role
     ```
     Here, *`user name`* is the name of the user that you want to edit and *`new role`* is the new role. The role can be `operator`, `admin`, or `superAdmin`.
   - To update the email of the local user, run the following command:
     ```
     localaccounts.user.set --username user name --email new email address
     ```
     Here, *`user name`* is the name of the user that you want to edit and *`new email address`* is the new email address.
   - To update the full name of the local user, run the following command:
     ```
     localaccounts.user.set --username user name --fullname new full name
     ```
     Here, *`user name`* is the name of the user that you want to edit and *`new full name`* is the new full name of the user.

- To update the status of the local user, run the following command:
  `localaccounts.user.set --username user name --status new status`
  Here, *user name* is the name of the user that you want to edit and *status* is the new status of the local user. The status can be either `disabled` or `enabled`.

Delete an Appliance Local User Account in vCenter

You can delete a local user account in vCenter.

1. Access the appliance shell and log in as a user who has a super administrator role.
   The default user with a super administrator role is root.
2. Run the `localaccounts.user.delete --username` command.
   For example, to delete the user with user name test, run the following command:
   `localaccounts.user.delete --username test`
   The user is deleted.

Monitor Health Status and Statistics in vCenter

You can monitor the hardware health status of vCenter by using the API commands in the appliance shell. You can also monitor the health status of the update component for information about available patches.

You can view the status of the hardware components such as memory, CPU, storage, and network, as well as the update component that shows if the software packages are up to date according to the last check for available patches.
A particular health status can be green, yellow, orange, red, or gray. For more information, see View vCenter Health Status.

For a complete list of the API commands that you can use for monitoring statistics and health of the vCenter system, see API Commands in Appliance Shell.

1. Access the appliance shell and log in.
   The user name that you use to log in can be of a user with an operator, administrator, or super administrator user role.
2. View the health status of a particular component.
   - To view the health of the memory in vCenter, run the `mem.health.get` command.
   - To view the health of the storage in vCenter, run the `storage.health.get` command.
   - To view the health of the swap in vCenter, run the `swap.health.get` command.
   - To view the health of the update component in vCenter, run the `softwarepackages.health.get` command.

     Important:
     If you do not perform regular checks for available patches, the health status of the update component might become out-of-date. For information about checking for vCenter patches and enabling automatic checks for vCenter patches, see *vSphere Upgrade*.
   - To view the overall health of the vCenter system, run the `health.system.get` command.
3. To view statistics about a particular hardware component, run the respective command.
   For example, to view storage statistics for each logical disk, run the `storage.stats.list` command.

Using the Direct Console User Interface to Configure vCenter

After you deploy vCenter, you can reconfigure the network settings and enable access to the Bash shell for troubleshooting. To access the Direct Console User Interface, you must log in as root.

The home page of the Direct Console User Interface contains a link to the support bundle of the vCenter. The link to the support bundle is of the type https://*appliance-host-name*:443/appliance/support-bundle.

Log In to the Direct Console User Interface

The Direct Console User Interface lets you interact with vCenter locally by using text-based menus.

1. From the vSphere Client, navigate to the host and click **Configure** > **Services**. Confirm that the SSH and Direct Console User Interface services are running.
2. Open an SSH client and connect to the ESX host.
3. Log in with the root account.
4. Enter `DCUI` to start the Direct Console User Interface.
5. Click inside the console window and press F2 to customize the system.
6. Type the password for the root user and press Enter.

   Important:
   If you enter invalid credentials thrice, the root account is locked for five minutes.

You logged in to the Direct Console User Interface. You can change the password of the root user, edit the network settings, and enable access to the vCenter appliance Bash shell.

Change the Password of the Root User

To prevent unauthorized access to the vCenter Direct Console User Interface, you can change the password of the root user.

The default root password for the vCenter instance is the password you enter during deployment.

Important:
The password for the root account of vCenter expires after 90 days. You can change the expiry time for an account by logging as root to the vCenter Bash shell, and running `chage -M number_of_days -W warning_until_expirationuser_name`. To increase the expiration time of the root password to infinity, run the `chage -M -1 -E -1 root` command.

1. Log in to the Direct Console User Interface.
2. Select **Configure Password** and press Enter.
3. Type the old password of the root user, and press Enter.
4. Set up the new password and press Enter.
5. Press Esc until you return to the main menu of the Direct Console User Interface.

You changed the password of the root user of the appliance.

Configure the Management Network of vCenter

The vCenter instance can obtain networking settings from a DHCP server, or use static IP addresses. You can change the networking settings of vCenter from the Direct Console User Interface. You can change the IPv4, IPv6, and DNS configuration.

To change the IP address of the vCenter instance, verify that the system name is an FQDN. If, during deployment you set an IP address as a system name, you cannot change the IP address after the deployment. The system name is always used as a primary network identifier.

1. Log in to the Direct Console User Interface of vCenter.
2. Select **Configure Management Network** and press Enter.
3. Change the IPv4 settings from **IP Configuration**.

Option	Description
Use dynamic IP address and network configuration	Obtains networking settings from a DHCP server if one is available on your network
Set static IP address and network configuration	Sets static networking configuration

4. Change the IPv6 settings from **IPv6 Configuration**.

Option	Description
Enable IPv6	Enables or disables IPv6
Use DHCP stateful configuration	Uses a DHCP server to obtain IPv6 addresses and networking settings
Use ICMP stateless configuration	Uses a Stateless Address Autoconfiguration (SLAAC) to obtain IPv6 addresses and network settings

5. Change the DNS settings from **DNS Configuration**.

Option	Description
Obtain DNS server address and hostname automatically	Obtains the DNS server address and host name automatically. Use this option if the IP settings are obtained automatically from a DHCP server.
Use the following DNS server address and hostname	Sets the static IP address and host name for the DNS server.

6. Set custom DNS suffixes from **Custom DNS Suffixes**.
   If you do not specify any suffixes, a default suffix list is derived from the local domain name.
7. Press Esc until you return to the main menu of the Direct Console User Interface.

Restart the Management Network of vCenter

Restart the management network of vCenter to restore the network connection.

1. Log in to the Direct Console User Interface of vCenter.
2. Select **Restart Management Network** and press Enter.
3. Press F11.

Enable Access to the Bash Shell

You can use the Direct Console User Interface to enable local and remote access to the Bash shell. Bash shell access enabled through Direct Console User Interface remains enabled for 3600 seconds.

1. Log in to the Direct Console User Interface of vCenter.
2. Select **Troubleshooting Options** and press Enter.
3. From the Troubleshooting Mode Options menu, select to enable either Bash shell or SSH.
4. Press Enter to enable the service.
5. Press Esc until you return to the main menu of the Direct Console User Interface.

Access the vCenter Bash shell for troubleshooting.

Access the Bash Shell for Troubleshooting

Log in to the Bash shell for troubleshooting purposes only.

1. Access the shell using one of the following methods.
   - If you have direct access to the vCenter instance, press Alt+F1.
   - If you want to connect remotely, use SSH or another remote console connection to start a session.
2. Enter a user name and password.
3. In the shell, enter the command `pi shell` or `shell` to access the Bash shell.

vSphere Authentication

The *vSphere Authentication* documentation provides information to help you perform common tasks such as certificate management and vCenter Single Sign-On configuration.

At VMware, we value inclusion. To foster this principle within our customer, partner, and internal community, we create content using inclusive language.

vSphere Authentication explains how you can manage certificates for vCenter and related services, and set up authentication with vCenter Single Sign-On.

Table 69: vSphere Authentication Highlights

Topics	Content Highlights
Getting Started with Authentication	• Managing authentication services. • Managing vCenter using the vCenter Management Interface.
vSphere Security Certificates	• Certificate model, and options for replacing certificates. • Replace certificates from the UI (simple cases). • Replace certificates using the Certificate Manager utility. • Replace certificates using the CLI (complex situations). • Certificate management CLI reference.
vSphere Authentication with vCenter Single Sign-On	• Architecture of the authentication process. • How to add identity sources so users in your domain can authenticate. • Two-factor authentication. • Managing users, groups, and policies. • vCenter Identity Provider Federation

Related Documentation

A companion document, *vSphere Security*, describes available security features and the measures that you can take to safeguard your environment from attack. That document also explains how you can set up permissions, and includes a reference to privileges.

In addition to these documents, VMware publishes the *vSphere Security Configuration Guide* (formerly known as the *Hardening Guide*) for each release of vSphere, accessible at https://core.vmware.com/security. The *vSphere Security Configuration Guide* contains guidelines on security settings that can or should be set by the customer, and security settings delivered by VMware that should be audited by the customer to ensure that they are still set to default.

Intended Audience

This information is intended for administrators who want to configure vCenter authentication and manage certificates. The information is written for experienced Linux system administrators who are familiar with virtual machine technology and data center operations.

Getting Started with vSphere Certificate Management and Authentication

vSphere provides common infrastructure services to manage certificates for both vCenter and ESX components, and to manage authentication with vCenter Single Sign-On.

How Do You Manage vSphere Certificates

By default, vSphere enables you to provision vCenter components and ESX hosts with VMware Certificate Authority (VMCA) certificates. You can also use custom certificates, which are stored in the VMware Endpoint Certificate Store (VECS). For more information, see What Options Do You Have to Manage vSphere Certificates.

What Is vCenter Single Sign-On

vCenter Single Sign-On allows vSphere components to communicate with each other through a secure token mechanism. vCenter Single Sign-On uses specific terms and definitions that are important to understand.

Table 70: vCenter Single Sign-On Glossary

Term	Definition
Principal	An entity that can be authenticated, such as a user.
Identity Provider	A service that manages identity sources and authenticates principals. Examples: Microsoft Active Directory Federation Services (AD FS) and vCenter Single Sign-On.
Identity Source (Directory Service)	Stores and manages principals. Principals consist of a collection of attributes about a user or a service account such as name, address, email, and group membership. Examples: Microsoft Active Directory and VMware Directory Service (vmdir).
Authentication	The means of determining whether someone or something is, in fact, who or what it declares itself to be. For example, users are authenticated when they provide their credentials, such as user name and correct password, and so on.
Authorization	The process of verifying what objects principals have access to.
Token	A signed collection of data comprising the identity information for a given principal. A token might include not only basic information about the principal such as email address and full name, but also, depending on the token type, the principal's groups and roles.
vmdir	VMware Directory Service. The internal (local) LDAP repository in vCenter that contains user identities, groups, and configuration data.
OAuth 2.0	An open authorization standard that enables the exchange of information among principals and web services without exposing principals' credentials.
OpenID Connect (OIDC)	Authentication protocol based on OAuth 2.0 that augments OAuth with user-identifying information. It is represented by the ID token that the authorization server returns together with the access token during OAuth authentication. vCenter uses OIDC capabilities when interacting with Active Directory Federation Services (AD FS), Okta, Microsoft Entra ID, and PingFederate.
System for Cross-domain Identity Management (SCIM)	The standard for automating the exchange of user identity information between identity domains or IT systems.
VMware Identity Services	Starting in version 8.0 Update 1, VMware Identity Services is a built-in container within vCenter that you can use for identity federation to external identity providers. It serves as an independent identity broker within vCenter and comes with its own set of APIs. Currently, VMware Identity Services support Okta, Microsoft Entra ID, and PingFederate as external identity providers.

Term	Definition
Tenant	A VMware Identity Services concept. A tenant provides a logical separation of data from other tenants' data in the same virtual environment.
JSON Web Token (JWT)	A token format defined by the OAuth 2.0 specification. A JWT token carries authentication and authorization information about a principal.
Relying party	A relying party "relies" on the authorization server, VMware Identity Services, or AD FS, for identity management. For example, through federation, vCenter establishes relying party trust to VMware Identity Services or AD FS.
Security Assertion Markup Language (SAML)	An XML-based open standard for exchanging authentication and authorization data between parties that is used by vCenter. Principals obtain a SAML token from vCenter Single Sign-On and then send it to the vSphere Automation API endpoint for a session identifier.

What Are the vCenter Single Sign-On Authentication Types

vCenter Single Sign-On uses different types of authentication, depending on whether the built-in vCenter identity provider or an external identity provider is involved.

Table 71: vCenter Single Sign-On Authentication Types

Authentication Type	What Acts as the Identity Provider?	Does vCenter Handle the Password?	Description
Token-Based Authentication	External identity provider. For example, AD FS.	No	vCenter contacts the external identity provider through a particular protocol and obtains a token, which represents a particular user identity.
Simple Authentication	vCenter	Yes	The user name and password are passed directly to vCenter, which validates the credentials through its identity sources.

vSphere Authentication Options

In vSphere 9.0 and later, external identity provider federation is the preferred authentication method for vCenter. With VCF 9.0 we are moving towards a modern authentication which leverages federation of vCenter with an external IDP provider. Native vCenter features for multi-factor authentication are deprecated in favor of leveraging the external identity providers capabilities or multi-factor authentication.

The vCenter authentication will transparently delegate the authentication call to the federated IDP which performs the authentication by all supported means including multi-factor authentication, and then return a token to vCenter which is used for authentication. All multi-factor authentication options including the token validity time can be configured at the external identity provider settings. For more information on VCF Single Sign-On, see Configuring VCF Single Sign-On.

vCenter supports the following external identity providers:

- **ADFS** (vSphere 7.0 and later)
- **OKTA** (vSphere 8.0 Update 1 and later)
- **Microsoft Entra ID**, formerly called Azure AD (vSphere 8.0 Update 2 and later)
- **PingFederate** (starting in vSphere 8.0 Update 3)

Consider the version and timelines when you plan your migration to a federated vCenter authentication.

Two-Factor Authentication Methods

Government agencies or large enterprises often require two-factor authentication. vSphere supports the following two-factor authentication method.

External Identity Provider Federation	With external identity provider federation, you can use the authentication mechanisms supported by the external identity provider, including multi-factor authentication.

Specifying a vCenter Non-default Authentication Method

You can set up a non-default authentication method from the vSphere Client, or by using the `sso-config` script.

Combining vCenter Authentication Methods

You can activate or deactivate each authentication method separately by using `sso-config`. Leave user name and password authentication enabled initially, while you are testing a two-factor authentication method, and set only one authentication method to enabled after testing.

Managing vCenter Certificates

You manage vCenter certificates from the vSphere Client, or by using an API, scripts, or CLIs.

The following table describes the interfaces that you can use to manage vCenter certificates.

Table 72: Interfaces for Managing vCenter Certificates

Interface	Description
vSphere Client	Web interface (HTML5-based client). See Managing Certificates Using the vSphere Client.
vSphere Automation API	See *VMware vSphere Automation SDKs Programming Guide*.
Certificate Management utility	Command-line tool that supports Certificate Signing Request (CSR) generation and certificate replacement. See Managing Certificates Using the vSphere Certificate Manager Utility.
CLIs for managing certificate and directory services	Set of commands for managing certificates, the VMware Endpoint Certificate Store (VECS), and VMware Directory Service (vmdir). See vSphere Certificates and Services CLI Command Reference.

Manage vCenter Certificates Using the vSphere Client

You can manage vCenter certificates from the vSphere Client.

1. Log in to a vCenter as a user with administrator privileges in the local vCenter Single Sign-On domain.
   The default domain is vsphere.local.
2. Select **Administration**.
3. Under **Certificates**, click **Certificate Management**.
   Certificate tabs for the different types of certificates appear.
4. Perform certificate tasks, such as viewing certificate details, renewing or refreshing a certificate, and adding a Trusted Root certificate.
   For more information, see Managing Certificates Using the vSphere Client.

Manage vCenter Certificates Using CLIs

vCenter includes CLIs for generating Certificate Signing Requests (CSRs), managing certificates, and managing services.

Enable SSH login to vCenter. You can use the **Access** tab in the vCenter Management Interface (`https://vcenter_server_ip:5480`) for SSH login activation and deactivation.

For example, you can use the `certool` command to generate CSRs and to replace certificates.

Use the CLIs for management tasks that the vSphere Client does not support, or to create custom scripts for your environment.

Table 73: CLIs for Managing vCenter Certificates and Associated Services

CLI	Description	Links
`certool`	Generate and manage certificates and keys. Part of the VMware Certificate Authority (VMCA).	certool Initialization Commands Reference
`vecs-cli`	Manage the contents of VMware Certificate Store instances. Part of VMware Authentication Framework Daemon (VMAFD).	vecs-cli Command Reference
`dir-cli`	Create and update certificates in VMware Directory Service. Part of VMAFD.	dir-cli Command Reference
`sso-config`	Update Security Token Service (STS) certificates.	Replace a vCenter STS Certificate Using the Command Line
`service-control`	Command for starting, stopping, and listing services.	Run this command to stop services before running other CLI commands.

1. Log in to the vCenter shell.

   Usually, you have to be the root user. See vSphere Certificates and Services CLI Command Reference for details.

2. Access a CLI at one of the following default locations.

   The required privileges depend on the task that you want to perform. Sometimes, you are prompted for the password twice to safeguard sensitive information.

   ```
   /usr/lib/vmware-vmafd/bin/vecs-cli
   /usr/lib/vmware-vmafd/bin/dir-cli
   /usr/lib/vmware-vmca/bin/certool
   /opt/vmware/bin/sso-config.sh
   ```

   The `service-control` command does not require that you enter the path.

   For more information, see Manual vSphere Certificate Replacement.

Managing vCenter Authentication Services

You manage authentication services from the vSphere Client, or by using the CLI. You can also manage the vCenter Identity Provider Federation configuration process by using an API.

You can manage vCenter authentication using different interfaces.

Table 74: Interfaces for Managing vCenter Authentication Services

Interface	Description
vSphere Client	Web interface (HTML5-based client).
API	Manage the vCenter Identity Provider Federation configuration process.
`sso-config`	Command-line utility for configuring the vCenter built-in identity provider.

Manage vCenter Authentication Services Using the vSphere Client

You can manage vCenter authentication services from the vSphere Client.

1. Log in to a vCenter as a user with administrator privileges in the local vCenter Single Sign-On domain.
   The default domain is vsphere.local.
2. Select **Administration**.
3. Under **Single Sign On**, click **Configuration** to manage identity providers and configure password and lockout policies.
   For more information, see vSphere Authentication with vCenter Single Sign-On.

Manage vCenter Authentication Services Using Scripts

vCenter includes a utility, `sso-config`, for managing authentication services.

Enable SSH login to vCenter. You can use the **Access Settings** tab in the vCenter Management Interface (`https://vcenter_server_ip:5480`) for SSH login activation and deactivation.

Use the `sso-config` utility for management tasks that the vSphere Client does not support, or to create custom scripts for your environment.

Table 75: CLIs for Managing Authentication and Associated Services

CLI	Description	Links
`sso-config`	Command-line utility for configuring the vCenter built-in identity provider.	Refer to the `sso-config` help by running `sso-config.sh -help`, or see the Broadcom knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=67304 for usage examples.
`service-control`	Command for starting, stopping, and listing services.	Run this command to stop services before running other CLI commands. The `service-control` command does not require that you specify the path.

1. Log in to the vCenter shell.
   Usually, you have to be the root or Administrator user. See vSphere Certificates and Services CLI Command Reference for details.
2. Access the `sso-config` utility at following default location.
   ```
   /opt/vmware/bin/sso-config.sh
   ```
   The required privileges depend on the task that you want to perform. Sometimes, you are prompted for the password twice to safeguard sensitive information.

Managing the vCenter

You can manage the vCenter from the vCenter Management Interface or from the vCenter shell.

For more information about managing vCenter, see *vCenter Configuration*.

Table 76: Interfaces for Managing the vCenter

Interface	Description
vCenter Management Interface	Use this interface to reconfigure the system settings. See Manage vCenter Using the Management Interface.
vCenter shell	Use this command-line interface to perform service management operations on VMCA, VECS, and VMDIR. See Managing Certificates Using the vSphere Certificate Manager Utility and vSphere Certificates and Services CLI Command Reference.

Manage vCenter Using the Management Interface

You can use the vCenter Management Interface to configure the system settings.

Settings in the vCenter Management Interface include time synchronization, network settings, and SSH login settings. You can also change the root password, join the appliance to an Active Directory domain, and leave an Active Directory domain.

> **Note:**
> Under the **Networking** pane, the virtual NIC 0 is reserved for management traffic. You cannot reassign the traffic from NIC 0 to another NIC. If you are using VCHA, this traffic uses NIC 1. You can add NICs to the vCenter appliance. See the Broadcom knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2147155.

1. In a browser, go to the web interface at `https://vcenter_server_ip:5480`.
2. If a warning message about an untrusted SSL certificate appears, resolve the issue based on your company security policy and the browser that you are using.
3. Log in as root.
   The default root password is the root password that you set when deploying the vCenter.

You see the Summary page of the vCenter Management Interface.

Manage vCenter Using the vCenter Shell

You can use service management utilities and CLIs from the vCenter shell. You can use TTY1 to log in to the console, or can use SSH to connect to the shell.

1. Activate SSH login if necessary.
   a) Log in to the vCenter Management Interface at https://*vcenter_server_ip*:5480.
   b) In the Navigator, select **Access** and click **Edit**.
   c) Toggle on **Activate SSH Login** and click **OK**.
   You can follow the same steps to activate the Bash shell for the vCenter.
2. Access the shell.
   - If you have direct access to the vCenter console, select **Log in**, and press Enter.
   - To connect remotely, use SSH or another remote console connection to start a session to the vCenter.
3. Log in as root with the password that you set when you initially deployed the vCenter.
   If you changed the root password, use the new password.

vSphere Security Certificates

vSphere provides security by using certificates to encrypt communications, authenticate services, and sign tokens.

How Does vSphere Use Certificates

vSphere uses certificates to:

- Encrypt communications between two nodes, such as a vCenter and an ESX host.
- Authenticate vSphere services.
- Perform internal actions such as signing tokens.

What is the VMware Certificate Authority

vSphere's internal certificate authority, VMware Certificate Authority (VMCA), provides all the certificates necessary for vCenter and ESX. VMCA is installed on every vCenter instance, immediately securing the solution without any other modification. Keeping this default configuration provides the lowest operational overhead for certificate management. vSphere provides a mechanism to renew these certificates in the event they expire. Starting with VCF 9.1, the VMCA and

solution certificates that are due to expire within two years are automatically renewed, and replaced when you upgrade your vCenter to major or minor version. A new VMCA root certificate is provisioned if the expiry threshold is met.

vSphere also provides a mechanism to replace certain certificates with your own certificates. However, replace only the SSL certificate that provides encryption between nodes, to keep your certificate management overhead low.

What Options Do You Have to Manage vSphere Certificates

The following options are recommended for managing certificates.

Table 77: Recommended Options for Managing vSphere Certificates

Mode	Description	Advantages
VMCA Default Certificates	VMCA provides all the certificates for vCenter and ESX hosts.	Simplest and lowest overhead. VMCA can manage the certificate life cycle for vCenter and ESX hosts.
VMCA Default Certificates with External SSL Certificates (Hybrid Mode)	You replace the vCenter SSL certificates, and allow VMCA to manage certificates for solution users and ESX hosts. Optionally, for high-security conscious deployments, you can replace the ESX host SSL certificates as well.	Simple and secure. VMCA manages internal certificates but you get the benefit of using your corporate-approved SSL certificates, and having those certificates trusted by your browsers.

What Tools Are Available to Replace vSphere Certificates

You can use the following options to replace the existing certificates.

Table 78: Different Approaches to vSphere Certificate Replacement

Option	See
Use the vSphere Client.	Managing Certificates Using the vSphere Client
Use the vSphere Automation API to manage the life cycle of certificates.	*VMware vSphere Automation SDKs Programming Guide*
Use the vSphere Certificate Manager utility from the command line.	Managing Certificates Using the vSphere Certificate Manager Utility
Use CLI commands for manual certificate replacement.	vSphere Certificates and Services CLI Command Reference

vSphere Certificate Requirements for Different Solution Paths

Certificate requirements depend on whether you use the VMware Certificate Authority (VMCA) as an intermediate certificate authority or you use custom certificates. Requirements are also different for machine certificates.

Before you begin to change certificates, ensure that all nodes in your vSphere environment are time synchronized.

> **Note:**
> vSphere deploys only RSA certificates for server authentication and does not support generating ECDSA certificates. vSphere verifies ECDSA certificates presented by other servers. For example, if vSphere connects to a syslog server and the syslog server has an ECDSA certificate, vSphere supports verifying that certificate.

Requirements for All Imported vSphere Certificates

- Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded). The vSphere Client and API still accept a key size up to 16384 bits when generating the Certificate Signing Request.

Note:
In vSphere 8.0, you can only generate CSRs with a minimum key length of 3072 bits when using the vSphere Client or the vSphere Certificate Manager. vCenter still does accept custom certificates bearing a key length of 2048 bits. In vSphere 8.0 Update 1 and later, you can use the vSphere Client to generate a CSR with a key length of 2048 bits.

Note:
vSphere's FIPS certificate only validates RSA key sizes of 2048 bits and 3072 bits.

- PEM format. VMware supports PKCS8 and PKCS1 (RSA keys). When you add keys to VECS, they are converted to PKCS8.
- x509 version 3
- SubjectAltName must contain DNS Name=*machine_FQDN*
- CRT format
- Contains the following Key Usages: Digital Signature, Non-Repudiation, Key Encipherment.
- Contains the following Key Usages: Digital Signature, Key Encipherment.
- Exempting the vpxd-extension solution user certificate, Extended Key Usage can be either empty or can contain Server Authentication.

vSphere does not support the following certificates.

- Certificates with wildcards.
- The algorithms md2WithRSAEncryption, md5WithRSAEncryption, RSASSA-PSS, dsaWithSHA1, ecdsa_with_SHA1, and sha1WithRSAEncryption are not supported.
- When creating a custom machine SSL certificate for vCenter, Server Authentication and Client Authentication are not supported, and must be removed when using the Microsoft Certificate Authority (CA) templates. For more information, see the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2112009.

vSphere Certificate Compliance to RFC 2253

The certificate must be in compliance with RFC 2253.

If you do not generate CSRs using vSphere Certificate Manager, ensure that the CSR includes the following fields.

String	X.500 AttributeType
CN	`commonName`
L	`localityName`
ST	`stateOrProvinceName`
O	`organizationName`
OU	`organizationalUnitName`
C	`countryName`
STREET	`streetAddress`
DC	`domainComponent`
UID	`userid`

If you generate CSRs using vSphere Certificate Manager, you are prompted for the following information, and vSphere Certificate Manager adds the corresponding fields to the CSR file.

- The password of the administrator@vsphere.local user, or for the administrator of the vCenter Single Sign-On domain that you are connecting to.
- Information that vSphere Certificate Manager stores in the `certool.cfg` file. For most fields, you can accept the default or provide site-specific values. The FQDN of the machine is required.
  - Password for administrator@vsphere.local
  - Two-letter country code
  - Company name

- Organization name
- Organization unit
- State
- Locality
- IP address (optional)
- Email (optional)
- Host name, that is, the fully qualified domain name of the machine for which you want to replace the certificate. If the host name does not match the FQDN, certificate replacement does not complete correctly and your environment might end up in an unstable state.
- IP address of the vCenter node on which you run vSphere Certificate Manager.
- OU (organizationalUnitName) (optional)

Certificate Requirements When Using VMCA as an Intermediate Certificate Authority

When you use VMCA as an intermediate CA, the certificates must meet the following requirements.

Certificate Type	Certificate Requirements

Root certificate	• You can use vSphere Certificate Manager to create the CSR. See Generate CSR Using the Certificate Manager and Prepare Root Certificate (Intermediate CA).
	• If you prefer to create the CSR manually, the certificate that you send to be signed must meet the following requirements.
	– Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded)
	– PEM format. VMware supports PKCS8 and PKCS1 (RSA keys). When keys are added to VECS, they are converted to PKCS8.
	– x509 version 3
	– The CA extension must be set to true for root certificates, and cert sign must be in the list of requirements. For example:
	`basicConstraints = critical,CA:true`
	`keyUsage = critical,digitalSignature,keyCertSign`
	– CRL signing must be enabled.
	– Extended Key Usage can be either empty or contain Server Authentication.
	– No explicit limit to the length of the certificate chain. VMCA uses the OpenSSL default, which is 10 certificates.
	– Certificates with wildcards or with more than one DNS name are not supported.
	– You cannot create subsidiary CAs of VMCA.
	See the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2112009, Creating a Microsoft Certificate Authority Template for SSL certificate creation in vSphere 6.x, for an example using Microsoft Certificate Authority.

Machine SSL certificate	You can use vSphere Certificate Manager to create the CSR or create the CSR manually. If you create the CSR manually, it must meet the requirements that are listed previously under *Requirements for all Imported vSphere Certificates*. You also have to specify the FQDN for the host.
Solution user certificate	You can use vSphere Certificate Manager to create the CSR or create the CSR manually. **Note:** You must use a different value for Name for each solution user. If you generate the certificate manually, this might show up as **CN** under **Subject**, depending on the tool you use. If you use vSphere Certificate Manager, the tool prompts you for certificate information for each solution user. vSphere Certificate Manager stores the information in `certool.cfg`. For the vpxd-extension solution user, you can either leave Extended Key Usage empty or use "TLS WWW client authentication".

Requirements When Using Custom Certificates

When you want to use custom certificates, the certificates must meet the following requirements.

Certificate Type	Certificate Requirements
Machine SSL certificate	The machine SSL certificate on each node must have a separate certificate from your third-party or enterprise CA. • You can generate the CSR using the vSphere Client or the vSphere Certificate Manager, or create the CSR manually. The CSR must meet the requirements listed previously under *Requirements for all Imported vSphere Certificates*. • For most fields, you can accept the default or provide site-specific values. The FQDN of the machine is required.
Solution user certificate	Each solution user on each node must have a separate certificate from your third-party or enterprise CA. • You can generate the CSRs using vSphere Certificate Manager or prepare the CSR yourself. The CSR must meet the requirements listed previously under *Requirements for all Imported vSphere Certificates*. • If you use vSphere Certificate Manager, the utility prompts you for certificate information for each solution user. vSphere Certificate Manager stores the information in `certool.cfg`. **Note:** You must use a different value for Name for each solution user. A manually generated certificate might show up as **CN** under **Subject**, depending on the tool you use. When later you replace solution user certificates with custom certificates, provide the complete signing certificate chain of the third-party CA. For the vpxd-extension solution user, you can either leave Extended Key Usage empty or use "TLS WWW client authentication".

Note:

Solution users are deprecated in vCenter 9.0 and are being replaced by Service Accounts. For more information, see VCF 9.0 Release Notes.

vSphere Certificate Management

The work that is required for setting up or updating your vSphere certificate infrastructure depends on the requirements in your environment. You must consider whether you are performing a fresh installation or an upgrade, and whether you are considering ESX or vCenter.

Environments That Use VMware Certificate Authority Certificates

VMware Certificate Authority (VMCA) can handle all certificate management. VMCA provisions vCenter components and ESX hosts with certificates that use VMCA as the root certificate authority.

If you do not currently replace VMware certificates, your environment starts using VMCA-signed certificates instead of self-signed certificates.

Environments That Use Custom Certificates

If your company policy requires certificates that are signed by a third-party or enterprise certificate authority, or that require custom certificate information, you have several choices for a fresh installation.

- Have the VMCA root certificate signed by a third-party CA or enterprise CA. Replace the VMCA root certificate with that signed certificate. In this scenario, the VMCA certificate is an intermediate certificate. VMCA provisions vCenter components and ESX hosts with certificates that include the full certificate chain.
- If your company policy does not allow intermediate certificates in the chain, you can replace certificates explicitly. You can use the vSphere Client, vSphere Certificate Manager utility, or perform manual certificate replacement using the certificate management CLIs.

When upgrading an environment that uses custom certificates, you can retain some of the certificates.

- ESX hosts keep their custom certificates during upgrade. Make sure that the vCenter upgrade process adds all the relevant root certificates to the TRUSTED_ROOTS store in VMware Certificate Endpoint Store (VECS) on the vCenter. After the upgrade to vSphere 6.0 or later, you can set the certificate mode to **Custom**. If the certificate mode is VMCA (the default), and you perform a certificate refresh from the vSphere Client, the VMCA-signed certificates replace the custom certificates.
- For an upgrade of a simple vCenter installation to an embedded deployment, vCenter retains custom certificates. After the upgrade, your environment works as before. The existing vCenter and vCenter Single Sign-On certificates are retained. The certificates are used as machine SSL certificates. In addition, VMCA assigns a VMCA-signed certificate to each solution user (collection of vCenter services). The solution user uses this certificate only to authenticate to vCenter Single Sign-On. VMware does not recommend replacing solution user certificates.

vSphere Certificate Interfaces

For vCenter, you can view and replace certificates with the following tools and interfaces.

Table 79: Interfaces for Managing vCenter Certificates

Interface	Use
vSphere Client	Perform common certificate tasks with a graphical user interface.
vSphere Automation API	See *VMware vSphere Automation SDKs Programming Guide*.
vSphere Certificate Manager utility	Perform common certificate replacement tasks from the command line of the vCenter installation.
vSphere Certificate Management CLIs	Perform all certificate management tasks with `dir-cli`, `certool`, and `vecs-cli`.
`sso-config` utility	Perform STS certificate management from the command line of the vCenter installation.
PowerCLI 12.4 or later (also requires vSphere 7.0 or later)	Perform trusted certificate store management, manage vCenter Machine SSL certificates, and manage ESX Machine SSL certificates.

For ESX, you perform certificate management from the vSphere Client. VMCA provisions certificates and stores them locally on the ESX host. VMCA does not store ESX host certificates in VMDIR or in VECS. See the *vSphere Security* documentation.

Supported vCenter Certificates

For vCenter and related machines and services, the following certificates are supported:

- Certificates that are generated and signed by VMware Certificate Authority (VMCA).
- Custom certificates.
  - Enterprise certificates that are generated from your own internal PKI.
  - Third-party CA-signed certificates that are generated by an external PKI such as Verisign, GoDaddy, and so on.

Self-signed certificates that were created using OpenSSL in which no Root CA exists are not supported.

Replacing vSphere Certificates

You can perform different types of certificate replacement depending on your company policy and requirements for the system that you are configuring. You can perform certificate replacement from the vSphere Client, by using the vSphere Certificate Manager utility, or manually by using the CLIs included with your installation.

The VMware Certificate Authority (VMCA) is included in each vCenter deployment. VMCA provisions each node, each vCenter solution user, and each ESX host with a certificate that is signed by VMCA as the certificate authority.

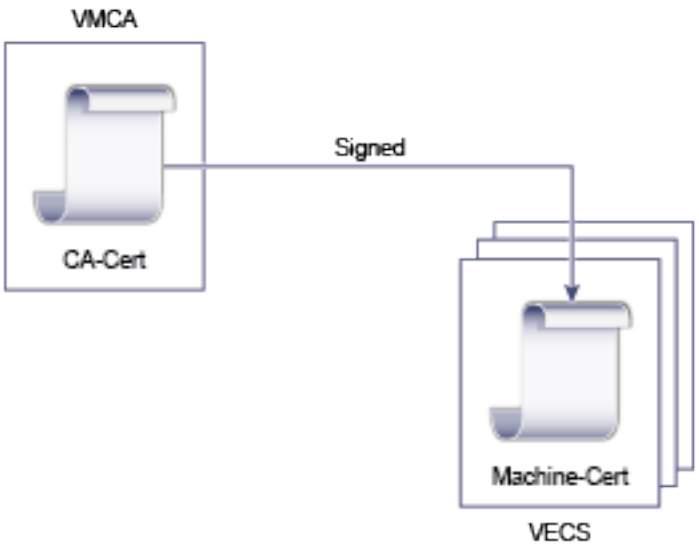
You can replace the default certificates. For vCenter components, you can use a set of command-line tools included in your installation. You have several options.

Note:
If your vCenter is linked to NSX Manager, and you replace vCenter certificates, you must update the thumbprint of the vCenter compute manager. See the topic titled "Add a Compute Manager" in *NSX Administrator Guide*.

Replacing Certificates with VMCA-Signed Certificates

If your VMCA certificate expires or you want to replace it for other reasons, you can use the certificate management CLIs to perform that process. By default, the VMCA root certificate expires after 10 years, and all certificates that VMCA signs expire when the root certificate expires, that is, after a maximum of 10 years. Starting with VCF 9.1, the VMCA and solution certificates that are due to expire within two years are automatically renewed and replaced when you upgrade your vCenter to major or minor version. A new VMCA root certificate is provisioned if the expiry threshold is met.

Figure 27: Certificates Signed by VMCA Are Stored in VECS



You can use the following vSphere Certificate Manager options:

- Replace Machine SSL Certificate with VMCA Certificate
- Replace Solution User Certificate with VMCA Certificate

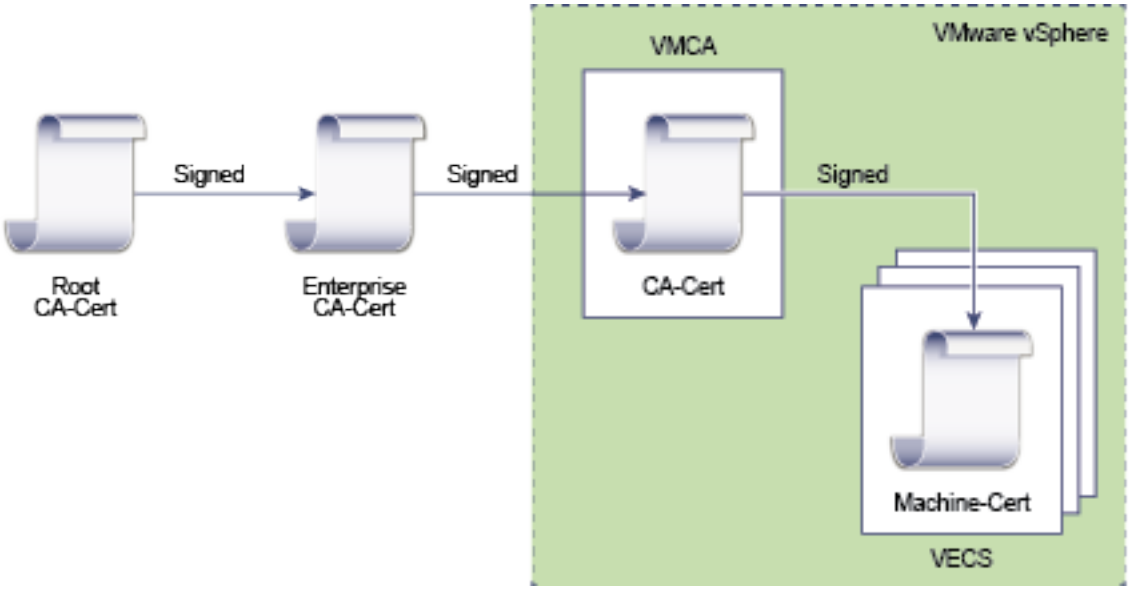
For manual certificate replacement, see Replace Existing VMCA-Signed Certificates with New VMCA-Signed Certificates Using the CLI.

Making VMCA an Intermediate Certificate Authority

You can replace the VMCA root certificate with a certificate that is signed by an enterprise certificate authority (CA), or a third-party CA. VMCA signs the custom root certificate each time it provisions certificates, making VMCA an intermediate CA.

Note:
If you perform a fresh install with a vCenter, replace the VMCA root certificate before you add ESX hosts. If you do, VMCA signs the whole chain, and you do not have to generate new certificates.

Figure 28: Certificates Signed by a Third-Party or Enterprise CA Use VMCA as an Intermediate CA



You can use the following vSphere Certificate Manager options:

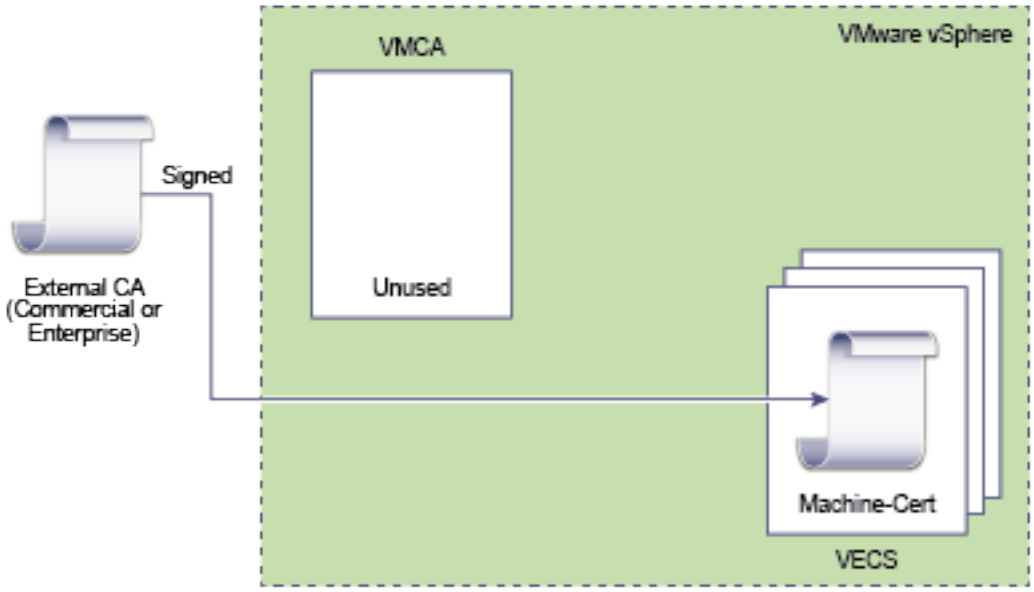
- Replace VMCA Root Certificate with Custom Signing Certificate and Replace All Certificates
- Replace Machine SSL Certificate with VMCA Certificate (multi-node enhanced linked mode deployment)
- Replace Solution User Certificate with VMCA Certificate (multi-node enhanced linked mode deployment)

For manual certificate replacement, see Make VMCA Into an Intermediate Certificate Authority Using the CLI.

Replacing VMCA-Signed Certificates with Custom Certificates

You can replace the existing VMCA-signed certificates with custom certificates. If you use that approach, you are responsible for all certificate provisioning and monitoring.

Figure 29: External Certificates Are Stored Directly in VECS



You can use the following vSphere Certificate Manager options:

- Replace Machine SSL Certificate with Custom Certificate
- Replace Solution User Certificates with Custom Certificates

For manual certificate replacement, see Replace Certificates with Custom Certificates Using the CLI.

You can also use the vSphere Client to generate a CSR for a machine SSL certificate (custom), and replace the certificate after the CA returns it. See Generate Certificate Signing Request for Machine SSL Certificate Using the vSphere Client (Custom Certificates).

Using the Hybrid Approach to Certificate Deployment

In the hybrid approach, you can have VMCA supply some of the certificates, but use custom certificates for other parts of your infrastructure. For example, because solution user certificates are used only to authenticate to vCenter Single Sign-On, consider having VMCA provision those certificates. Replace the machine SSL certificates with custom certificates to secure all SSL traffic.

Company policy often does not allow intermediate CAs. For those cases, hybrid deployment is a good solution. It minimizes the number of certificates to replace, and secures all traffic. The hybrid deployment leaves only internal traffic, that is, solution user traffic, to use the default VMCA-signed certificates.

For more information, see the blog post titled *New Product Walkthrough - Hybrid vSphere SSL Certificate Replacement* at https://blogs.vmware.com/vsphere/2017/01/walkthrough-hybrid-ssl-certificate-replacement.html.

ESX Certificate Replacement

For ESX hosts, you can change certificate provisioning behavior from the vSphere Client. See the *vSphere Security* documentation for details.

Table 80: ESX Certificate Replacement Options

Option	Description
VMware Certificate Authority mode (default)	When you renew certificates from the vSphere Client, VMCA issues the certificates for the hosts. If you changed the VMCA root certificate to include a certificate chain, the host certificates include the full chain.
Custom Certificate Authority mode	Allows you to update and use certificates manually that are not signed or issued by VMCA.
Thumbprint mode	Can be used to retain 5.5 certificates during refresh. Use this mode only temporarily in debugging situations.

Where vSphere Uses Certificates

The VMware Certificate Authority (VMCA) provisions your environment with certificates. Certificates include machine SSL certificates for secure connections, solution user certificates for authentication of services to vCenter Single Sign-On, and certificates for ESX hosts.

The following certificates are in use.

Table 81: Certificates in vSphere

Certificate	Provisioned	Comments
ESX certificates	VMCA (default)	Stored locally on ESX host.
Machine SSL certificates	VMCA (default)	Stored in VMware Endpoint Certificate Store (VECS).
Solution user certificates	VMCA (default)	Stored in VECS.
vCenter Single Sign-On SSL signing certificate	Provisioned during installation.	Manage this certificate from the command line. **Note:** Do not change this certificate in the filesystem or unpredictable behavior results.
VMware Directory Service (VMDIR) SSL certificate	Provisioned during installation.	In vSphere 6.5 and later, the machine SSL certificate is used as the vmdir certificate.

Certificate	Provisioned	Comments
SMS self-signed certificates	Provisioned during registration of the IOFilter Provider.	In vSphere 7.0 and later, SMS self-signed certificates are stored in `/etc/vmware/ssl/iofilter vp_castore.pem`. Before vSphere 7.0, SMS self-signed certificates are stored in `/etc/vm ware/ssl/castore.pem`. In addition, the SMS Store can also store VVOL VASA Provider's (version 4.0 and earlier) self-signed certificates when retainVasaProviderCertificate=True.

ESX Certificates

ESX certificates are stored locally on each host in the `/etc/vmware/ssl` directory. ESX certificates are provisioned by VMCA by default, but you can use custom certificates instead. ESX certificates are provisioned when the host is first added to vCenter and when the host reconnects. For more information, see the *vSphere Security* documentation.

Machine SSL Certificates

The machine SSL certificate for each node is used to create an SSL socket on the server side. SSL clients connect to the SSL socket. The certificate is used for server verification and for secure communication such as HTTPS or LDAPS.

Each vCenter node has its own machine SSL certificate. All services that are running on a vCenter node use the machine SSL certificate to expose their SSL endpoints.

The following services use the machine SSL certificate.

- The reverse proxy service. SSL connections to individual vCenter services always go to the reverse proxy. Traffic does not go to the services themselves.
- The vCenter service (vpxd).
- The VMware Directory Service (vmdir).

VMware products use standard X.509 version 3 (X.509v3) certificates to encrypt session information. Session information is sent over SSL between components.

Solution User Certificates

A solution user encapsulates one or more vCenter services. Each solution user must be authenticated to vCenter Single Sign-On. Solution users use certificates to authenticate to vCenter Single Sign-On through SAML token exchange.

A solution user presents the certificate to vCenter Single Sign-On when it first has to authenticate, after a reboot, and after a timeout has elapsed. The timeout (Holder-of-Key Timeout) can be set from the vSphere Client and defaults to 2592000 seconds (30 days).

For example, the vpxd solution user presents its certificate to vCenter Single Sign-On when it connects to vCenter Single Sign-On. The vpxd solution user receives a SAML token from vCenter Single Sign-On and can then use that token to authenticate to other solution users and services.

The following solution user certificate stores are included in VECS:

- `machine`: Used by the license server and the logging service.

  Note:
  The machine solution user certificate has nothing to do with the machine SSL certificate. The machine solution user certificate is used for the SAML token exchange. The machine SSL certificate is used for secure SSL connections for a machine.
- `vpxd`: vCenter service daemon (vpxd) store. vpxd uses the solution user certificate that is stored in this store to authenticate to vCenter Single Sign-On.
- `vpxd-extension`: vCenter extensions store. Includes the Auto Deploy service, inventory service, and other services that are not part of other solution users.
- `vsphere-webclient`: vSphere Client store. Also includes some additional services such as the performance chart service.

- `wcp`: VMware vSphere® with VMware Tanzu™ store. Also used for vSphere Cluster Services.

Internal Certificates

vCenter Single Sign-On certificates are not stored in VECS and are not managed with certificate management tools. As a rule, changes are not necessary, but in special situations, you can replace these certificates.

vCenter Single Sign-On Signing Certificate	The vCenter Single Sign-On service includes an identity provider service that issues SAML tokens that are used for authentication throughout vSphere. A SAML token represents the user's identity, and also contains group membership information. When vCenter Single Sign-On issues SAML tokens, it signs each token with its signing certificate so that clients of vCenter Single Sign-On can verify that the SAML token comes from a trusted source. You can replace this certificate from the CLI. See Replace a vCenter STS Certificate Using the Command Line.
VMware Directory Service SSL Certificate	In vSphere 6.5 and later, the machine SSL certificate is used as the VMware directory certificate.
vSphere Virtual Machine Encryption Certificates	The vSphere Virtual Machine Encryption solution connects with a key server. Depending on how the solution authenticates to the key server, it might generate certificates and store them in VECS. See the *vSphere Security* documentation.

VMware Certificate Authority and VMware Core Identity Services

Core identity services are part of every vCenter system. VMware Certificate Authority (VMCA) is part of every VMware core identity services group. Use the management CLIs and the vSphere Client to interact with these services.

VMware core identity services include several components.

Table 82: Core Identity Services

Service	Description
VMware Directory Service (vmdir)	Identity source that handles SAML certificate management for authentication with vCenter Single Sign-On.
VMware Certificate Authority (VMCA)	Issues certificates for VMware solution users, machine certificates for machines on which services are running, and ESX host certificates. VMCA can be used as is, or as an intermediary certificate authority. VMCA issues certificates only to clients that can authenticate to vCenter Single Sign-On in the same domain.
VMware Authentication Framework Daemon (VMAFD)	Includes the VMware Endpoint Certificate Store (VECS) and several other authentication services. VMware administrators interact with VECS. The other services are used internally.

VMware Endpoint Certificate Store

VMware Endpoint Certificate Store (VECS) serves as a local (client-side) repository for certificates, private keys, and other certificate information that can be stored in a keystore. You can decide not to use VMCA as your certificate authority and certificate signer, but you must use VECS to store all vCenter certificates, keys, and so on. ESX certificates are stored locally on each host and not in VECS.

VECS runs as part of the VMware Authentication Framework Daemon (VMAFD). VECS runs on every vCenter node, and holds the keystores that contain the certificates and keys.

VECS polls VMware Directory Service (vmdir) periodically for updates to the trusted root store. You can also explicitly manage certificates and keys in VECS using `vecs-cli` commands. See vecs-cli Command Reference.

VECS includes the following stores.

Table 83: Stores in VECS

Store	Description
Machine SSL store (MACHINE_SSL_CERT)	• Used by the reverse proxy service on every vSphere node. • Used by the VMware Directory Service (vmdir) on each vCenter node. All services in vSphere 6.0 and later communicate through a reverse proxy, which uses the machine SSL certificate. For backward compatibility, the 5.x services still use specific ports. As a result, some services such as vpxd still have their own port open.
Solution user stores • `machine` • `vpxd` • `vpxd-extension` • `vsphere-webclient` • `wcp`	VECS includes one store for each solution user. The subject of each solution user certificate must be unique, for example, the machine certificate cannot have the same subject as the vpxd certificate. Solution user certificates are used for authentication with vCenter Single Sign-On. vCenter Single Sign-On checks that the certificate is valid, but does not check other certificate attributes. The following solution user certificate stores are included in VECS: • `machine`: Used by the license server and the logging service. **Note:** The machine solution user certificate has nothing to do with the machine SSL certificate. The machine solution user certificate is used for the SAML token exchange. The machine SSL certificate is used for secure SSL connections for a machine. • `vpxd`: vCenter service daemon (vpxd) store. vpxd uses the solution user certificate that is stored in this store to authenticate to vCenter Single Sign-On. • `vpxd-extension`: vCenter extensions store. Includes the Auto Deploy service, inventory service, and other services that are not part of other solution users. • `vsphere-webclient`: vSphere Client store. Also includes some additional services such as the performance chart service. • `wcp`: VMware vSphere® with VMware Tanzu™ store. Also used for vSphere Cluster Services. Each vCenter node includes a `machine` certificate.
Trusted root store (TRUSTED_ROOTS)	Contains all trusted root certificates.
vSphere Certificate Manager Utility backup store (BACKUP_STORE)	Used by VMCA (VMware Certificate Manager) to support certificate revert. Only the most recent state is stored as a backup, you cannot go back more than one step.
Other stores	Other stores might be added by solutions. For example, the Virtual Volumes solution adds an SMS store. Do not modify the certificates in those stores unless Broadcom documentation or a Broadcom Knowledge Base article instructs you to do so. **Note:** Deleting the TRUSTED_ROOTS_CRLS store can damage your certificate infrastructure. Do not delete or modify the TRUSTED_ROOTS_CRLS store.

The vCenter Single Sign-On service stores the token signing certificate and its SSL certificate on disk. You can change the token signing certificate from the CLI.

Some certificates are stored on the file system, either temporarily during startup or permanently. Do not change the certificates on the file system.

Note:
Do not change any certificate files on disk unless instructed by VMware documentation or Knowledge Base Articles. Unpredictable behavior might result otherwise.

Managing vSphere Certificate Revocation

If you suspect that one of your certificates has been compromised, replace all existing certificates, including the VMCA root certificate.

vSphere supports replacing certificates but does not enforce certificate revocation for ESX hosts or for vCenter systems.

Remove revoked certificates from all nodes. If you do not remove revoked certificates, a man-in-the-middle attack might enable compromise through impersonation with the account's credentials.

Replacing vSphere Certificates in Large Deployments

When replacing certificates in deployments with large numbers of vCenter instances, you can use the vSphere Certificate Management utility or replace certificates manually using the CLIs. Some best practices guide the process you choose.

Replacement of Machine SSL Certificates in Environments with Multiple vCenter Instances

If your environment includes multiple vCenter instances, you can replace machine SSL certificates with the vSphere Client or the vSphere Certificate Manager utility, or manually with CLI commands.

Using the vSphere Certificate Manager to Replace Machine SSL Certificates on Multiple vCenter Instances	You run vSphere Certificate Manager on each instance. Depending on the task you perform, you are also prompted for certificate information. See the following topics for details: • Replace VMCA Root Certificate with Custom Signing Certificate and Replace All Certificates Using the Certificate Manager • Replace Machine SSL Certificate with VMCA Certificate (Intermediate CA) Using the Certificate Manager • Replace Solution User Certificates with VMCA Certificates (Intermediate CA) Using the Certificate Manager
Using the CLI to Manually Replace Machine SSL Certificates on Multiple vCenter Instances	For manual certificate replacement, you run the certificate replacement CLI commands on each instance. See the following topics for details: • Replace Machine SSL Certificates with VMCA-Signed Certificates Using the CLI • Replace Machine SSL Certificates (Intermediate CA) Using the CLI • Replace Machine SSL Certificates with Custom Certificates Using the CLI

Replacement of Solution User Certificates in Environments with Multiple vCenter Instances in Enhanced Linked Mode

If your environment includes multiple vCenter instances in enhanced linked mode, follow these steps for replacing solution user certificates.

Note:

ELM is not supported in 9.0.

Note:
When you list solution user certificates in large deployments, the output of `/usr/lib/vmware-vmafd/bin/dir-cli list` includes all solution users from all nodes. Run `/usr/lib/vmware-vmafd/bin/vmafd-cli get-machine-id --server-name localhost` to find the local machine ID for each host. Each solution user name includes the machine ID.

Using the vSphere Certificate Manager to Replace Machine SSL	You run vSphere Certificate Manager on each instance. Depending on the task you perform, you are also prompted for certificate information. See Managing Certificates Using the vSphere Certificate Manager Utility.

Certificates on vCenter Instances in ELM

Using the CLI to Manually Replace Machine SSL Certificates on vCenter Instances in ELM

The high-level steps to manually replace machine SSL certificates on vCenter in ELM include:

1. Generating or requesting a certificate.
   You need the following certificates:
   - A certificate for the machine solution user on each vCenter.
   - A certificate for each of the following solution users on each node:
     - `vpxd` solution user
     - `vpxd-extension` solution user
     - `vsphere-webclient` solution user
     - `wcp` solution user
2. Using the CLI commands to replace the certificates on each node.
   The precise process depends on the type of certificate replacement that you are performing. See the following topics for details:
   - Replace Solution User Certificates with New VMCA-Signed Certificates Using the CLI
   - Replace Solution User Certificates (Intermediate CA) Using the CLI
   - Replace Solution User Certificates with Custom Certificates Using the Certificate Manager

Certificate Replacement in VMware Environments That Include External Solutions

Some solutions, such as VMware Live Recovery or VMware vSphere Replication, are always installed on a different machine than the vCenter instance. If you replace the default machine SSL certificate on the vCenter instance, a connection error results if the solution attempts to connect to the vCenter instance.

You can run the `ls_update_certs` script to resolve the issue. See the Broadcom knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2109074.

Managing Certificates Using the vSphere Client

You can view and manage certificates by using the vSphere Client.

The vSphere Client enables you to perform these management tasks.

- View the machine SSL, VMware Certificate Authority (VMCA) root, Trusted Root, and Security Token Service (STS) certificates.
- Add new Trusted Root certificates, and renew or replace existing machine SSL and STS certificates.
- Generate a custom Certificate Signing Request (CSR) for a machine SSL certificate and replace the certificate when the Certificate Authority returns it.

Most parts of the certificate replacement workflows are supported fully from the vSphere Client. Other certificate replacement workflows are supported by the vSphere Certificate Manager utility. See Managing Certificates Using the vSphere Certificate Manager Utility.

To understand more about options for replacing the default certificates, see Replacing vSphere Certificates.

> **Note:**
>
> If you use the VMCA as an intermediate CA, or use custom certificates, you might encounter significant complexity and the potential for a negative impact to your security, and an unnecessary increase in your operational risk. For more information about managing certificates within a vSphere environment, see the blog post titled *New Product Walkthrough - Hybrid vSphere SSL Certificate Replacement* at https://blogs.vmware.com/vsphere/2017/01/walkthrough-hybrid-ssl-certificate-replacement.html.

Explore Certificate Stores Using the vSphere Client

A VMware Endpoint Certificate Store (VECS) instance is included on each vCenter instance. You can explore the different stores inside the VMware Endpoint Certificate Store from the vSphere Client, including machine SSL, STS, and trusted root certificates.

For most management tasks, you must have the password for the administrator for the local domain account, administrator@vsphere.local or a different domain if you changed the domain during installation.

See VMware Endpoint Certificate Store for details on the different stores inside VECS.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. If the system prompts you, enter the credentials of your vCenter.
5. Explore the certificates stored inside the VMware Endpoint Certificate Store (VECS).

   VMware Endpoint Certificate Store explains what is in the individual stores.
6. To view details for a certificate, select the appropriate certificate tab, select the certificate, and expand the certificate to view details.

Set the Threshold for vCenter Certificate Expiration Warnings Using the vSphere Client

vCenter monitors all certificates in the VMware Endpoint Certificate Store (VECS) and issues an alarm when a certificate is 30 days or less from its expiration. You can use the vSphere Client to change how soon you are warned with the vpxd.cert.threshold advanced option.

1. Log in to the vSphere Client.
2. Select the vCenter object and click **Configure**.
3. Click **Advanced Settings**.
4. Click **Edit Settings** and filter for `threshold`.
5. Change the setting of vpxd.cert.threshold to the desired value and click **Save**.

Renew VMCA Certificates with New VMCA-Signed Certificates Using the vSphere Client

You can replace all VMCA-signed certificates with new VMCA-signed certificates. This process is called renewing certificates. You can renew selected certificates or all certificates in your environment from the vSphere Client.

For certificate management, you have to supply the password of the administrator of the local domain (administrator@vsphere.local by default). If you are renewing certificates for a vCenter system, you also have to supply the vCenter Single Sign-On credentials for a user with administrator privileges on the vCenter system.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.

3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. If the system prompts you, enter the credentials of your vCenter.
5. Renew the VMCA-signed machine SSL certificate for the local system.
   a) From the **Machine SSL** tab, select the desired certificate and click **Renew**.
   b) Specify the duration of the certificate in days.
   c) Click the checkbox to acknowledge that you have backed up vCenter and its databases.
   d) Click **Renew**.
      The system renews the certificate and displays a success message.
   e) When the certificate has been changed message appears, click **Refresh** to refresh your browser.

Replace Certificates with Custom Certificates Using the vSphere Client

You can use the vSphere Client to replace the default certificates with custom certificates.

You can use the vSphere Client to generate CSRs for each machine, and replace certificates when you receive them from your internal or third-party Certificate Authority (CA). When you submit the CSRs to your internal or third-party CA, the CA returns signed certificates and the root certificate. You can upload both the root certificate and the signed certificates from the vSphere Client.

Generate Certificate Signing Request for Machine SSL Certificate Using the vSphere Client (Custom Certificates)

The machine SSL certificate is used by the reverse proxy service on every vCenter node. Each machine must have a machine SSL certificate for secure communication with other services. You can use the vSphere Client to generate a Certificate Signing Request (CSR) for the machine SSL certificate and to replace the certificate once it is ready.

The certificate must meet the following requirements:

- Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded). The vSphere Client and API still accept a key size up to 16384 bits when generating the Certificate Signing Request.
- CRT format
- x509 version 3
- SubjectAltName must contain DNS Name=<machine_FQDN>.
- Contains the following Key Usages: Digital Signature, Key Encipherment

Note:
vSphere's FIPS certificate only validates RSA key sizes of 2048 bits and 3072 bits.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.
   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. Enter the credentials of your vCenter.
5. Generate the CSR.
   a) Under the **Machine SSL** tab, select the desired certificate and click **Generate Certificate Signing Request (CSR)**.
   b) Enter your certificate information and click **Next**.
      2048 (bits) is the default value for the key size. Change this value as required.

Note:
When you use vCenter to generate a CSR with a large key size, the generation takes a few minutes to complete because of the CPU-intensive nature of the operation.

c) Copy or download the CSR.
d) Click **Finish**.
e) Provide the CSR to your Certificate Authority.

When the Certificate Authority returns the certificate, replace the existing certificate in the certificate store. See Add Custom Certificates Using the vSphere Client.

Add a Trusted Root Certificate to the Certificate Store Using the vSphere Client

If you want to use third-party certificates in your environment, you must add a trusted root certificate to the certificate store. You can do so using the vSphere Client.

Obtain the custom root certificate from your third-party or in-house certificate authority (CA).

vSphere accepts only valid CA certificates for import. To be valid, a CA certificate must have the CA bit and the keyCertSign bit set in the basic constraint and the key usage X.509 v3 certificate extensions respectively. This implies that the certificate is a CA and its purpose is for certificate signing. See https://www.rfc-editor.org/rfc/rfc5280 for more information.

Ensure that the keyCertSign bit is set for all the certificates in the chain.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.
   If you specified a different domain during installation, log in as administrator@`mydomain`.
3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. If the system prompts you, enter the credentials of your vCenter.
5. Under the **Trusted Root** tab, click **Add Trusted Root Certificate**.
6. Click **Browse** and select the location of the certificate chain.
   You can use a file of type CER, PEM, or CRT.
7. Click **Add**.
   The certificate is added to the store.

   Note:
   In vSphere 8.0 Update 2 and later, the **Start Root certificate push to vCenter Hosts** check box is removed. vCenter pushes the root certificates to all connected hosts in the inventory when a certificate is added. When a host with different root certificates from vCenter is connected, vCenter pushes the root certificates to correct this difference. In this case, vCenter root certificates overwrite the ones on the host, so administrators can ensure that any custom root certificates needed throughout the inventory are added to vCenter.

Add Custom Certificates Using the vSphere Client

You can use the vSphere Client to add custom Machine SSL certificates to the certificate store.

Generate certificate signing requests (CSRs) for each certificate that you want to replace. See Generate Certificate Signing Request for Machine SSL Certificate Using the vSphere Client (Custom Certificates). Place the certificate and private key in a location that the vCenter can access.

Usually, replacing the machine SSL certificate for each component is sufficient.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.
   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. If the system prompts you, enter the credentials of your vCenter.
5. Under the **Machine SSL** tab, select the certificate then click **Import and Replace Certificate**.
6. Click the appropriate certificate replacement option and click **Next**.

Option	Description
Replace with VMCA certificate	Creates a VMCA-generated CSR to replace the current certificate.
Replace with external CA certificate where CSR is generated from vCenter (private key embedded)	Use a certificate signed using a vCenter generated CSR to replace the current certificate.
Replace with external CA certificate (requires private key)	Use a certificate signed by an external CA to replace the current certificate.

7. Enter the CSR information, or upload the appropriate certificates.
8. Click the checkbox to acknowledge that you have backed up vCenter and its databases.
9. Review the information and click **Finish**.
   The system replaces the certificate and displays a success message.
10. When the certificate has been changed message appears, click **Refresh** to refresh your browser.

Generate a VMCA Leaf Certificate

You can generate a leaf certificate that is signed by the VMware Certificate Authority (VMCA) for use in your VMware infrastructure.

Generate a Certificate Signing Request (CSR) on the host in your VMware infrastructure where you want to install the leaf certificate.

In addition to VMware Certificate Authority (VMCA) handling all certificate management, it can generate leaf certificates. Leaf certificates are signed by VMCA and are used to identify other VMware resources. VMCA-generated leaf certificates are not stored in VECS. Also, vCenter does not track these leaf certificates for expiration.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.
   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. If the system prompts you, enter the credentials of your vCenter.
5. Under the **Trusted Root** tab, select the VMCA root certificate and click **Issue New Leaf Certificate**.
6. Browse for the CSR that you previously generated, specify a duration, then click **Next**.
7. Click **Download Certificates** to save the Leaf and Root certificates.

The generated Leaf and Root certificates are created and downloaded to the specified location.

Import the Leaf and Root certificates to the target host in your VMware infrastructure.

Managing Certificates Using the vSphere Certificate Manager Utility

The vSphere Certificate Manager utility allows you to perform most certificate management tasks interactively from the command line. vSphere Certificate Manager prompts you for the task to perform, for certificate locations and other information as needed, and then stops and starts services and replaces certificates for you.

To understand more about options for replacing the default certificates, see Replacing vSphere Certificates.

> **Note:**
> If you use the VMCA as an intermediate CA, or use custom certificates, you might encounter significant complexity and the potential for a negative impact to your security, and an unnecessary increase in your operational risk. For more information about managing certificates within a vSphere environment, see the blog post titled *New Product Walkthrough - Hybrid vSphere SSL Certificate Replacement* at http://vmware.com/go/hybridvmca.

If you use vSphere Certificate Manager, you are not responsible for placing the certificates in VECS (VMware Endpoint Certificate Store) and you are not responsible for starting and stopping services.

You run vSphere Certificate Manager options in sequence to complete a workflow. Several options, for example, generating CSRs, are used in different workflows. Before you run vSphere Certificate Manager, be sure that you understand the replacement process and procure the certificates that you want to use.

> **CAUTION:**
> vSphere Certificate Manager supports one level of revert. If you run vSphere Certificate Manager twice and notice that you unintentionally corrupted your environment, the tool cannot revert the first of the two runs.

vSphere Certificate Manager Utility Location

The vSphere Certificate Manager utility is located at:

```
/usr/lib/vmware-vmca/bin/certificate-manager
```

> **Note:**
>
> When running vSphere Certificate Manager, some options prompt you as follows:
>
> ```
> Enter proper value for VMCA 'Name':
> ```
>
> Respond to this prompt by entering the fully qualified domain name of the machine on which the certificate configuration is running.

Workflows in the vSphere Certificate Manager Utility

The following table presents an overview of the certificate replacement workflows you can accomplish by using the vSphere Certificate Manager utility.

Table 84: Workflows in the vSphere Certificate Management Utility

Workflow	Description	See
Replacing VMCA root certificate with custom signing certificate and replacing all certificates	To generate the VMCA root certificate, and replace all certificates, use Option 4, Regenerate a new VMCA Root certificate and replace all Certificates.	Regenerate a New VMCA Root Certificate and Replace All Certificates Using the Certificate Manager
Making VMCA an intermediate certificate authority	To make VMCA an intermediate CA, you must run the vSphere Certificate Manager utility several times and use multiple options. This workflow gives the complete set of steps for replacing both machine SSL certificates and solution user certificates.	Make VMCA an Intermediate Certificate Authority Using the Certificate Manager

Workflow	Description	See
Replacing all certificates with custom certificates	To replace all certificates with custom certificates, you must run the vSphere Certificate Manager utility several times and use multiple options. This workflow gives the complete set of steps for replacing both machine SSL certificates and solution user certificates.	Replace All Certificates with a Custom Certificate Using the Certificate Manager
Reverting the last performed operation	To revert the last performed certificate operation and return to the previous state, use Option 7, Revert last performed operation by re-publishing old certificates.	Revert Last Performed Operation by Republishing Old Certificates Using the Certificate Manager
Resetting all certificates	To replace all existing vCenter certificates with certificates that are signed by VMCA, use Option 8, Reset all Certificates.	Reset All Certificates Using the Certificate Manager

Regenerate a New VMCA Root Certificate and Replace All Certificates Using the Certificate Manager

You can use the vSphere Certificate Manager utility to regenerate the VMCA root certificate, and replace the local machine SSL certificate and the local solution user certificates with VMCA-signed certificates. When multiple vCenter instances are connected in Enhanced Linked Mode configuration, you must replace certificates on each vCenter.

You must know the following information when you run vSphere Certificate Manager with this option.

- Password for administrator@vsphere.local.
- The FQDN of the machine for which you want to generate a new VMCA-signed certificate. All other properties default to the predefined values but can be changed.

When you replace the existing machine SSL certificate with a new VMCA-signed certificate, vSphere Certificate Manager prompts you for information and enters all values, except for the password and the IP address of the vCenter, into the `certool.cfg` file.

- Password for administrator@vsphere.local
- Two-letter country code
- Company name
- Organization name
- Organization unit
- State
- Locality
- IP address (optional)
- Email (optional)
- Host name, that is, the fully qualified domain name of the machine for which you want to replace the certificate. If the host name does not match the FQDN, certificate replacement does not complete correctly and your environment might end up in an unstable state.
- IP address of vCenter
- VMCA name, that is, the fully qualified domain name of the machine on which the certificate configuration is running.
- OU (organizationalUnitName) (optional)

1. Log in to the vCenter shell and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```

2. Select option 4, Regenerate a new VMCA Root Certificate and replace all certificates.
3. Enter the administrator user and password.
4. Respond to the prompts.

   vSphere Certificate Manager generates a new VMCA root certificate based on your input and replaces all certificates on the system where you are running vSphere Certificate Manager. The replacement process is complete after vSphere Certificate Manager has restarted the services.
5. To replace the machine SSL certificate, run vSphere Certificate Manager with option 3, Replace Machine SSL certificate with VMCA Certificate.
6. To replace the solution user certificates, run Certificate Manager with option 6, Replace Solution user certificates with VMCA certificates.

Make VMCA an Intermediate Certificate Authority Using the Certificate Manager

You can use the vSphere Certificate Manager utility to make VMCA an Intermediate CA. After you complete the process, VMCA signs all new certificates with the full chain. If you want, you can use vSphere Certificate Manager to replace all existing certificates with new VMCA-signed certificates.

To make VMCA an intermediate CA, you must run vSphere Certificate Manager several times. The high-level steps for replacing both machine SSL certificates and solution user certificates include:

1. Launching the vSphere Certificate Manager utility.
2. Generating a CSR by running Option 2, Replace VMCA Root certificate with Custom Signing Certificate and replace all Certificates. You might have to provide some information about the certificate next. When prompted for an option again, select Option 1, Generate Certificate Signing Request(s) and Key(s) for VMCA Root Signing certificate.
3. Submitting the CSR to your external or enterprise CA. You receive a signed certificate and a root certificate from the CA.
4. Combining the VMCA root certificate with the CA root certificate and saving the file.
5. Replacing certificates by running Option 2, Replace VMCA Root certificate with Custom Signing Certificate and replace all Certificates, and following the prompts. This process replaces all certificates on the local machine.
6. (Optional) Replacing certificates on each node when multiple vCenter instances are connected in Enhanced Linked Mode configuration by:
   a. First replacing the machine SSL certificate with the (new) VMCA certificate (Option 3, Replace Machine SSL certificate with VMCA Certificate).
   b. Then replacing the solution user certificates with the (new) VMCA certificate (Option 6, Replace Solution user certificates with VMCA certificates).

Generate CSR Using the Certificate Manager and Prepare Root Certificate (Intermediate CA)

You can use the vSphere Certificate Manager utility to generate Certificate Signing Requests (CSRs). Submit those CSRs to your enterprise CA or to an external certificate authority for signing. You can use the signed certificates with the different supported certificate replacement processes.

vSphere Certificate Manager prompts you for information. The prompts depend on your environment and on the type of certificate that you want to replace.

For any CSR generation, you are prompted for the password of the administrator@vsphere.local user, or for the administrator of the vCenter Single Sign-On domain that you are connecting to.

- You can use vSphere Certificate Manager to create the CSR.

  Note:
  In vSphere 8.0 and later, if you use the vSphere Certificate Manager to generate the CSR, the minimum key size is changed to 3072 bits from 2048. In vSphere 8.0 Update 1 and later, use the vSphere Client to generate a CSR with a key size of 2048 bits.

  Note:
  vSphere's FIPS certificate only validates RSA key sizes of 2048 bits and 3072 bits.

- If you prefer to create the CSR manually, the certificate that you send to be signed must meet the following requirements.
  - Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded)
  - PEM format. VMware supports PKCS8 and PKCS1 (RSA keys). When keys are added to VECS, they are converted to PKCS8.
  - x509 version 3
  - The CA extension must be set to true for root certificates, and cert sign must be in the list of requirements. For example:

    ```
    basicConstraints        = critical,CA:true
    keyUsage                = critical,digitalSignature,keyCertSign
    ```
  - CRL signing must be enabled.
  - Extended Key Usage can be either empty or contain Server Authentication.
  - No explicit limit to the length of the certificate chain. VMCA uses the OpenSSL default, which is 10 certificates.
  - Certificates with wildcards or with more than one DNS name are not supported.
  - You cannot create subsidiary CAs of VMCA.

    See the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2112009, Creating a Microsoft Certificate Authority Template for SSL certificate creation in vSphere 6.x, for an example using Microsoft Certificate Authority.

1. Log in to the vCenter shell and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```
2. Select Option 2, Replace VMCA Root certificate with Custom Signing Certificate and replace all Certificates.

   Initially, you use this option to generate the CSR, not to replace certificates.
3. Enter the administrator user and password.
4. Select Option 1, Generate Certificate Signing Request(s) and Key(s) for VMCA Root Signing certificate, to generate the CSR and answer the prompts.

   As part of the process, you have to provide a directory. vSphere Certificate Manager places the certificate to be signed (`*.csr` file) and the corresponding key file (`*.key` file) in the directory.
5. Name the certificate signing request (CSR) `root_signing_cert.csr`.
6. Send the CSR to your enterprise or external CA for signing and name the resulting signed certificate `root_signing_cert.cer`.
7. In a text editor, combine the certificates as follows.

   ```
   -----BEGIN CERTIFICATE-----
   Signed VMCA root certificate
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   CA intermediate certificates
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   Root certificate of enterprise or external CA
   -----END CERTIFICATE-----
   ```
8. Save the file as `root_signing_chain.cer`.

Replace the existing root certificate with the chained root certificate. See Replace VMCA Root Certificate with Custom Signing Certificate and Replace All Certificates Using the Certificate Manager.

Replace VMCA Root Certificate with Custom Signing Certificate and Replace All Certificates Using the Certificate Manager

You can use the vSphere Certificate Manager utility to generate a CSR and send the CSR to an enterprise or third-party CA for signing. You can then replace the VMCA root certificate with a custom signing certificate and replace all existing certificates with certificates that are signed by the custom CA.

- Generate the certificate chain.
  - You can use vSphere Certificate Manager to create the CSR or create the CSR manually.
  - After you receive the signed certificate from your third-party or enterprise CA, combine it with the initial VMCA root certificate to create the full chain.

    See Generate CSR Using the Certificate Manager and Prepare Root Certificate (Intermediate CA) for certificate requirements and the process of combining the certificates.
- Gather the information that you need.
  - Password for administrator@vsphere.local
  - Valid custom certificate for Root (`.crt` file)
  - Valid custom key for Root (`.key` file)

You run vSphere Certificate Manager on vCenter to replace the VMCA root certificate with a custom signing certificate.

1. Log in to the vCenter shell and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```
2. Select Option 2, Replace VMCA Root certificate with Custom Signing Certificate and replace all Certificates.
3. Enter the administrator user and password.
4. Select Option 2, Import custom certificate(s) and key(s) to replace existing VMCA Root Signing certificate, and respond to the prompts.
   a) Specify the full path to the root certificate when prompted.
   b) If you are replacing certificates for the first time, you are prompted for information to be used for the machine SSL certificate.

      This information includes the required FQDN of the machine and is stored in the `certool.cfg` file.

Replace Machine SSL Certificate with VMCA Certificate (Intermediate CA) Using the Certificate Manager

When you use VMCA as an intermediate CA, you can replace the machine SSL certificate explicitly using the vSphere Certificate Manager utility. First you replace the VMCA root certificate on the vCenter, then you can replace the machine SSL certificate, which will be signed by the new root of the VMCA. You can also use this option to replace machine SSL certificates that are corrupt or about to expire.

- You must know the following information to run vSphere Certificate Manager with this option.
  - Password for administrator@vsphere.local.
  - The FQDN of the machine for which you want to generate a new VMCA-signed certificate. All other properties default to the predefined values but can be changed.
  - Host name or IP address of the vCenter system.

When you replace the existing machine SSL certificate with a new VMCA-signed certificate, vSphere Certificate Manager prompts you for information and enters all values, except for the password and the IP address of the vCenter, into the `certool.cfg` file.

- Password for administrator@vsphere.local
- Two-letter country code
- Company name
- Organization name
- Organization unit
- State
- Locality
- IP address (optional)
- Email
- Host name, that is, the fully qualified domain name of the machine for which you want to replace the certificate. If the host name does not match the FQDN, certificate replacement does not complete correctly and your environment might end up in an unstable state.
- IP address of vCenter

- VMCA name, that is, the fully qualified domain name of the machine on which the certificate configuration is running.

  Note:
  The OU (organizationalUnitName) field is no longer mandatory.

1. Log in to the vCenter shell and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```

2. Select Option 3, Replace Machine SSL certificate with VMCA Certificate.
3. Enter the administrator user and password.
4. Respond to the prompts.

   vSphere Certificate Manager stores the information in the `certool.cfg` file.

vSphere Certificate Manager replaces the machine SSL certificate.

Replace Solution User Certificates with VMCA Certificates (Intermediate CA) Using the Certificate Manager

When you use VMCA as an intermediate CA, you can replace the solution user certificate explicitly using the vSphere Certificate Manager utility. First you replace the VMCA root certificate on the vCenter, then you can replace the solution user certificate, which is signed by the new root of the VMCA. You can also use this option to replace solution certificates that are corrupt or about to expire.

- Restart all vCenter nodes explicitly if you replaced the VMCA root certificate in a deployment consisting of multiple instances of vCenter in Enhanced Linked Mode configuration.
- You must know the following information to run vSphere Certificate Manager with this option.
  - Password for administrator@vsphere.local
  - Host name or IP address of the vCenter system

1. Log in to the vCenter shell and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```

2. Select option 6, Replace Solution user certificates with VMCA certificates.
3. Enter the administrator user and password.
4. Respond to the prompts.

   See the Broadcom knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2112281 for more information.

vSphere Certificate Manager replaces all solution user certificates.

Replace All Certificates with a Custom Certificate Using the Certificate Manager

You can use the vSphere Certificate Manager utility to replace all certificates with custom certificates. Before you start the process, you must send CSRs to your certificate authority (CA). You can use Certificate Manager to generate the CSRs.

One option is to replace only the machine SSL certificate, and to use the solution user certificates that are provisioned by VMCA. Solution user certificates are used only for communication between vSphere components.

When you use custom certificates, you replace the VMCA-signed certificates with custom certificates. You can use the vSphere Client, the vSphere Certificate Manager utility, or CLIs for manual certificate replacement. Certificates are stored in VECS.

To replace all certificates with custom certificates, you must run the vSphere Certificate Manager utility several times. The high-level steps for replacing both machine SSL certificates and solution user certificates include:

1. Launching the vSphere Certificate Manager utility.
2. Generating certificate signing requests for the machine SSL certificate and the solution user certificates separately on each machine.

a. To generate CSRs for the machine SSL certificate, select Option 1, Replace Machine SSL certificate with Custom Certificate. When prompted for an option again, select Option 1, Generate Certificate Signing Request(s) and Key(s) for Machine SSL certificate.
b. If company policy does not allow a hybrid deployment, select Option 5, Replace Solution user certificates with Custom Certificate.

3. Submitting the CSR to your external or enterprise CA. You receive a signed certificate and a root certificate from the CA.
4. After receiving the signed certificates and the root certificate from your CA, replacing the machine SSL certificate on each machine by using Option 1, Replace Machine SSL certificate with Custom Certificate.
5. If you also want to replace the solution user certificates, select Option 5, Replace Solution user certificates with Custom Certificate.
6. Finally, when multiple vCenter instances are connected in Enhanced Linked Mode configuration, repeating the process on each node.

Generate Certificate Signing Requests Using the Certificate Manager (Custom Certificates)

You can use the vSphere Certificate Manager utility to generate Certificate Signing Requests (CSRs) that you can then use with your enterprise CA or send to an external certificate authority. You can use the certificates with the different supported certificate replacement processes.

vSphere Certificate Manager prompts you for information. The prompts depend on your environment and on the type of certificate you want to replace.

- For any CSR generation, you are prompted for the password of the administrator@vsphere.local user, or for the administrator of the vCenter Single Sign-On domain that you are connecting to.
- You are prompted for the host name or IP address of the vCenter.
- To generate a CSR for a machine SSL certificate, you are prompted for certificate properties, which are stored in the `certool.cfg` file. For most fields, you can accept the default or provide site-specific values. The FQDN of the machine is required.

  Note:
  In vSphere 8.0 and later, if you use the vSphere Certificate Manager to generate the CSR, the minimum key size is changed to 3072 bits from 2048. In vSphere 8.0 Update 1 and later, use the vSphere Client to generate a CSR with a key size of 2048 bits.

  Note:
  vSphere's FIPS certificate only validates RSA key sizes of 2048 bits and 3072 bits.

1. Log in to each vCenter (the vCenter shell) in your environment and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```

2. Selection Option 1, Replace Machine SSL certificate with Custom Certificate.
3. Enter the administrator user and password.
4. Select Option 1, Generate Certificate Signing Request(s) and Key(s) for Machine SSL certificate, to generate the CSR, answer the prompts and exit vSphere Certificate Manager.

   As part of the process, you have to provide a directory. vSphere Certificate Manager places the certificate and key files in the directory.
5. If you also want to replace all solution user certificates, restart vSphere Certificate Manager and selection Option 5, Replace Solution user certificates with Custom Certificate.
6. Supply the password and the vCenter IP address or host name if prompted.
7. Select Option 1, Generate Certificate Signing Request(s) and Key(s) for Solution User Certificates, to generate the CSRs, answer the prompts and exit vSphere Certificate Manager.

   As part of the process, you have to provide a directory. Certificate Manager places the certificate and key files in the directory.

To perform certificate replacement, see Replace Machine SSL Certificate with Custom Certificate Using the Certificate Manager.

Replace Machine SSL Certificate with Custom Certificate Using the Certificate Manager

You can use the vSphere Certificate Manager utility to replace the machine SSL certificate on each node with a custom certificate. The machine SSL certificate is used by the reverse proxy service on every vCenter node. Each machine must have a machine SSL certificate for secure communication with other services.

Before you start, you need a CSR for each machine in your environment. You can generate the CSR using vSphere Certificate Manager or explicitly.

1. To generate the CSR using vSphere Certificate Manager, see Generate Certificate Signing Requests Using the Certificate Manager (Custom Certificates).
2. To generate the CSR explicitly, request a certificate for each machine from your third-party or enterprise CA. The certificate must meet the following requirements:
   – Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded)
   – CRT format
   – x509 version 3
   – SubjectAltName must contain DNS Name=<machine_FQDN>.
   – Contains the following Key Usages: Digital Signature, Key Encipherment

See the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2112014, Obtaining vSphere certificates from a Microsoft Certificate Authority.

1. Log in to vCenter and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```

2. Selection Option 1, Replace Machine SSL certificate with Custom Certificate.
3. Enter the administrator user and password.
4. Select Option 2, Import custom certificate(s) and key(s) to replace existing Machine SSL certificate, to start certificate replacement and respond to the prompts.

   vSphere Certificate Manager prompts you for the following information:

   - Password for administrator@vsphere.local
   - Valid Machine SSL custom certificate (`.crt` file)
   - Valid Machine SSL custom key (`.key` file)
   - Valid signing certificate for the custom machine SSL certificate (`.crt` file)
   - IP address of the vCenter

Replace Solution User Certificates with Custom Certificates Using the Certificate Manager

Many companies only require that you replace certificates of services that are accessible externally. However, the vSphere Certificate Manager utility also supports replacing solution user certificates. Solution users are collections of services, for example, all services that are associated with the vSphere Client.

Before you start, you need a CSR for each machine in your environment. You can generate the CSR using vSphere Certificate Manager or explicitly.

1. To generate the CSR using vSphere Certificate Manager, see Generate Certificate Signing Requests Using the Certificate Manager (Custom Certificates).
2. Request a certificate for each solution user on each node from your third-party or enterprise CA. You can generate the CSR using vSphere Certificate Manager or prepare it yourself. The CSR must meet the following requirements:
   – Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded)
   – CRT format
   – x509 version 3
   – SubjectAltName must contain DNS Name=<machine_FQDN>.
   – Each solution user certificate must have a different `Subject`. Consider, for example, including the solution user name (such as vpxd) or other unique identifier.
   – Contains the following Key Usages: Digital Signature, Key Encipherment

See also the Broadcom knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2112014, Obtaining vSphere certificates from a Microsoft Certificate Authority.

When you are prompted for a solution user certificate, provide the complete signing certificate chain of the third-party CA.

The format looks similar to the following.

```
-----BEGIN CERTIFICATE-----
Signing certificate
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
CA intermediate certificates
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
Root certificate of enterprise or external CA
-----END CERTIFICATE-----
```

1. Log in to vCenter and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```

2. Select Option 5, Replace Solution user certificates with Custom Certificate.
3. Enter the SSO user and password.
4. Select Option 2, Import custom certificate(s) and key(s) to replace existing Solution User Certificates, and respond to the prompts.

   vSphere Certificate Manager prompts you for the following information:

   - Password for administrator@vsphere.local
   - Certificate and key for machine solution user
   - The certificate and key (`vpxd.crt` and `vpxd.key`) for the machine solution user
   - The full set of certificates and keys (`vpxd.crt` and `vpxd.key`) for all solution users

Revert Last Performed Operation by Republishing Old Certificates Using the Certificate Manager

When you perform a certificate management operation by using the vSphere Certificate Manager utility, the current certificate state is stored in the BACKUP_STORE store in VECS before certificates are replaced. You can revert the last performed operation and return to the previous state.

> **Note:**
> The revert operation restores what is currently in the BACKUP_STORE. If you run vSphere Certificate Manager with two different options and you then attempt to revert, only the last operation is reverted.

1. Log in to the vCenter shell and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```

2. Select Option 7, Revert last performed operation by re-publishing old certificates.
3. Enter the administrator user and password.
4. To continue, enter `Y`.

Reset All Certificates Using the Certificate Manager

You can use the vSphere Certificate Manager utility to replace all existing vCenter certificates with certificates that are signed by VMCA.

When you use this option, you overwrite all custom certificates that are currently in VMware Endpoint Certificate Store (VECS).
vSphere Certificate Manager can replace all certificates. Which certificates are replaced depends on which options you select.

1. Log in to vCenter shell and start the vSphere Certificate Manager.

   ```
   /usr/lib/vmware-vmca/bin/certificate-manager
   ```

2. Select Option 8, Reset all Certificates.
3. Enter the administrator user and password.
4. When prompted, enter your certificate information.

After certificates are replaced and services are restarted, verify your certificate information.

Manual vSphere Certificate Replacement

For some special certificate replacement cases, you cannot use the vSphere Certificate Manager utility. Instead, you can use the CLIs included with your installation for certificate replacement.

Guidelines for Stopping and Starting of vCenter Services

For certain parts of manual certificate replacement, you must stop all vCenter services and then start only the services that manage the certificate infrastructure. If you stop services only when needed, you can minimize downtime.

You have to stop and start services as part of the certificate replacement process. You can use the `service-control` command for starting and stopping services. You can start and stop all services or individual services. See the command-line help for more information.

Follow these guidelines.

- Do not stop services to generate new public/private key pairs or new certificates.
- If you are the only administrator, you do not have to stop services when you add a new root certificate. The old root certificate remains available, and all services can still authenticate with that certificate.
- Stop services right before you delete a machine SSL certificate in VMware Endpoint Certificate Store (VECS).

Replace Existing VMCA-Signed Certificates with New VMCA-Signed Certificates Using the CLI

If the VMware Certificate Authority (VMCA) root certificate expires in the near future, or if you want to replace it for other reasons, you can use the CLI to generate a new root certificate and add it to the VMware Directory Service. You can then generate new machine SSL certificates and solution user certificates using the new root certificate. Starting with VCF 9.1, the VMCA and solution certificates that are due to expire within two years are automatically renewed, and replaced when you upgrade your vCenter to major or minor version. A new VMCA root certificate is provisioned if the expiry threshold is met.

Only administrator@vsphere.local or other users in the CAAdmins group can perform certificate management tasks. See Add Members to a vCenter Single Sign-On Group.

Use the vSphere Certificate Manager utility to replace certificates for most cases.

If you need fine-grained control, this scenario gives detailed step-by-step instructions for replacing the complete set of certificates using CLI commands. You can instead replace only individual certificates using the procedure in the corresponding task.

Generate a New VMCA-Signed Root Certificate Using the CLI

You can generate new VMCA-signed certificates with the `certool` CLI and publish the certificates to vmdir.

1. On the vCenter, generate a new self-signed certificate and private key.

   ```
   certool --genselfcacert --outprivkey <key_file_path> --outcert <cert_file_path> --config <config_file>
   ```

2. Replace the existing root certificate with the new certificate.

   ```
   certool --rootca --cert <cert_file_path> --privkey <key_file_path>
   ```

   The command generates the certificate, adds it to vmdir, and adds it to VECS.

3. Stop all services and start the services that handle certificate creation, propagation, and storage.

   ```
   service-control --stop --all
   ```

```
service-control --start vmafdd
service-control --start vmdird
service-control --start vmcad
```

4. Optional: Publish the new root certificate to vmdir.

   ```
   dir-cli trustedcert publish --cert newRoot.crt
   ```

   The command updates all instances of vmdir immediately. If you do not run the command, propagation of the new certificate to all nodes might take a while.

5. Restart all services.

   ```
   service-control --start --all
   ```

Generate a New VMCA-Signed Root Certificate

The following example shows all the steps for verifying the current root CA information, and for regenerating the root certificate.

1. (Optional) On the vCenter, list the VMCA root certificate to make sure it is in the certificate store.

   ```
   /usr/lib/vmware-vmca/bin/certool --getrootca
   ```

   The output looks similar to this:

   ```
   output:
   Certificate:
       Data:
           Version: 3 (0x2)
           Serial Number:
               cf:2d:ff:49:88:50:e5:af
       ...
   ```

2. (Optional) List the VECS TRUSTED_ROOTS store and compare the certificate serial number there with the output from Step 1.

   ```
   /usr/lib/vmware-vmafd/bin/vecs-cli entry list --store TRUSTED_ROOTS --text
   ```

   In the simplest case with only one root certificate, the output looks like this:

   ```
   Number of entries in store :    1
   Alias : 960d43f31eb95211ba3a2487ac840645a02894bd
   Entry type :    Trusted Cert
   Certificate:
       Data:
           Version: 3 (0x2)
           Serial Number:
               cf:2d:ff:49:88:50:e5:af
   ```

3. Generate a new VMCA root certificate. The command adds the certificate to the TRUSTED_ROOTS store in VECS and in vmdir (VMware Directory Service).

   ```
   /usr/lib/vmware-vmca/bin/certool --selfca --config=/usr/lib/vmware-vmca/share/config/
   certool.cfg
   ```

Replace Machine SSL Certificates with VMCA-Signed Certificates Using the CLI

After you generate a new VMCA-signed root certificate, you can use the `vecs-cli` command to replace all machine SSL certificates in your environment.

Be prepared to stop all services and to start the services that handle certificate propagation and storage.

Each machine must have a machine SSL certificate for secure communication with other services. When multiple vCenter instances are connected in Enhanced Linked Mode configuration, you must run the Machine SSL certificate generation commands on each node.

1. Make one copy of `certool.cfg` for each machine that needs a new certificate.

   You can find the `certool.cfg` file in the `/usr/lib/vmware-vmca/share/config/` directory.

2. Edit the custom configuration file for each machine to include that machine's FQDN.

   Run `NSLookup` against the machine's IP address to see the DNS listing of the name, and use that name for the Hostname field in the file.

3. Generate a public/private key file pair and a certificate for each file, passing in the configuration file that you just customized.

   For example:

   ```
   certool --genkey --privkey=machine1.priv --pubkey=machine1.pub
   certool --gencert --privkey=machine1.priv --cert machine1.crt --Name=Machine1_Cert --config machine1.cfg
   ```

4. Stop all services and start the services that handle certificate creation, propagation, and storage.

   ```
   service-control --stop --all
   service-control --start vmafdd
   service-control --start vmdird
   service-control --start vmcad
   ```

5. Add the new certificate to VECS.

   All machines need the new certificate in the local certificate store to communicate over SSL. You first delete the existing entry, then add the new entry.

   ```
   vecs-cli entry delete --store MACHINE_SSL_CERT --alias __MACHINE_CERT
   vecs-cli entry create --store MACHINE_SSL_CERT --alias __MACHINE_CERT --cert machine1.crt --key
    machine1.priv
   ```

6. Restart all services.

   ```
   service-control --start --all
   ```

Replacing Machine Certificates with VMCA-Signed Certificates

1. Create a configuration file for the SSL certificate and save it as `ssl-config.cfg` in the current directory.

   ```
   Country = US
   Name = vmca-<FQDN-example>
   Organization = <my_company>
   OrgUnit = <my_company Engineering>
   State = <my_state>
   Locality = <mytown>
   Hostname = <FQDN>
   ```

2. Generate a key pair for the machine SSL certificate. In a deployment of multiple vCenter instances connected in Enhanced Linked Mode configuration, run this command on each vCenter node.

   ```
   /usr/lib/vmware-vmca/bin/certool --genkey --privkey=ssl-key.priv --pubkey=ssl-key.pub
   ```

   The `ssl-key.priv` and `ssl-key.pub` files are created in the current directory.

3. Generate the new machine SSL certificate. This certificate is signed by VMCA. If you replaced the VMCA root certificate with custom certificate, VMCA signs all certificates with the full chain.

   ```
   /usr/lib/vmware-vmca/bin/certool --gencert --cert=new-vmca-ssl.crt --privkey=ssl-key.priv --
   config=ssl-config.cfg
   ```

   The `new-vmca-ssl.crt` file is created in the current directory.

4. (Optional) List the content of VECS.

   ```
   /usr/lib/vmware-vmafd/bin/vecs-cli store list
   ```

   – Sample output on vCenter:

   ```
   output (on vCenter):
   MACHINE_SSL_CERT
   TRUSTED_ROOTS
   TRUSTED_ROOT_CRLS
   machine
   vsphere-webclient
   vpxd
   vpxd-extension
   hvc
   ```

```
data-encipherment
APPLMGMT_PASSWORD
SMS
wcp
KMS_ENCRYPTION
```

5. Replace the Machine SSL certificate in VECS with the new Machine SSL certificate. The `--store` and `--alias` values have to exactly match with the default names.
   – On each vCenter, run the following commands to update the Machine SSL certificate in the MACHINE_SSL_CERT store. You must update the certificate for each machine separately because each has a different FQDN.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store MACHINE_SSL_CERT --alias
 __MACHINE_CERT
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store MACHINE_SSL_CERT --alias
 __MACHINE_CERT --cert new-vmca-ssl.crt --key ssl-key.priv
```

You can also replace the certificates for your ESX hosts. See the *vSphere Security* publication.

Replace Solution User Certificates with New VMCA-Signed Certificates Using the CLI

After you replace the machine SSL certificates, you can use the `dir-cli` command to replace all solution user certificates. Solution user certificates must be valid, that is, not expired, but none of the other information in the certificate is used by the certificate infrastructure.

Be prepared to stop all services and to start the services that handle certificate propagation and storage.

Many VMware customers do not replace solution user certificates. They replace only the machine SSL certificates with custom certificates. This hybrid approach satisfies the requirements of their security teams.

- Certificates either sit behind a proxy, or they are custom certificates.
- No intermediate CAs are used.

You replace the machine solution user certificate and the solution user certificate on each vCenter system.

> **Note:**
> When you list solution user certificates in large deployments, the output of `/usr/lib/vmware-vmafd/bin/dir-cli list` includes all solution users from all nodes. Run `/usr/lib/vmware-vmafd/bin/vmafd-cli get-machine-id --server-name localhost` to find the local machine ID for each host. Each solution user name includes the machine ID.

1. Make one copy of `certool.cfg`, remove the Name, IP address, DNS name, and email fields, and rename the file, for example, to `sol_usr.cfg`.

   You can name the certificates from the command line as part of generation. The other information is not needed for solution users. If you leave the default information, the certificates that are generated are potentially confusing.

2. Generate a public/private key file pair and a certificate for each solution user, passing in the configuration file that you just customized.

   For example:

```
/usr/lib/vmware-vmca/bin/certool --genkey --privkey=vpxd.priv --pubkey=vpxd.pub
/usr/lib/vmware-vmca/bin/certool --gencert --privkey=vpxd.priv --cert vpxd.crt --Name=VPXD_1 --config
 sol_usr.cfg
```

3. Find the name for each solution user.

```
/usr/lib/vmware-vmafd/bin/dir-cli service list
```

   You can use the unique ID that is returned when you replace the certificates. The input and output might look as follows.

```
/usr/lib/vmware-vmafd/bin/dir-cli service list
Enter password for administrator@vsphere.local:
1. machine-623bef28-0311-436e-b21f-6e0d39aa5179
```

2. vsphere-webclient-623bef28-0311-436e-b21f-6e0d39aa5179
3. vpxd-623bef28-0311-436e-b21f-6e0d39aa5179
4. vpxd-extension-623bef28-0311-436e-b21f-6e0d39aa5179
5. hvc-623bef28-0311-436e-b21f-6e0d39aa5179
6. wcp-1cbe0a40-e4ce-4378-b5e7-9460e2b8200e

In a deployment of multiple vCenter instances connected in Enhanced Linked Mode configuration, the output of `/usr/lib/vmware-vmafd/bin/dir-cli service list` includes all solution users from all nodes. Run `/usr/lib/vmware-vmafd/bin/vmafd-cli get-machine-id --server-name localhost` to find the local machine ID for each host. Each solution user name includes the machine ID.

4. Stop all services and start the services that handle certificate creation, propagation, and storage.

```
service-control --stop --all
service-control --start vmafdd
service-control --start vmdird
service-control --start vmcad
```

5. For each solution user, replace the existing certificate in vmdir and then in VECS.

   The following example shows how to replace the certificates for the vpxd service.

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name <vpxd-xxxx-xxx-7c7b769cd9f4> --cert ./vpxd.crt
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store vpxd --alias vpxd
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store vpxd --alias vpxd --cert vpxd.crt --key vpxd.priv
```

   Note:
   Solution users cannot authenticate to vCenter Single Sign-On if you do not replace the certificate in vmdir.

6. Restart all services.

```
service-control --start --all
```

Using VMCA-Signed Solution User Certificates

1. Generate a public/private key pair for each solution user on each vCenter node in an Enhanced Linked Mode configuration. That includes a pair for the machine solution and a pair for each additional solution user (vpxd, vpxd-extension, vsphere-webclient, wcp).
   a. Generate a key pair for the machine solution user.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=machine-key.priv --pubkey=machine-key.pub
      ```
   b. Generate a key pair for the vpxd solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=vpxd-key.priv --pubkey=vpxd-key.pub
      ```
   c. Generate a key pair for the vpxd-extension solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=vpxd-extension-key.priv --pubkey=vpxd-extension-key.pub
      ```
   d. Generate a key pair for the vsphere-webclient solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=vsphere-webclient-key.priv --pubkey=vsphere-webclient-key.pub
      ```
   e. Generate a key pair for the wcp solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=wcp-key.priv --pubkey=wcp-key.pub
      ```
2. Generate solution user certificates that are signed by the new VMCA root certificate for the machine solution user and for each additional solution user (vpxd, vpxd-extension, vsphere-webclient, wcp) on each vCenter node.

   Note:
   The `--Name` parameter has to be unique. Including the name of the solution user store name makes it easy to see which certificate maps to which solution user. The example includes the name, for example vpxd or vpxd-extension in each case.
   a. Make one copy of the `/usr/lib/vmware-vmca/share/config/certool.cfg` file, then modify or remove the Name, IP address, DNS name, and email fields as required, and rename the file, for example, to `sol_usr.cfg`.

b. Generate a certificate for the machine solution user on each node.

```
/usr/lib/vmware-vmca/bin/certool --gencert --cert=new-machine.crt --privkey=machine-key.priv
 --Name=machine --config sol_usr.cfg
```

c. Generate a certificate for the vpxd solution user on each node.

```
/usr/lib/vmware-vmca/bin/certool --gencert --cert=new-vpxd.crt --privkey=vpxd-key.priv --
Name=vpxd --config sol_usr.cfg
```

d. Generate a certificate for the vpxd-extensions solution user on each node.

```
/usr/lib/vmware-vmca/bin/certool --gencert --cert=new-vpxd-extension.crt --privkey=vpxd-
extension-key.priv --Name=vpxd-extension --config sol_usr.cfg
```

e. Generate a certificate for the vsphere-webclient solution user on each node by running the following command.

```
/usr/lib/vmware-vmca/bin/certool --gencert --cert=new-vsphere-webclient.crt --
privkey=vsphere-webclient-key.priv --Name=vsphere-webclient --config sol_usr.cfg
```

f. Generate a certificate for the wcp solution user on each node by running the following command.

```
/usr/lib/vmware-vmca/bin/certool --gencert --cert=new-wcp.crt --privkey=wcp-key.priv --
Name=wcp --config sol_usr.cfg
```

3. Replace the solution user certificates in VECS with the new solution user certificates.

Note:
The `--store` and `--alias` parameters have to exactly match the default names for services.

a. Replace the machine solution user certificate on each node:

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store machine --alias machine
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store machine --alias machine --cert new-
machine.crt --key machine-key.priv
```

b. Replace the vpxd solution user certificate on each node.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store vpxd --alias vpxd
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store vpxd --alias vpxd --cert new-
vpxd.crt --key vpxd-key.priv
```

c. Replace the vpxd-extension solution user certificate on each node.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store vpxd-extension --alias vpxd-
extension
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store vpxd-extension --alias vpxd-
extension --cert new-vpxd-extension.crt --key vpxd-extension-key.priv
```

d. Replace the vsphere-webclient solution user certificate on each node.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store vsphere-webclient --alias vsphere-
webclient
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store vsphere-webclient --alias vsphere-
webclient --cert new-vsphere-webclient.crt --key vsphere-webclient-key.priv
```

e. Replace the wcp solution user certificate on each node.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store wcp --alias wcp
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store wcp --alias wcp --cert new-wcp.crt
 --key wcp-key.priv
```

4. Update VMware Directory Service (vmdir) with the new solution user certificates. You are prompted for a vCenter Single Sign-On administrator password.

a. Run `/usr/lib/vmware-vmafd/bin/dir-cli service list` to get the unique service ID suffix for each solution user. You run this command on a vCenter system.

```
/usr/lib/vmware-vmafd/bin/dir-cli service list
output:
1. machine-623bef28-0311-436e-b21f-6e0d39aa5179
2. vsphere-webclient-623bef28-0311-436e-b21f-6e0d39aa5179
3. vpxd-623bef28-0311-436e-b21f-6e0d39aa5179
4. vpxd-extension-623bef28-0311-436e-b21f-6e0d39aa5179
5. hvc-623bef28-0311-436e-b21f-6e0d39aa5179
6. wcp-1cbe0a40-e4ce-4378-b5e7-9460e2b8200e
```

Note:
When you list solution user certificates in large deployments, the output of `/usr/lib/vmware-vmafd/bin/dir-cli list` includes all solution users from all nodes. Run `/usr/lib/vmware-vmafd/bin/vmafd-cli get-machine-id --server-name localhost` to find the local machine ID for each host. Each solution user name includes the machine ID.

b. Replace the machine certificate in vmdir on each vCenter node. For example, if machine-6fd7f140-60a9-11e4-9e28-005056895a69 is the machine solution user on the vCenter, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name
 machine-6fd7f140-60a9-11e4-9e28-005056895a69 --cert new-machine.crt
```

c. Replace the vpxd solution user certificate in vmdir on each node. For example, if vpxd-6fd7f140-60a9-11e4-9e28-005056895a69 is the vpxd solution user ID, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name
 vpxd-6fd7f140-60a9-11e4-9e28-005056895a69 --cert new-vpxd.crt
```

d. Replace the vpxd-extension solution user certificate in vmdir on each node. For example, if vpxd-extension-6fd7f140-60a9-11e4-9e28-005056895a69 is the vpxd-extension solution user ID, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name vpxd-
extension-6fd7f140-60a9-11e4-9e28-005056895a69 --cert new-vpxd-extension.crt
```

e. Replace the vsphere-webclient solution user certificate on each node. For example, if vsphere-webclient-6fd7f140-60a9-11e4-9e28-005056895a69 is the vsphere-webclient solution user ID, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name vsphere-
webclient-6fd7f140-60a9-11e4-9e28-005056895a69 --cert new-vsphere-webclient.crt
```

f. Replace the wcp solution user certificate on each node. For example, if wcp-1cbe0a40-e4ce-4378-b5e7-9460e2b8200e is the wcp solution user ID, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name wcp-1cbe0a40-e4ce-4378-
b5e7-9460e2b8200e --cert new-wcp.crt
```

Restart all services on each vCenter node.

Make VMCA Into an Intermediate Certificate Authority Using the CLI

You can use the CLI to replace the VMCA root certificate with a third-party CA-signed certificate that includes VMCA in the certificate chain. Going forward, all certificates that VMCA generates include the full chain. You can replace existing certificates with newly generated certificates.

If you use VMCA as an intermediate CA, or use custom certificates, you might encounter significant complexity and the potential for a negative impact to your security, and an unnecessary increase in your operational risk. For more information about managing certificates within a vSphere environment, see the blog post titled *New Product Walkthrough - Hybrid vSphere SSL Certificate Replacement* at https://blogs.vmware.com/vsphere/2017/01/walkthrough-hybrid-ssl-certificate-replacement.html.

Replace the Root Certificate (Intermediate CA) Using the CLI

The first step in replacing the VMCA certificates with custom certificates is generating a CSR, and sending the CSR to be signed. You then use the CLI to add the signed certificate to VMCA as a root certificate.

You can use the Certificate Manager utility or other tool to generate the CSR. The CSR must meet the following requirements:

- Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded)
- PEM format. VMware supports PKCS8 and PKCS1 (RSA keys). When keys are added to VECS, they are converted to PKCS8.
- x509 version 3
- The CA extension must be set to true for root certificates, and cert sign must be in the list of requirements. For example:

```
basicConstraints        = critical,CA:true
keyUsage                = critical,digitalSignature,keyCertSign
```

- CRL signing must be enabled.
- Extended Key Usage can be either empty or contain Server Authentication.
- No explicit limit to the length of the certificate chain. VMCA uses the OpenSSL default, which is 10 certificates.
- Certificates with wildcards or with more than one DNS name are not supported.
- You cannot create subsidiary CAs of VMCA.

  See the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2112009, Creating a Microsoft Certificate Authority Template for SSL certificate creation in vSphere 6.x, for an example using Microsoft Certificate Authority.

  Note:
  vSphere's FIPS certificate only validates RSA key sizes of 2048 bits and 3072 bits.

VMCA validates the following certificate attributes when you replace the root certificate:

- Key size: 2048 bits (minimum) to 8192 bits (maximum).
- Key Usage: Cert Sign
- Basic Constraint: Subject Type CA

1. Generate a CSR and send it to your CA.

   Follow your CA's instructions.

2. Prepare a certificate file that includes the signed VMCA certificate and the full CA chain of your third-party CA or enterprise CA. Save the file, for example as `rootca1.crt`.

   You can accomplish this step by copying all CA certificates in PEM format into a single file. You start with the VMCA root certificate and end up with the root CA PEM certificate. For example:

   ```
   -----BEGIN CERTIFICATE-----
   <Certificate of VMCA>
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   <Certificate of intermediary CA>
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   <Certificate of Root CA>
   -----END CERTIFICATE-----
   ```

3. Stop all services and start the services that handle certificate creation, propagation, and storage.

   ```
   service-control --stop --all
   service-control --start vmafdd
   service-control --start vmdird
   service-control --start vmcad
   ```

4. Replace the existing VMCA root CA.

   ```
   certool --rootca --cert=rootca1.crt --privkey=root1.key
   ```

   When you run this command, it:

   - Adds the new custom root certificate to the certificate location in the file system.
   - Appends the custom root certificate to the TRUSTED_ROOTS store in VECS (after a delay).
   - Adds the custom root certificate to vmdir (after a delay).

5. Optional: To propagate the change to all instances of vmdir (VMware Directory Service), publish the new root certificate to vmdir, supplying the full file path for each file.

   For example, if the certificate has only one certificate in the chain:

   ```
   dir-cli trustedcert publish --cert rootca1.crt
   ```

   If the certificate has more than one certificate in the chain:

   ```
   dir-cli trustedcert publish --cert rootca1.crt --chain
   ```

Replication between vmdir nodes happens every 30 seconds. You do not have to add the root certificate to VECS explicitly because VECS polls vmdir for new root certificate files every 5 minutes.

6. Optional: If necessary, you can force a refresh of VECS.

```
vecs-cli force-refresh
```

7. Restart all services.

```
service-control --start --all
```

Replacing the Root Certificate

Replace the VMCA root certificate with the custom CA root certificate using the `certool` command with the `--rootca` option.

```
/usr/lib/vmware-vmca/bin/certool --rootca --cert=<path>/root.pem --privkey=<path>/root.key
```

When you run this command, it:

- Adds the new custom root certificate to the certificate location in the file system.
- Appends the custom root certificate to the TRUSTED_ROOTS store in VECS.
- Adds the custom root certificate to vmdir.

You can remove the original VMCA root certificate from the certificate store if your company policy requires it. If you do, you have to replace the vCenter Single Sign-On Signing certificate. See Replace a vCenter STS Certificate Using the Command Line.

Replace Machine SSL Certificates (Intermediate CA) Using the CLI

After you have received the signed certificate from the CA, you can use the CLI to make it the VMCA root certificate and replace all machine SSL certificates.

For each machine SSL certificate, the `SubjectAltName` must contain `DNS Name=<Machine FQDN>`.

These steps are essentially the same as the steps for replacing with a certificate that uses VMCA as the certificate authority. However, in this case, VMCA signs all certificates with the full chain.

Each machine must have a machine SSL certificate for secure communication with other services. When multiple vCenter instances are connected in Enhanced Linked Mode configuration, you must run the Machine SSL certificate generation commands on each node.

1. Make one copy of `certool.cfg` for each machine that needs a new certificate.

   The `certool.cfg` file is located in the `/usr/lib/vmware-vmca/share/config/` directory.

2. Edit the custom configuration file for each machine to include that machine's FQDN.

   Run `NSLookup` against the machine's IP address to see the DNS listing of the name, and use that name for the Hostname field in the file.

3. Generate a public/private key file pair and a certificate for each machine, passing in the configuration file that you just customized.

   For example:

```
certool --genkey --privkey=machine1.priv --pubkey=machine1.pub
certool --gencert --privkey=machine1.priv --cert machine42.crt --Name=Machine42_Cert --config machine1.cfg
```

4. Stop all services and start the services that handle certificate creation, propagation, and storage.

```
service-control --stop --all
service-control --start vmafdd
service-control --start vmdird
service-control --start vmcad
```

5. Add the new certificate to VECS.

   All machines need the new certificate in the local certificate store to communicate over SSL. You first delete the existing entry, then add the new entry.

```
vecs-cli entry delete --store MACHINE_SSL_CERT --alias __MACHINE_CERT
vecs-cli entry create --store MACHINE_SSL_CERT --alias __MACHINE_CERT --cert machine1.cert
--key machine1.priv
```

6. Restart all services.

```
service-control --start --all
```

Replacing Machine SSL Certificates (VMCA Is Intermediate CA)

1. Create a configuration file for the SSL certificate and save it as `ssl-config.cfg` in the current directory.

```
Country = US
Name = vmca-<FQDN-example>
Organization = VMware
OrgUnit = VMware Engineering
State = California
Locality = Palo Alto
Hostname = <FQDN>
```

2. Generate a key pair for the machine SSL certificate. In a deployment of multiple vCenter instances connected in Enhanced Linked Mode configuration, run this command on each vCenter node.

```
/usr/lib/vmware-vmca/bin/certool --genkey --privkey=ssl-key.priv --pubkey=ssl-key.pub
```

   The `ssl-key.priv` and `ssl-key.pub` files are created in the current directory.

3. Generate the new machine SSL certificate. This certificate is signed by VMCA. If you replaced the VMCA root certificate with custom certificate, VMCA signs all certificates with the full chain.

```
/usr/lib/vmware-vmca/bin/certool --gencert --cert=new-vmca-ssl.crt --privkey=ssl-key.priv --
config=ssl-config.cfg
```

   The `new-vmca-ssl.crt` file is created in the current directory.

4. (Optional) List the content of VECS.

```
/usr/lib/vmware-vmafd/bin/vecs-cli store list
```

   – Sample output on vCenter:

```
output (on vCenter):
MACHINE_SSL_CERT
TRUSTED_ROOTS
TRUSTED_ROOT_CRLS
machine
vsphere-webclient
vpxd
vpxd-extension
hvc
data-encipherment
APPLMGMT_PASSWORD
SMS
wcp
KMS_ENCRYPTION
```

5. Replace the Machine SSL certificate in VECS with the new Machine SSL certificate. The `--store` and `--alias` values have to exactly match with the default names.

   – On each vCenter, run the following commands to update the Machine SSL certificate in the MACHINE_SSL_CERT store. You must update the certificate for each machine separately because each has a different FQDN.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store MACHINE_SSL_CERT --alias
 __MACHINE_CERT
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store MACHINE_SSL_CERT --alias
 __MACHINE_CERT --cert new-vmca-ssl.crt --key ssl-key.priv
```

Replace Solution User Certificates (Intermediate CA) Using the CLI

After you replace the machine SSL certificates, you can use the CLI to replace the solution user certificates.

Each solution user certificate must have a different `Subject`. Consider, for example, including the solution user name (such as vpxd) or other unique identifier.

Many VMware customers do not replace solution user certificates. They replace only the machine SSL certificates with custom certificates. This hybrid approach satisfies the requirements of their security teams.

- Certificates either sit behind a proxy, or they are custom certificates.
- No intermediate CAs are used.

You replace the machine solution user certificate and the solution user certificate on each vCenter system.

> **Note:**
> When you list solution user certificates in large deployments, the output of `/usr/lib/vmware-vmafd/bin/dir-cli list` includes all solution users from all nodes. Run `/usr/lib/vmware-vmafd/bin/vmafd-cli get-machine-id --server-name localhost` to find the local machine ID for each host. Each solution user name includes the machine ID.

1. Make one copy of `certool.cfg`, remove the Name, IP address, DNS name, and email fields, and rename the file, for example, to `sol_usr.cfg`.

   You can name the certificates from the command line as part of generation. The other information is not needed for solution users. If you leave the default information, the certificates that are generated are potentially confusing.

2. Generate a public/private key file pair and a certificate for each solution user, passing in the configuration file that you just customized.

   For example:

   ```
   certool --genkey --privkey=vpxd.priv --pubkey=vpxd.pub
   certool --gencert --privkey=vpxd.priv --cert vpxd.crt --Name=VPXD_1 --config sol_usr.cfg
   ```

3. Find the name for each solution user.

   ```
   /usr/lib/vmware-vmafd/bin/dir-cli service list
   ```

   You can use the unique ID that is returned when you replace the certificates. The input and output might look as follows.

   ```
   /usr/lib/vmware-vmafd/bin/dir-cli service list
   Enter password for administrator@vsphere.local:
   1. machine-623bef28-0311-436e-b21f-6e0d39aa5179
   2. vsphere-webclient-623bef28-0311-436e-b21f-6e0d39aa5179
   3. vpxd-623bef28-0311-436e-b21f-6e0d39aa5179
   4. vpxd-extension-623bef28-0311-436e-b21f-6e0d39aa5179
   5. hvc-623bef28-0311-436e-b21f-6e0d39aa5179
   6. wcp-1cbe0a40-e4ce-4378-b5e7-9460e2b8200e
   ```

   In a deployment of multiple vCenter instances connected in Enhanced Linked Mode configuration, the output of `/usr/lib/vmware-vmafd/bin/dir-cli service list` includes all solution users from all nodes. Run `/usr/lib/vmware-vmafd/bin/vmafd-cli get-machine-id --server-name localhost` to find the local machine ID for each host. Each solution user name includes the machine ID.

4. Stop all services and start the services that handle certificate creation, propagation, and storage.

   ```
   service-control --stop --all
   service-control --start vmafdd
   service-control --start vmdird
   service-control --start vmcad
   ```

5. Replace the existing certificate in vmdir and then in VECS.

   For solution users, you must add the certificates in that order. For example:

   ```
   dir-cli service update --name <vpxd-xxxx-xxx-7c7b769cd9f4> --cert ./vpxd.crt
   vecs-cli entry delete --store vpxd --alias vpxd
   vecs-cli entry create --store vpxd --alias vpxd --cert vpxd.crt --key vpxd.priv
   ```

Note:

Solution users cannot log in to vCenter Single Sign-On if you do not replace the certificate in vmdir.

6. Restart all services.

```
service-control --start --all
```

Replacing Solution User Certificates (Intermediate CA)

1. Generate a public/private key pair for each solution user on each vCenter node in an Enhanced Linked Mode configuration. That includes a pair for the machine solution and a pair for each additional solution user (vpxd, vpxd-extension, vsphere-webclient, wcp).
   a. Generate a key pair for the machine solution user.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=machine-key.priv --pubkey=machine-key.pub
      ```
   b. Generate a key pair for the vpxd solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=vpxd-key.priv --pubkey=vpxd-key.pub
      ```
   c. Generate a key pair for the vpxd-extension solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=vpxd-extension-key.priv --pubkey=vpxd-extension-key.pub
      ```
   d. Generate a key pair for the vsphere-webclient solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=vsphere-webclient-key.priv --pubkey=vsphere-webclient-key.pub
      ```
   e. Generate a key pair for the wcp solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --genkey --privkey=wcp-key.priv --pubkey=wcp-key.pub
      ```
2. Generate solution user certificates that are signed by the new VMCA root certificate for the machine solution user and for each additional solution user (vpxd, vpxd-extension, vsphere-webclient, wcp) on each vCenter node.

   Note:
   The `--Name` parameter has to be unique. Including the name of the solution user store name makes it easy to see which certificate maps to which solution user. The example includes the name, for example vpxd or vpxd-extension in each case.
   a. Make one copy of the `/usr/lib/vmware-vmca/share/config/certool.cfg` file, then modify or remove the Name, IP address, DNS name, and email fields as required, and rename the file, for example, to `sol_usr.cfg`.
   b. Generate a certificate for the machine solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --gencert --cert=new-machine.crt --privkey=machine-key.priv
       --Name=machine --config sol_usr.cfg
      ```
   c. Generate a certificate for the vpxd solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --gencert --cert=new-vpxd.crt --privkey=vpxd-key.priv --
      Name=vpxd --config sol_usr.cfg
      ```
   d. Generate a certificate for the vpxd-extensions solution user on each node.
      ```
      /usr/lib/vmware-vmca/bin/certool --gencert --cert=new-vpxd-extension.crt --privkey=vpxd-extension-key.priv --Name=vpxd-extension --config sol_usr.cfg
      ```
   e. Generate a certificate for the vsphere-webclient solution user on each node by running the following command.
      ```
      /usr/lib/vmware-vmca/bin/certool --gencert --cert=new-vsphere-webclient.crt --
      privkey=vsphere-webclient-key.priv --Name=vsphere-webclient --config sol_usr.cfg
      ```
   f. Generate a certificate for the wcp solution user on each node by running the following command.
      ```
      /usr/lib/vmware-vmca/bin/certool --gencert --cert=new-wcp.crt --privkey=wcp-key.priv --
      Name=wcp --config sol_usr.cfg
      ```
3. Replace the solution user certificates in VECS with the new solution user certificates.

   Note:
   The `--store` and `--alias` parameters have to exactly match the default names for services.

a. Replace the machine solution user certificate on each node:

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store machine --alias machine
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store machine --alias machine --cert new-machine.crt --key machine-key.priv
```

b. Replace the vpxd solution user certificate on each node.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store vpxd --alias vpxd
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store vpxd --alias vpxd --cert new-vpxd.crt --key vpxd-key.priv
```

c. Replace the vpxd-extension solution user certificate on each node.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store vpxd-extension --alias vpxd-extension
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store vpxd-extension --alias vpxd-extension --cert new-vpxd-extension.crt --key vpxd-extension-key.priv
```

d. Replace the vsphere-webclient solution user certificate on each node.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store vsphere-webclient --alias vsphere-webclient
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store vsphere-webclient --alias vsphere-webclient --cert new-vsphere-webclient.crt --key vsphere-webclient-key.priv
```

e. Replace the wcp solution user certificate on each node.

```
/usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store wcp --alias wcp
/usr/lib/vmware-vmafd/bin/vecs-cli entry create --store wcp --alias wcp --cert new-wcp.crt
 --key wcp-key.priv
```

4. Update VMware Directory Service (vmdir) with the new solution user certificates. You are prompted for a vCenter Single Sign-On administrator password.

a. Run `/usr/lib/vmware-vmafd/bin/dir-cli service list` to get the unique service ID suffix for each solution user. You run this command on a vCenter system.

```
/usr/lib/vmware-vmafd/bin/dir-cli service list
output:
1. machine-623bef28-0311-436e-b21f-6e0d39aa5179
2. vsphere-webclient-623bef28-0311-436e-b21f-6e0d39aa5179
3. vpxd-623bef28-0311-436e-b21f-6e0d39aa5179
4. vpxd-extension-623bef28-0311-436e-b21f-6e0d39aa5179
5. hvc-623bef28-0311-436e-b21f-6e0d39aa5179
6. wcp-1cbe0a40-e4ce-4378-b5e7-9460e2b8200e
```

Note:
When you list solution user certificates in large deployments, the output of `/usr/lib/vmware-vmafd/bin/dir-cli list` includes all solution users from all nodes. Run `/usr/lib/vmware-vmafd/bin/vmafd-cli get-machine-id --server-name localhost` to find the local machine ID for each host. Each solution user name includes the machine ID.

b. Replace the machine certificate in vmdir on each vCenter node. For example, if machine-6fd7f140-60a9-11e4-9e28-005056895a69 is the machine solution user on the vCenter, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name
 machine-6fd7f140-60a9-11e4-9e28-005056895a69 --cert new-machine.crt
```

c. Replace the vpxd solution user certificate in vmdir on each node. For example, if vpxd-6fd7f140-60a9-11e4-9e28-005056895a69 is the vpxd solution user ID, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name
 vpxd-6fd7f140-60a9-11e4-9e28-005056895a69 --cert new-vpxd.crt
```

d. Replace the vpxd-extension solution user certificate in vmdir on each node. For example, if vpxd-extension-6fd7f140-60a9-11e4-9e28-005056895a69 is the vpxd-extension solution user ID, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name vpxd-
extension-6fd7f140-60a9-11e4-9e28-005056895a69 --cert new-vpxd-extension.crt
```

e. Replace the vsphere-webclient solution user certificate on each node. For example, if vsphere-webclient-6fd7f140-60a9-11e4-9e28-005056895a69 is the vsphere-webclient solution user ID, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name vsphere-
webclient-6fd7f140-60a9-11e4-9e28-005056895a69 --cert new-vsphere-webclient.crt
```

f. Replace the wcp solution user certificate on each node. For example, if wcp-1cbe0a40-e4ce-4378-b5e7-9460e2b8200e is the wcp solution user ID, run this command:

```
/usr/lib/vmware-vmafd/bin/dir-cli service update --name wcp-1cbe0a40-e4ce-4378-
b5e7-9460e2b8200e --cert new-wcp.crt
```

Replace Certificates with Custom Certificates Using the CLI

If your company policy requires it, you can use the CLI to replace some or all certificates used in vSphere with certificates that are signed by a third-party or enterprise CA. If you do that, VMCA is not in your certificate chain. You are responsible for storing all vCenter certificates in VECS.

You can replace all certificates or use a hybrid solution. For example, consider replacing all certificates that are used for network traffic but leaving VMCA-signed solution user certificates. Solution user certificates are used only for authentication to vCenter Single Sign-On. vCenter uses solution user certificates for internal communication only. Solution user certificates are not used for external communication.

Note:
If you do not want to use VMCA, you are responsible for replacing all certificates yourself, for provisioning new components with certificates, and for tracking certificate expiration.

Even if you decide to use custom certificates, you can still use the VMware Certificate Manager utility for certificate replacement. See Replace All Certificates with a Custom Certificate Using the Certificate Manager.

Request Certificates and Import a Custom Root Certificate Using the CLI

You can use custom certificates from an enterprise or third-party CA. The first step is requesting the certificates from the certificate authority then using the CLI to import the root certificates into VMware Endpoint Certificate Store (VECS).

The certificate must meet the following requirements:

- Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded)
- PEM format. VMware supports PKCS8 and PKCS1 (RSA keys). When keys are added to VECS, they are converted to PKCS8.
- x509 version 3
- For root certificates, the CA extension must be set to true, and the cert sign must be in the list of requirements.
- SubjectAltName must contain DNS Name=<machine_FQDN>.
- CRT format
- Contains the following Key Usages: Digital Signature, Key Encipherment
- Start time of one day before the current time.
- CN (and SubjectAltName) set to the host name (or IP address) that the ESX host has in the vCenter inventory.

Note:
vSphere's FIPS certificate only validates RSA key sizes of 2048 bits and 3072 bits.

1. Send the Certificate Signing Requests (CSRs) for the following certificates to your enterprise or third-party certificate provider.
   - A machine SSL certificate for each machine. For the machine SSL certificate, the SubjectAltName field must contain the fully qualified domain name (DNS NAME=*machine_FQDN*).
   - Optionally, five solution user certificates for each node. Solution user certificates do not need to include IP address, host name, or email address. Each certificate must have a different certificate Subject.

   Typically, the result is a PEM file for the trusted chain, plus the signed SSL certificates for each vCenter node.

2. List the TRUSTED_ROOTS and the machine SSL stores.

   ```
   vecs-cli store list
   ```

   a) Ensure that the current root certificate and all machine SSL certificates are signed by VMCA.
   b) Note down the Serial number, issuer, and Subject CN fields.
   c) Optional: With a Web browser, open an HTTPS connection to a node where the certificate is to be replaced, view the certificate information, and ensure that it matches the machine SSL certificate.

3. Stop all services and start the services that handle certificate creation, propagation, and storage.

   ```
   service-control --stop --all
   service-control --start vmafdd
   service-control --start vmdird
   service-control --start vmcad
   ```

4. Publish the custom root certificate.

   ```
   dir-cli trustedcert publish --cert <my_custom_root>
   ```

   If you do not specify a user name and password on the command line, you are prompted.

5. Restart all services.

   ```
   service-control --start --all
   ```

You can remove the original VMCA root certificate from the certificate store if your company policy requires it. If you do, you have to refresh the vCenter Single Sign-On certificate. See Replace a vCenter STS Certificate Using the Command Line.

Replace Machine SSL Certificates with Custom Certificates Using the CLI

After you receive the custom certificates, you can use the CLI to replace each machine certificate.

You must have received a certificate for each machine from your third-party or enterprise CA.

- Key size: 2048 bits (minimum) to 8192 bits (maximum) (PEM encoded)
- CRT format
- x509 version 3
- SubjectAltName must contain DNS Name=<machine_FQDN>.
- Contains the following Key Usages: Digital Signature, Key Encipherment

Perform the steps on each vCenter host.

You must have the following information before you can start replacing the certificates:

- Password for administrator@vsphere.local
- Valid Machine SSL custom certificate (`.crt` file)
- Valid Machine SSL custom key (`.key` file)
- Valid custom certificate for Root (`.crt` file)

1. Back up the current machine SSL certificate.

   ```
   /usr/lib/vmware-vmafd/bin/vecs-cli entry getcert --store MACHINE_SSL_CERT --alias __MACHINE_CERT >
    oldmachine.crt
   /usr/lib/vmware-vmafd/bin/vecs-cli entry getkey --store MACHINE_SSL_CERT --alias __MACHINE_CERT >
    oldmachinekey.key
   ```

2. Log in to each host and add the new machine certificates that you received from the certificate authority to VECS.

   All hosts need the new certificate in the local certificate store to communicate over SSL.

   a) Delete the existing certificate.

      ```
      /usr/lib/vmware-vmafd/bin/vecs-cli entry delete --store MACHINE_SSL_CERT --alias __MACHINE_CERT
      ```

   b) Add the new certificate.

      ```
      /usr/lib/vmware-vmafd/bin/vecs-cli entry create --store MACHINE_SSL_CERT --alias __MACHINE_CERT --cert
       <cert-file-path> --key <key-file-path>
      ```

3. Extract the hash of the old certificate to be replaced.

   ```
   openssl x509 -in <path_to_old_machinessl_certificate> -noout -sha1 -fingerprint
   ```

   Output similar to the following appears:

   ```
   SHA1 Fingerprint=13:1E:60:93:E4:E6:59:31:55:EB:74:51:67:2A:99:F8:3F:04:83:88
   ```

4. Update the lookup service registration endpoint manually.

   ```
   /usr/lib/vmware-lookupsvc/tools/ls_update_certs.py --url https://<vCenterServer_FQDN>/lookupservice/sdk
    --certfile <cert-file-path> --user 'administrator@vsphere.local' --password '<password>' --fingerprint
    <SHA1_hash_of_the_old_certificate_to_replace>
   ```

   If you encounter problems running `ls_update_certs.py`, see thenowledge base article at http://knowledge.broadcom.com/external/article?legacyId=95982.

5. Restart all services.

   ```
   service-control --stop --all && service-control --start --all
   ```

vSphere Certificates and Services CLI Command Reference

You can manage VMCA (VMware Certificate Authority), VECS (VMware Endpoint Certificate Store), VMware Directory Service (vmdir), and Security Token Service (STS) certificates by using a set of CLIs. The vSphere Certificate Manager utility supports many related tasks as well, but the CLIs are required for manual certificate management and for managing other services.

You normally access the CLI tools for managing certificates and associated services by using SSH to connect to the appliance shell. See the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2100508 for more information.

Manual vSphere Certificate Replacement gives examples for replacing certificates using CLI commands.

Table 85: vSphere CLI Tools for Managing Certificates and Associated Services

CLI	Description	See
`certool`	Generate and manage certificates and keys. Part of VMCAD, the VMware Certificate Management service.	certool Initialization Commands Reference
`vecs-cli`	Manage the contents of VMware Certificate Store instances. Part of VMware Authentication Framework Daemon (VMAFD).	vecs-cli Command Reference
`dir-cli`	Create and update certificates in VMware Directory Service. Part of VMAFD.	dir-cli Command Reference
`sso-config.sh`	Manage STS certificates.	Command-line help. Entering `sso-config.sh` with no options displays the command-line help.
`service-control`	Start or stop services, for example as part of a certificate replacement workflow.	Run this command to stop services before running other CLI commands.

vSphere CLI Locations

By default, you find the CLIs in the following locations.

```
/usr/lib/vmware-vmafd/bin/vecs-cli
/usr/lib/vmware-vmafd/bin/dir-cli
/usr/lib/vmware-vmca/bin/certool
/opt/vmware/bin/sso-config.sh
```

Note:
The `service-control` command does not require that you specify the path.

Required Privileges for Running vSphere CLIs

Required privileges depend on the CLI that you are using and on the command that you want to run. For example, for most certificate management operations, you have to be an administrator for the local vCenter Single Sign-On domain (vsphere.local by default). Some commands are available for all users.

dir-cli	You must be a member of the Administrators group in the local domain (vsphere.local by default) to run `dir-cli` commands. If you do not specify a user name and password, you are prompted for the password for the administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
vecs-cli	Initially, only the store owner and users with blanket access privileges have access to a store. Users in the Administrators group have blanket access privileges. The MACHINE_SSL_CERT and TRUSTED_ROOTS stores are special stores. Only the root user or the administrator user, depending on the type of installation, has complete access.
certool	Most of the `certool` commands require that the user is in the Administrators group. All users can run the following commands. • `genselfcacert` • `initscr` • `getdc` • `waitVMDIR` • `waitVMCA` • `genkey` • `viewcert`

Changing the certool Configuration Options

When you run `certool --gencert` or certain other certificate initialization or management commands, the command reads all the values from a configuration file. You can edit the existing file, override the default configuration file with the `--config=<file name>` option, or override values on the command line.

The configuration file, `certool.cfg`, is located in the `/usr/lib/vmware-vmca/share/config/` directory by default.

The file has several fields with the following default values:

```
Country = US
Name= Acme
Organization = AcmeOrg
OrgUnit = AcmeOrg Engineering
State = California
Locality = Palo Alto
IPAddress = 127.0.0.1
Email = email@acme.com
Hostname = server.acme.com
```

Note:
The OU (organizationalUnitName) field is no longer mandatory.

You can change the values by specifying a modified file on the command line, or by overriding individual values on the command line, as follows.

- Create a copy of the configuration file and edit the file. Use the --config command-line option to specify the file. Specify the full path to avoid path name issues.
- `/usr/lib/vmware-vmca/bin/certool --gencert --config /tmp/myconfig.cfg`
- Override individual values on the command line. For example, to override Locality, run this command:
  `/usr/lib/vmware-vmca/bin/certool --gencert --privkey=private.key --Locality="Mountain View"`

Specify `--Name` to replace the CN field of the Subject name of the certificate.

- For solution user certificates, the name is <sol_user name>@<domain> by convention, but you can change the name if a different convention is used in your environment.
- For machine SSL certificates, the FQDN of the machine is used.
  VMCA allows only one DNSName (in the `Hostname` field) and no other Alias options. If the IP address is specified by the user, it is stored in SubAltName as well.

Use the `--Hostname` parameter to specify the DNSName of a certificate's SubAltName.

certool Initialization Commands Reference

The `certool` initialization commands allow you to generate certificate signing requests, view and generate certificates and keys that are signed by VMware Certificate Authority (VMCA), import root certificates, and perform other certificate management operations.

In many cases, you pass a configuration file in to a `certool` command. See vSphere Certificates and Services CLI Command Reference. See Replace Existing VMCA-Signed Certificates with New VMCA-Signed Certificates Using the CLI for some usage examples. The command-line help provides details about the options.

certool --initcsr

Generates a Certificate Signing Request (CSR). The command generates a PKCS10 file and a private key.

Option	Description
--gencsr	Required for generating CSRs.
--privkey <key_file>	Name of the private key file.
--pubkey <key_file>	Name of the public key file.
--csrfile <csr_file>	File name for the CSR file to be sent to the CA provider.
--config <config_file>	Name of the configuration file. A sample configuration file is located at `/usr/lib/vmware-vmca/share/config/certool.cfg`. As a best practice, make a copy of the default configuration file and replace the required fields.

Example:

```
certool --gencsr --privkey=<filename> --pubkey=<filename> --csrfile=<filename>
```

certool --selfca

Creates a self-signed certificate and provisions the VMCA server with a self-signed root CA. Using this option is one of the simplest ways to provision the VMCA server. You can instead provision the VMCA server with a third-party root certificate so that VMCA is an intermediate CA. See Make VMCA Into an Intermediate Certificate Authority Using the CLI.

This command generates a certificate that is predated by three days to avoid time zone conflicts.

Option	Description
--selfca	Required for generating a self-signed certificate.
--predate <number_of_minutes>	Allows you to set the Valid Not Before field of the root certificate to the specified number of minutes before the current time. This option can be helpful to account for potential time zone issues. The maximum is three days.
--config <config_file>	Name of the configuration file. A sample configuration file is located at `/usr/lib/vmware-vmca/share/config/certool.cfg`. As a best practice, make a copy of the default configuration file and replace the required fields.
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.

Example:

```
machine-70-59:/usr/lib/vmware-vmca/bin # ./certool --predate=2280  --selfca --server= 192.0.2.24 --srp-
upn=administrator@vsphere.local
```

certool --rootca

Imports a root certificate. Adds the specified certificate and private key to VMCA. VMCA always uses the most recent root certificate for signing, but other root certificates remain trusted until you manually delete them. That means you can update your infrastructure one step at a time, and finally delete certificates that you no longer use.

Option	Description
--rootca	Required for importing a root CA.
--cert <certfile>	Name of the certificate file.
--privkey <key_file>	Name of the private key file. This file must be in PEM encoded format.
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.

Example:

```
certool --rootca --cert=root.cert --privkey=privatekey.pem
```

certool --getdc

Returns the default domain name that is used by vmdir.

Option	Description
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.
--port <port_num>	Optional port number. Defaults to port 389.

Example:

```
certool --getdc
```

certool --waitVMDIR

Wait until the VMware Directory Service is running or until the timeout specified by --wait has elapsed. Use this option along with other options to schedule certain tasks, for example returning the default domain name.

Option	Description
--wait	Optional number of minutes to wait. Defaults to 3.
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.
--port <port_num>	Optional port number. Defaults to port 389.

Example:

```
certool --waitVMDIR --wait 5
```

certool --waitVMCA

Wait until the VMCA service is running or until the specified timeout has elapsed. Use this option in conjunction with other options to schedule certain tasks, for example, generating a certificate.

Option	Description
--wait	Optional number of minutes to wait. Defaults to 3.
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.
--port <port_num>	Optional port number. Defaults to port 389.

Example:

```
certool --waitVMCA --selfca
```

certool --publish-roots

Forces an update of root certificates. This command requires administrative privileges.

Option	Description
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.

Example:

```
certool --publish-roots
```

certool Management Commands Reference

The `certool` management commands allow you to view, generate, and revoke certificates and to view information about certificates.

certool --genkey

Generates a private and public key pair. Those files can then be used to generate a certificate that is signed by VMCA.

Option	Description
--genkey	Required for generating a private and public key.
--privkey <keyfile>	Name of the private key file.
--pubkey <keyfile>	Name of the public key file.
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.

Example:

```
certool --genkey --privkey=<filename> --pubkey=<filename>
```

certool --gencert

Generates a certificate from the VMCA server. This command uses the information in `certool.cfg` or in the specified configuration file. You can use the certificate to provision machine certificates or solution user certificates.

Option	Description
--gencert	Required for generating a certificate.
--cert <certfile>	Name of the certificate file. This file must be in PEM encoded format.
--privkey <keyfile>	Name of the private key file. This file must be in PEM encoded format.
--config <config_file>	Name of the configuration file. A sample configuration file is located at `/usr/lib/vmware-vmca/share/config/certool.cfg`. As a best practice, make a copy of the default configuration file and replace the required fields.
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.

Example:

```
certool --gencert --privkey=<filename> --cert=<filename> --config=<config_file>
```

certool --getrootca

Prints the current root CA certificate in human-readable form. This output is not usable as a certificate, it is changed to be human readable.

Option	Description
--getrootca	Required for printing the root certificate.
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.

Example:

```
certool --getrootca --server=remoteserver
```

certool --viewcert

Print all the fields in a certificate in human-readable form.

Option	Description
--viewcert	Required for viewing a certificate.
--cert <certfile>	Name of the configuration file. A sample configuration file is located at `/usr/lib/vmware-vmca/share/config/certool.cfg`. As a best practice, make a copy of the default configuration file and replace the required fields.

Example:

```
certool --viewcert --cert=<filename>
```

certool --enumcert

List all certificates that the VMCA server knows about. The required filter option lets you list all certificates or only revoked, active, or expired certificates.

Option	Description
--enumcert	Required for listing all certificates.
--filter [all | active]	Required filter. Specify all or active. The revoked and expired options are not currently supported.

Example:

```
certool --enumcert --filter=active
```

certool --status

Sends a specified certificate to the VMCA server to check whether the certificate has been revoked. Prints `Certificate: REVOKED` if the certificate is revoked, and `Certificate: ACTIVE` otherwise.

Option	Description
--status	Required to check the status of a certificate.
--cert <certfile>	Name of the configuration file. A sample configuration file is located at `/usr/lib/vmware-vmca/share/config/certool.cfg`. As a best practice, make a copy of the default configuration file and replace the required fields.
--server <server>	Optional name of the VMCA server. By default, the command uses localhost.

Example:

```
certool --status --cert=<filename>
```

certool --genselfcacert

Generates a self-signed certificate based on the values in the configuration file. This command generates a certificate that is predated by three days to avoid time zone conflicts.

Option	Description
--genselfcacert	Required for generating a self-signed certificate.
--outcert <cert_file>	Name of the certificate file. This file must be in PEM encoded format.
--outprivkey <key_file>	Name of the private key file. This file must be in PEM encoded format.
--config <config_file>	Name of the configuration file. A sample configuration file is located at `/usr/lib/vmware-vmca/share/config/certool.cfg`. As a best practice, make a copy of the default configuration file and replace the required fields.

Example:

```
certool --genselfcert --privkey=<filename> --cert=<filename> --config=<config_file>
```

vecs-cli Command Reference

The `vecs-cli` command set allows you to manage instances of VMware Certificate Store (VECS). Use these commands together with `dir-cli` and `certool` to manage your certificate infrastructure and authentication services.

vecs-cli store create

Creates a certificate store.

Option	Description
--name <name>	Name of the certificate store.
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.

Example:

```
vecs-cli store create --name <store>
```

vecs-cli store delete

Deletes a certificate store. You cannot delete the MACHINE_SSL_CERT, TRUSTED_ROOTS and TRUSTED_ROOT_CRLS system stores. Users with required privileges can delete solution user stores.

Option	Description
--name <name>	Name of the certificate store to delete.
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.

Example:

```
vecs-cli store delete --name <store>
```

vecs-cli store list

List certificate stores.

Option	Description
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.

VECS includes the following stores.

Table 86: Stores in VECS

Store	Description
Machine SSL store (MACHINE_SSL_CERT)	• Used by the reverse proxy service on every vSphere node. • Used by the VMware Directory Service (vmdir) on each vCenter node. All services in vSphere 6.0 and later communicate through a reverse proxy, which uses the machine SSL certificate. For backward compatibility, the 5.x services still use specific ports. As a result, some services such as vpxd still have their own port open.
Solution user stores • `machine` • `vpxd` • `vpxd-extension` • `vsphere-webclient` • `wcp`	VECS includes one store for each solution user. The subject of each solution user certificate must be unique, for example, the machine certificate cannot have the same subject as the vpxd certificate. Solution user certificates are used for authentication with vCenter Single Sign-On. vCenter Single Sign-On checks that the certificate is valid, but does not check other certificate attributes. The following solution user certificate stores are included in VECS: • `machine`: Used by the license server and the logging service. **Note:** The machine solution user certificate has nothing to do with the machine SSL certificate. The machine solution user certificate is used for the SAML token exchange. The machine SSL certificate is used for secure SSL connections for a machine. • `vpxd`: vCenter service daemon (vpxd) store. vpxd uses the solution user certificate that is stored in this store to authenticate to vCenter Single Sign-On. • `vpxd-extension`: vCenter extensions store. Includes the Auto Deploy service, inventory service, and other services that are not part of other solution users. • `vsphere-webclient`: vSphere Client store. Also includes some additional services such as the performance chart service. • `wcp`: VMware vSphere® with VMware Tanzu™ store. Also used for vSphere Cluster Services. Each vCenter node includes a `machine` certificate.
Trusted root store (TRUSTED_ROOTS)	Contains all trusted root certificates.
vSphere Certificate Manager Utility backup store (BACKUP_STORE)	Used by VMCA (VMware Certificate Manager) to support certificate revert. Only the most recent state is stored as a backup, you cannot go back more than one step.

Store	Description
Other stores	Other stores might be added by solutions. For example, the Virtual Volumes solution adds an SMS store. Do not modify the certificates in those stores unless Broadcom documentation or a Broadcom Knowledge Base article instructs you to do so. **Note:** Deleting the TRUSTED_ROOTS_CRLS store can damage your certificate infrastructure. Do not delete or modify the TRUSTED_ROOTS_CRLS store.

Example:

```
vecs-cli store list
```

vecs-cli store permissions

Grants or revokes permissions to the store. Use either the --grant or the --revoke option.

The owner of the store can perform all operations, including granting and revoking permissions. The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default, has all privileges on all stores, including granting and revoking permissions.

You can use `vecs-cli get-permissions --name <store-name>` to retrieve the current settings for the store.

Option	Description
--name <name>	Name of the certificate store.
--user <username>	Unique name of the user who is granted permissions.
--grant [read|write]	Permission to grant, either read or write.
--revoke [read|write]	Permission to revoke, either read or write. Not currently supported.

vecs-cli store get-permissions

Retrieves the current permission settings for the store.

Option	Description
--name <name>	Name of the certificate store.
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.

vecs-cli entry create

Creates an entry in VECS. Use this command to add a private key or certificate to a store.

Note:
Do not use this command to add root certificates to the TRUSTED_ROOTS store. Instead, use the `dir-cli` command to publish root certificates.

Option	Description
--store <NameOfStore>	Name of the certificate store.
--alias <Alias>	Optional alias for the certificate. This option is ignored for the trusted root store.
--cert <certificate_file_path>	Full path of the certificate file.

Option	Description
--key <key-file-path>	Full path of the key that corresponds to the certificate. Optional.
--password <password>	Optional password for encrypting the private key.
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.

vecs-cli entry list

Lists all entries in a specified store.

Option	Description
--store <NameOfStore>	Name of the certificate store.

vecs-cli entry getcert

Retrieves a certificate from VECS. You can send the certificate to an output file or display it as human-readable text.

Option	Description
--store <NameOfStore>	Name of the certificate store.
--alias <Alias>	Alias of the certificate.
--output <output_file_path>	File to write the certificate to.
--text	Displays a human-readable version of the certificate.
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.

vecs-cli entry getkey

Retrieves a key that is stored in VECS. You can send the key to an output file or display it as human-readable text.

Option	Description
--store <NameOfStore>	Name of the certificate store.
--alias <Alias>	Alias for the key.
--output <output_file_path>	Output file to write the key to.
--text	Displays a human-readable version of the key.
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.

vecs-cli entry delete

Deletes an entry in a certificate store. If you delete an entry in VECS, you permanently remove it from VECS. The only exception is the current root certificate. VECS polls vmdir for a root certificate.

Option	Description
--store <NameOfStore>	Name of the certificate store.
--alias <Alias>	Alias for the entry you want to delete.
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.
-y	Suppresses the confirmation prompt. For advanced users only.

vecs-cli force-refresh

Forces a refresh of VECS. By default, VECS polls vmdir for new root certificate files every 5 minutes. Use this command for an immediate update of VECS from vmdir.

Option	Description
--server <server-name>	Used to specify a server name if you connect to a remote VECS instance.
--upn <user-name>	User Principle Name that is used to log in to the server instance specified by --server <server-name> . When you create a store, it is created in the context of the current user. Therefore, the owner of the store is the current user context and not always the root user.

dir-cli Command Reference

The `dir-cli` utility supports creation and updates to solution users, account management, and management of certificates and passwords in VMware Directory Service (vmdir). You can use `dir-cli` to manage and query the domain functional level of vCenter instances.

dir-cli nodes list

Lists all the enhanced linked mode connected vCenter systems.

Option	Description
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.
--server <psc_ip_or_fqdn>	Use this option to connect to another vCenter to see its replication partners.

dir-cli computer password-reset

Enables you to reset the password of the machine account in the domain.

Option	Description
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.
--live-dc-hostname <server name>	Current name of the vCenter instance.

dir-cli service create

Creates a solution user. Primarily used by third-party solutions.

Option	Description
--name <name>	Name of the solution user to create
--cert <cert file>	Path to the certificate file. This can be a certificate signed by VMCA or a third-party certificate.
--ssogroups <comma-separated-groupnames>	Makes the solution user a member of the specified groups.
--wstrustrole <ActAsUser>	Makes the solution user a member of the built-in administrators or users group. In other words, determines whether the solution user has administrative privileges.
--ssoadminrole <Administrator/User>	Makes the solution user a member of the ActAsUser group. The ActAsUser role enables users to act on behalf of other users.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli service list

List the solution users that `dir-cli` knows about.

Option	Description
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli svaccount list

List the service account users that `dir-cli` knows about.

Option	Description
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli service delete

Delete a solution user in vmdir. When you delete the solution user, all associated services become unavailable to all management nodes that use this instance of vmdir.

Option	Description
--name	Name of the solution user to delete.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli service update

Updates the certificate for a specified solution user, that is, collection of services. After running this command, update the solution user certificate entry in VECS by running the `vecs-cli entry create` command. See vecs-cli Command Reference.

Option	Description
--name <name>	Name of the solution user to update .
--cert <cert_file>	Name of the certificate to assign to the service.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli user create

Creates a regular user inside vmdir. This command can be used for human users who authenticate to vCenter Single Sign-On with a user name and password. Use this command only during prototyping.

Option	Description
--account <name>	Name of the vCenter Single Sign-On user to create.
--user-password <password>	Initial password for the user.
--first-name <name>	First name for the user.
--last-name <name>	Last name for the user.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli user modify

Modifies the specified user inside vmdir.

Option	Description
--account <name>	Name of the vCenter Single Sign-On user to modify.
--password-never-expires	Set this option to true if you are modifying a user account for automated tasks that have to authenticate to vCenter, and you want to ensure that the tasks do not stop running because of password expiration. Use this option with care.
--password-expires	Set this option to true if you want to revert the --password-never-expires option.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli user delete

Deletes the specified user inside vmdir.

Option	Description
--account <name>	Name of the vCenter Single Sign-On user to delete.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli user find-by-name

Finds a user inside vmdir by name. The information that this command returns depends on what you specify in the `--level` option.

Option	Description
--account <name>	Name of the vCenter Single Sign-On user to find.
--level <info level 0|1|2>	Returns the following information: • Level 0 - Account and UPN • Level 1 - level 0 info + First and last name • Level 2 : level 0 + Account deactivated flag, Account locked flag, Password never expires flag, password expired flag and password expiry flag. The default level is 0.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli group modify

Adds a user or group to an existing group.

Option	Description
--name <name>	Name of the group in vmdir.
--add <user_or_group_name>	Name of the user or group to add.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli group list

Lists a specified vmdir group.

Option	Description
--name <name>	Optional name of the group in vmdir. This option allows you to check whether a specific group exists.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli ssogroup create

Create a group inside the local domain (vsphere.local by default).

Use this command if you want to create groups to manage user permissions for the vCenter Single Sign-On domain. For example, if you create a group and then add it to the Administrators group of the vCenter Single Sign-On domain, then all users that you add to that group have administrator permissions for the domain.

It is also possible to give permissions to vCenter inventory objects to groups in the vCenter Single Sign-On domain. See the *vSphere Security* documentation.

Option	Description
--name <name>	Name of the group in vmdir. Maximum length is 487 characters.
--description <description>	Optional description for the group.

Option	Description
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli trustedcert publish

Publishes a trusted root certificate to vmdir. After running this command, VECS picks up the certificate change after one minute, or you can run the `vecs-cli force-refresh` command to sync the certificate immediately.

Note:

Starting in vSphere 8.0 Update 3, use either the vSphere Client or the API to publish a trusted root certificate and avoid having to restart services.

Option	Description
--cert <file>	Path to certificate file.
--crl <file>	This option is not supported by VMCA.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.
--chain	Specify this option if you are publishing a chained certificate. No option value is needed.

dir-cli trustedcert unpublish

Unpublishes a trusted root certificate currently in vmdir. Use this command, for example, if you added a different root certificate to vmdir that is now the root certificate for all other certificates in your environment. Unpublishing certificates that are no longer in use is part of hardening your environment.

Note:

Starting in vSphere 8.0 Update 3, use the API to unpublish a trusted root certificate and avoid having to restart services.

Option	Description
--cert <file>	Path to the certificate file to unpublish
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli trustedcert list

Lists all trusted root certificates and their corresponding IDs. You need the certificate IDs to retrieve a certificate with `dir-cli trustedcert get`.

Option	Description
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli trustedcert get

Retrieves a trusted root certificate from vmdir and writes it to a specified file.

Option	Description
--id <cert_ID>	ID of the certificate to retrieve. The `dir-cli trustedcert list` command shows the ID.
--outcert <path>	Path to write the certificate file to.
--outcrl <path>	Path to write the CRL file to. Not currently used.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli password create

Creates a random password that meets the password requirements. This command can be used by third-party solution users.

Option	Description
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli password reset

Allows an administrator to reset a user's password. If you are a non-administrator user who wants to reset a password, use `dir-cli password change` instead.

Option	Description
--account	Name of the account to assign a new password to.
--new	New password for the specified user.
--login <admin_user_id>	The administrator of the local vCenter Single Sign-On domain, administrator@vsphere.local by default.
--password <admin_password>	Password of the administrator user. If you do not specify the password, you are prompted.

dir-cli password change

Allows a user to change their password. You must be the user who owns the account to make this change. Administrators can use `dir-cli password reset` to reset any password.

Option	Description
--account	Account name.
--current	Current password of the user who owns the account.
--new	New password of the user who owns the account.

vSphere Authentication with vCenter Single Sign-On

vCenter Single Sign-On is an authentication broker and security token exchange infrastructure. vCenter Single Sign-On issues a token when a user authenticates. The user can use the token to authenticate to vCenter services. The user can then perform the actions that user has privileges for.

Because traffic is encrypted for all communications, and because only authenticated users can perform the actions that they have privileges for, your environment is secure.

Users and service accounts authenticate with a token, or a user name and password. Solution users authenticate with a certificate. For information on replacing solution user certificates, see vSphere Security Certificates. For information about replacing solution user certificates, see vSphere Security Certificates.

The next step is authorizing the users who can authenticate to perform certain tasks. Usually, you assign vCenter privileges, typically by assigning the user to a group that has a role. vSphere includes other permission models such as global permissions. See the *vSphere Security* documentation.

How vCenter Single Sign-On Protects Your Environment

vCenter Single Sign-On allows vSphere components to communicate with each other through a secure token mechanism.

vCenter Single Sign-On uses the following services.

- Authentication of users through either external identity provider federation or the vCenter built-in identity provider. The built-in identity provider supports local accounts, Active Directory or OpenLDAP, and miscellaneous authentication mechanisms.
- Authentication of solution users through certificates.
- Security Token Service (STS).
- SSL for secure traffic.

vCenter Built-in Identity Provider

vCenter includes a built-in identity provider. By default, vCenter uses the vsphere.local domain as the identity source (but you can change the domain during installation). You can configure the vCenter built-in identity provider to use Active Directory (AD) as its identity source using LDAP/S, or OpenLDAP/S. Such configurations allow customers to log in to vCenter using their AD accounts.

vCenter and an External Identity Provider

In vSphere 9.0 and later, external identity provider federation is the preferred authentication method for vCenter.

vSphere supports the following identity providers.

- vSphere 7.0 and later: Active Directory Federation Services (AD FS)
- vSphere 8.0 Update 1 and later: Okta
- vSphere 8.0 Update 2 and later: Microsoft Entra ID (formerly called Azure AD)
- Starting in vSphere 8.0 Update 3: PingFederate

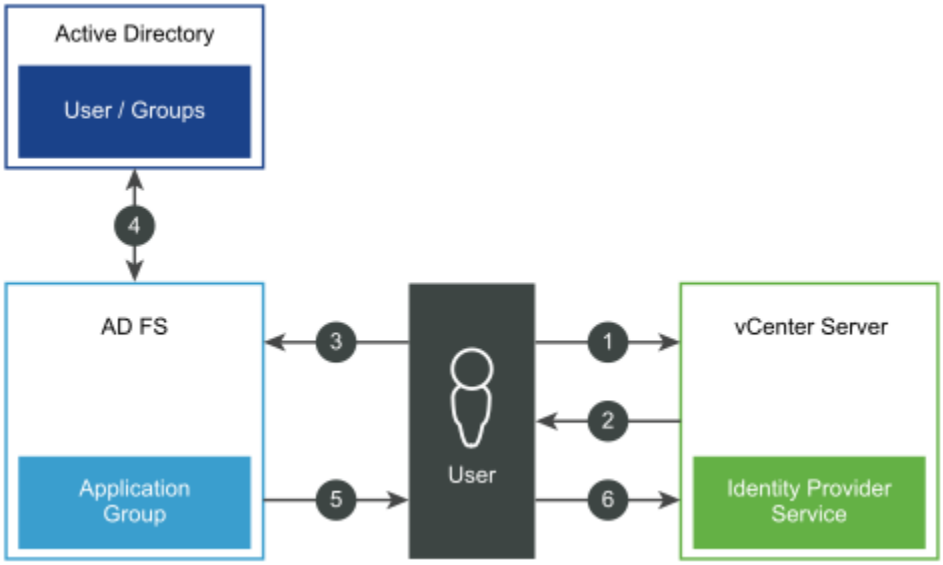
When you configure vSphere to use an external identity provider, the external identity provider interacts with the identity sources on behalf of vCenter.

User Login with vCenter Identity Provider Federated Authentication

When you use an external identity provider to authenticate with vCenter, vCenter redirects the login request to the external identity provider. The external identity provider authenticates the user with its directory service then issues a token for vCenter to use to log in the user.

For example, the following figure shows a detailed look at the user login flow for vCenter Identity Provider Federation using AD FS.

Figure 30: vCenter User Login Using AD FS Identity Provider Federation



vCenter, AD FS, and Active Directory interact as follows:

1. The user starts on the vCenter landing page by entering a user name.
2. If the user name is for a federated domain, vCenter redirects the authentication request to AD FS.
3. If needed, AD FS prompts the user to log in with Active Directory credentials.
4. AD FS authenticates the user with Active Directory.
5. AD FS issues a security token with group information from Active Directory.
6. vCenter uses the token to log in the user.

The user is now authenticated, and can view and modify any objects that the user's role has privileges for.

> **Note:**
> Initially, each user is assigned the No Access role. A vCenter administrator must assign the user at least to the Read Only role before the user can log in. See the *vSphere Security* documentation.

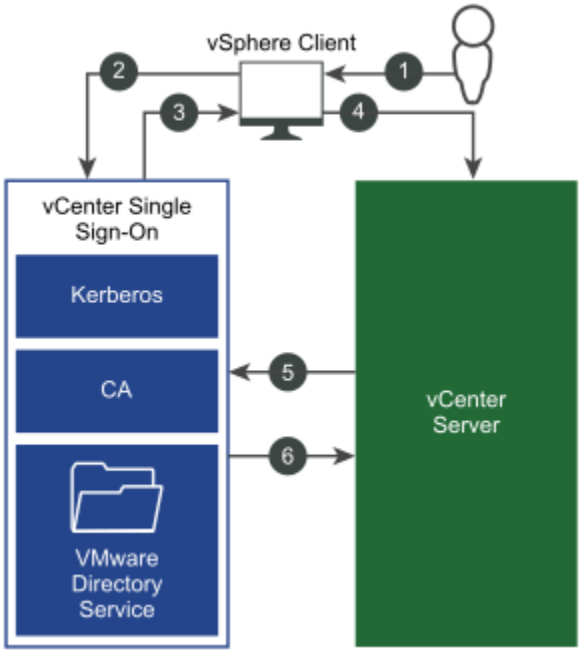
In case the external identity provider is unreachable, the login process falls back to the vCenter landing page, showing an appropriate information message. Users can still log in using their local accounts in the vsphere.local identity source.

The interaction between vCenter and Okta, Microsoft Entra ID, or PingFederate is similar to that of AD FS, with the exception that vCenter uses VMware Identity Services. See VMware Identity Services Authentication Process.

User Login with the vCenter Built-In Identity Provider

The following figure shows the user login flow when vCenter acts as the identity provider.

Figure 31: User Login with the vCenter Built-In Identity Provider



1. A user logs in to the vSphere Client with a user name and password to access the vCenter system or another vCenter service.
2. The vSphere Client passes the login information to the vCenter Single Sign-On service, which checks the SAML token of the vSphere Client. If the vSphere Client has a valid token, vCenter Single Sign-On then checks whether the user is in the configured identity source (for example, Active Directory).
   - If only the user name is used, vCenter Single Sign-On checks in the default domain.
   - If a domain name is included with the user name (*DOMAIN*\user1 or user1@*DOMAIN*), vCenter Single Sign-On checks that domain.
3. If the user can authenticate to the identity source, vCenter Single Sign-On returns a token that represents the user to the vSphere Client.
4. The vSphere Client passes the token to the vCenter system.
5. vCenter checks with the vCenter Single Sign-On server that the token is valid and not expired.
6. The vCenter Single Sign-On server returns the token to the vCenter system, using the vCenter Authorization Framework to allow user access.

The user is now authenticated, and can view and modify any objects that the user's role has privileges for.

> **Note:**
> Initially, each user is assigned the No Access role. A vCenter administrator must assign the user at least to the Read Only role before the user can log in. See the *vSphere Security* documentation.

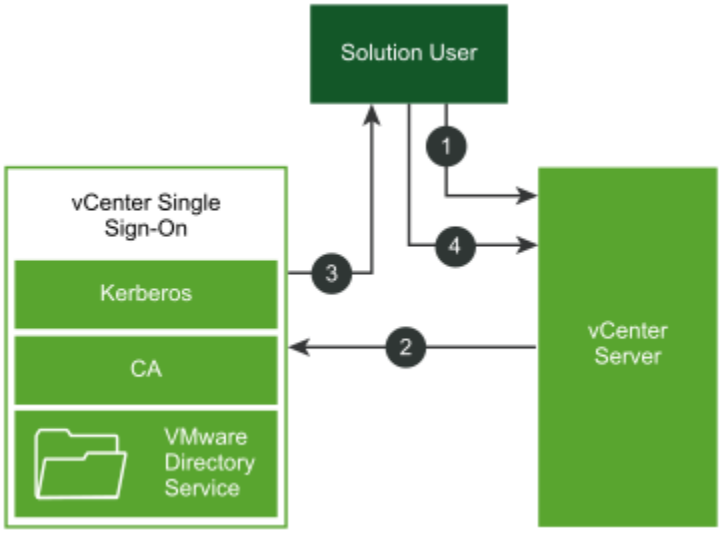
Login for Solution Users

Solution users are sets of services that are used in the vCenter infrastructure, for example, vCenter extensions. VMware extensions and potentially third-party extensions might also authenticate to vCenter Single Sign-On.

> **Note:**
> vCenter uses solution user certificates for internal communication only. Solution user certificates are not used for external communication.

The following figure shows the login flow for solution users.

Figure 32: Login for Solution Users



1. The solution user attempts to connect to a vCenter service.
2. The solution user is redirected to vCenter Single Sign-On. If the solution user is new to vCenter Single Sign-On, it has to present a valid certificate.
3. If the certificate is valid, vCenter Single Sign-On assigns a SAML token (bearer token) to the solution user. The token is signed by vCenter Single Sign-On.
4. The solution user is then redirected to vCenter Single Sign-On and can perform tasks based on its permissions. The next time the solution user has to authenticate, it can use the SAML token to log in to vCenter.

By default, this handshake is automatic because VMCA provisions solution users with certificates during startup. If your company policy requires third-party CA-signed certificates, you can replace the solution user certificates with third-party CA-signed certificates. If those certificates are valid, vCenter Single Sign-On assigns a SAML token to the solution user. See Replace Solution User Certificates with Custom Certificates Using the Certificate Manager.

Supported Encryption in vSphere

AES encryption, which is the highest level of encryption, is supported. The supported encryption affects security when vCenter Single Sign-On uses Active Directory as an identity source.

It also affects security anytime an ESX host or vCenter is joined to Active Directory.

vCenter Identity Provider Federation

In vSphere 9.0 and later, external identity provider federation is the preferred authentication method for vCenter.

To enable federated authentication to vCenter, you configure a connection to an external identity provider. The identity provider instance that you configure replaces vCenter as the identity provider. Currently, vCenter supports Active Directory Federation Services (AD FS), Okta, Microsoft Entra ID (formerly called Azure AD), and PingFederate as external identity providers. vCenter supports AD FS in vSphere 7.0 and later, Okta in vSphere 8.0 Update 1 and later, Microsoft Entra ID in vSphere 8.0 Update 2 and later, and PingFederate starting in vSphere 8.0 Update 3.

> **Note:**
> VMware encourages you to use federated authentication as vSphere moves towards token-based authentication. vCenter continues to have local accounts, for administrative access and error recovery.

How vCenter Identity Provider Federation Works

vCenter Identity Provider Federation enables you to configure an external identity provider for federated authentication. In this configuration, the external identity provider interacts with the identity source on behalf of vCenter. In vSphere 9.0 and later, external identity provider federation is the preferred authentication method for vCenter. With VCF 9.0 we are moving

towards a modern authentication which leverages federation of vCenter with an external IDP provider. Native vCenter features for multi-factor authentication is deprecated in favor of leveraging the external identity providers capabilities or multi-factor authentication. For more information on VCF single sign on, see VCF Single Sign-On.

vCenter Identity Provider Federation Basics

The vCenter authentication will transparently delegate the authentication call to the federated IDP which performs the authentication by all supported means including multi-factor authentication, and then return a token to VC which is used for authentication. All multi-factor authentication options including the token validity time can be configured at the external identity provider settings.

vCenter External Identity Provider Support

vCenter supports the following external identity providers:

- **ADFS** (vSphere 7.0 and later)
- **OKTA** (vSphere 8.0 Update 1 and later)
- **Microsoft Entra ID**, formerly called Azure AD (vSphere 8.0 Update 2 and later)
- **PingFederate** (starting in vSphere 8.0 Update 3)

Consider the version and timelines when you plan your migration to a federated VC authentication.

vCenter Identity Provider Federation Benefits

vCenter Identity Provider Federation provides the following benefits.

- You can use Single Sign-On with existing federated infrastructure and applications.
- You can improve data center security because vCenter never handles the user's credentials.
- You can use the authentication mechanisms, such as multi-factor authentication, supported by the external identity provider.

vCenter Identity Provider Federation Architecture

To establish a relying party trust between vCenter and an external identity provider, you must establish the identifying information and a shared secret between them. vCenter uses the OpenID Connect (OIDC) protocol to receive an identity token that authenticates the user with vCenter.

The high-level steps to configure an external identity provider with vCenter include:

1. Establishing a relying party trust between vCenter and the external identity provider by creating an OIDC configuration. For AD FS, you create an Application Group, or Application. For Okta, Microsoft Entra ID, and PingFederate, you create a native application with OpenID Connect as the sign-on method. The OIDC configuration consists of a Server application and a Web API. The two components specify the information that vCenter uses to trust and communicate with the external identity provider.
2. Creating a corresponding identity provider in vCenter.
3. Configuring group memberships in vCenter to authorize logins from users in the external identity provider domain.

The identity provider administrator must provide the following information to create the vCenter identity provider configuration:

- Client Identifier: The UUID string that is generated in AD FS when you create the Application Group (or Application) and that identifies the Application Group (or Application), or that is generated in Okta, Microsoft Entra ID, or PingFederate when you create the OpenID Connect application.
- Shared Secret: The secret that is generated in AD FS when you create the Application Group (or Application), or that is generated in Okta, Microsoft Entra ID, or PingFederate when you create the OpenID Connect application, and that is used to authenticate vCenter with the external identity provider.
- OpenID Address: The OpenID Provider Discovery endpoint URL of the external identity provider server, specifying a well-known address that is typically the issuer endpoint concatenated with the path `/.well-known/openid-configuration`. Here is an example OpenID address for an AD FS configuration:

  ```
  https://webserver.example.com/adfs/.well-known/openid-configuration
  ```

Likewise, here is an example OpenID address for an Okta configuration:

```
https://example.okta.com/oauth2/default/.well-known/openid-configuration
```

Here is an example OpenID address for a Microsoft Entra ID configuration:

```
https://login.microsoftonline.com/11111111-2222-3333-4444-555555555555/v2.0/.well-known/openid-configuration
```

Here is an example OpenID address for a PingFederate configuration:

```
https://pingfederate-fqdn-and-port/.well-known/openid-configuration
```

VMware Identity Services and Federated Authentication

In vSphere 8.0 Update 1 and later, VMware Identity Services provides integration with external identity providers as a federated identity provider. You can think of the VMware Identity Services as a "slimmed" down version of VMware Workspace ONE that is built-in to vSphere.

When you either install or upgrade to vSphere 8.0 Update 1 or later, VMware Identity Services are activated by default on vCenter. When you configure Okta, Microsoft Entra ID, or PingFederate as an external identity provider, vCenter uses VMware Identity Services to communicate with your Okta, Microsoft Entra ID, or PingFederate server.

vCenter supports Okta, Microsoft Entra ID, and PingFederate as an external identity provider in an Enhanced Linked Mode configuration. Even though, in an Enhanced Linked Mode configuration, multiple vCenter systems are running VMware Identity Services, only a single vCenter and, its VMware Identity Services communicate with your external identity provider server. For example, if you have an Enhanced Linked Mode configuration of three vCenter systems, A, B, and C, and you configure the Okta external identity provider on vCenter A, vCenter A is the only system to handle all the Okta logins. vCenter B and vCenter C do not directly communicate with the Okta server. To configure VMware Identity Services on other vCenter in the ELM configuration to interact with your external IDP server, see Activation Process for External Identity Providers in Enhanced Linked Mode Configurations.

Note:

When federated, vCenter supports only a single federation provider. No other external identity sources such as AD-over-LDAP are supported while vCenter is federated.

Note:
When configuring Okta as an external identity provider, all the vCenter systems in an Enhanced Linked Mode configuration must run at least vSphere 8.0 Update 1. For Microsoft Entra ID, the requirement is at least vSphere 8.0 Update 2. For PingFederate the requirement is at least vSphere 8.0 Update 3.

Warning:
When using an Enhanced Linked Mode configuration with Okta, Microsoft Entra ID, or PingFederate, you cannot remove the vCenter that runs the VMware Identity Services and that communicates with the identity provider from the ELM configuration.

VMware Identity Services Authentication Process

When you configure vCenter to use VMware Identity Services to communicate with your external identity provider, the following authentication process occurs:

1. A user logs in to vCenter with the vSphere Client.
2. vCenter Single Sign-On delegates the user authentication and redirects the user request to VMware Identity Services.
3. The VMware Identity Services process requests a token from the external identity provider to establish the user session.
4. The external identity provider authenticates the user (it can use Multifactor Authentication (MFA) or SSO credentials) and returns the token to VMware Identity Services.
   The token contains the user claims.
5. The VMware Identity Services process validates the identity provider token, generates a corresponding VMware Identity Services token, and sends the VMware Identity Services token to vCenter Single Sign-On.
6. vCenter Single Sign-On validates the token and grants the login request.

Note:
AD FS does not use VMware Identity Services for federated authentication.

How vCenter Interacts with Users and Groups Pushed by SCIM

When you configure your external identity provider, vCenter uses System for Cross-domain Identity Management (SCIM) for user and group management. SCIM is an open standard for automating the exchange of user identity information. A SCIM application that you create on your external IDP server manages the users and groups on external identity provider that you want to push to vCenter. vCenter also uses SCIM when searching for users and groups to assign permissions to vCenter objects.

Note:
An AD FS configuration searches the Active Directory by using LDAP. It does not use SCIM.

vCenter Identity Provider Federation Components

The following components comprise a vCenter Identity Provider Federation configuration:

- A vCenter
  - For AD FS: vCenter 7.0 or later
  - For Okta: vCenter 8.0 Update 1 or later
  - For Microsoft Entra ID: vCenter 8.0 Update 2 or later
  - For PingFederate: vCenter 8.0 Update 3
- An identity provider service configured on the vCenter
- An external identity provider (AD FS, Okta, Microsoft Entra ID, or PingFederate)
- An OpenID Connect (OIDC) configuration:
  - For AD FS: An Application Group (also called an Application)
  - For Okta, Microsoft Entra ID, or PingFederate: An OpenID Connect application
- A System for Cross-domain Identity Management (SCIM) application for user and group management (only for Okta, Microsoft Entra ID, or PingFederate)
- External identity provider groups and users that you map to vCenter groups and users
- VMware Identity Services enabled on vCenter (only for Okta, Microsoft Entra ID, or PingFederate)
- Optionally, for PingFederate, the SSL certificate, or certificate chain, of the PingFederate server, if this certificate was not issued by a well-known, public Certificate Authority. You import the PingFederate SSL certificate to the vCenter.

vCenter Identity Provider Federation Caveats and Interoperability

vCenter Identity Provider Federation can inter-operate with many other VMware features.

As you are planning your vCenter Identity Provider Federation strategy, consider possible interoperability limitations.

Authentication Mechanisms

In a vCenter Identity Provider Federation configuration, the external identity provider handles the authentication mechanisms (passwords, MFA, biometrics, and so on).

AD FS and Support for a Single Active Directory Domain

When you configure vCenter Identity Provider Federation for AD FS, the Configure Main Identity Provider wizard prompts you to enter LDAP information for the single AD domain that contains the users and groups you want to access vCenter. vCenter derives the AD domain to use for authorization and permissions from the User Base DN that you specify in the wizard. You can add permissions on vSphere objects only for users and groups from this AD domain. Users or groups from AD child domains or other domains in the AD forest are not supported by vCenter Identity Provider Federation.

Okta, Microsoft Entra ID, and PingFederate Support for Multiple Domains

When you configure vCenter Identity Provider Federation for Okta, Microsoft Entra ID, or PingFederate, the Configure Main Identity Provider wizard enables you to enter LDAP information for the multiple domains that contain the users and groups you want to access vCenter.

Password, Lockout, and Token Policies

When vCenter acts as the identity provider, you control vCenter password, lockout, and token policies for the default domain (vsphere.local, or the domain name you entered when installing vSphere). When using federated authentication with vCenter, the external identity provider controls the password, lockout, and token policies for the accounts stored in the identity source such as Active Directory.

Auditing and Compliance

When using vCenter Identity Provider Federation, vCenter continues to create log entries for successful user logins. However, the external identity provider is responsible for tracking and logging actions such as failed password-entry attempts and user account lockouts. vCenter does not log such events because they are no longer visible to vCenter. For example, when AD FS is the identity provider, AD FS tracks and logs errors for federated logins. When vCenter is the identify provider for local logins, vCenter tracks and logs errors for local logins. In a federated configuration, vCenter does continue to log user actions post-login.

Existing VMware Product Integration with External Identity Providers

VMware products that are integrated with vCenter (for example, VMware Cloud Foundation Operations (formerly Aria Operations), vSAN, NSX, and so on) continue to work as before.

Products That Integrate Post-Login

Products that integrate post-login (that is, they do not require a separate login) continue to work as before.

Simple Authentication for API, SDK, and CLI Access

Existing scripts, products, and other functionality that rely on API, SDK, or CLI commands that use Simple Authentication (that is, user name and password) continue to work as before. Internally, the authentication occurs by passing the user name and password. This passing of the user name and password compromises some of the benefits of using identity federation, because it exposes the password to vCenter (and your scripts). Consider migrating to token-based authentication where possible.

Accessing the vCenter Management Interface

If the user is a member of the vCenter Administrators group, accessing the vCenter Management Interface (formerly called vCenter Appliance Management Interface or VAMI) is supported.

Entering User Name Text on the AD FS Login Page

The AD FS login page does not support passing text to pre-populate the user name text box. As a result, during federated logins with AD FS, after entering your user name on the vCenter landing page and redirecting to the AD FS login page, you must reenter your user name on the AD FS login page. The user name that you enter on the vCenter landing page is necessary to redirect the login to the appropriate identity provider, and the user name on the AD FS login page is necessary to authenticate with AD FS. This inability to pass the user name to the AD FS login page is a limitation of AD FS. You cannot configure or change this behavior directly from vCenter.

Support for IPv6 Addresses

AD FS, Microsoft Entra ID, and Ping Federate support IPv6 addresses. Okta does not support IPv6 addresses.

VMware Identity Services Single Instance Configuration

By default, when you either install or upgrade to vSphere 8.0 Update 1 or later, VMware Identity Services are enabled on vCenter. When you configure Okta, Microsoft Entra ID, or PingFederate in an Enhanced Link Mode configuration, you use VMware Identity Services on a single vCenter system. For example, if you use Okta in an Enhanced Mode Link configuration that consists of three vCenter systems, only one vCenter its instance of VMware Identity Services is used to communicate with the Okta server.

> **Warning:**
>
> In an ELM configuration that uses VMware Identity Services, if the vCenter system that communicates with the external identity provider becomes unavailable, you can configure VMware Identity Services on other vCenter in the ELM configuration to interact with your external IDP server. See Activation Process for External Identity Providers in Enhanced Linked Mode Configurations.

Reconfiguring the Primary Network Identifier

Reconfiguring the Primary Network Identifier (PNID) of the vCenter requires that you update the external identity provider configuration as follows.

- AD FS: Add the new Redirect URIs to the AD FS server.
- Okta: Reconfigure Okta. See Configure vCenter Identity Provider Federation for Okta and follow the steps to create the identity provider on vCenter.
- Microsoft Entra ID: Reconfigure Entra ID. See Configure vCenter Identity Provider Federation for Microsoft Entra ID and follow the steps to create the identity provider on vCenter.
- PingFederate: Reconfigure PingFederate. See Configure vCenter Identity Provider Federation for PingFederate and follow the steps to create the identity provider on vCenter.

vCenter Identity Provider Federation Life Cycle

When managing the life cycle of vCenter Identity Provider Federation, there are some specific considerations.

You can manage your vCenter Identity Provider Federation life cycle in the following ways.

Migrating from Using Active Directory to an External Identity Provider

If you are using Active Directory as your identity source for vCenter, migrating to using an external identity provider is straight forward. If your Active Directory groups and roles match your identity provider groups and roles, you do not need to take any additional action. When the groups and roles do not match, then you must perform some additional work. If vCenter is a domain member, consider removing it from the domain as it is not needed or used for identity federation.

Cross-Domain Repointing and Migration

vCenter Identity Provider Federation supports cross-domain repointing, that is, moving a vCenter from one vSphere SSO domain to another. The repointed vCenter receives the replicated identity provider configuration from the vCenter system, or systems, to which it was pointed.

In general, you do not need to perform any additional identity provider reconfiguration for a cross-domain repoint, unless one of the following is true.

1. The identity provider configuration of the repointed vCenter differs from the identity provider configuration of the vCenter to which it was pointed.
2. This is the first time the repointed vCenter is receiving an identity provider configuration.

In these cases, some additional work is required. For example, for AD FS, you must add the vCenter system's Redirect URIs to the corresponding Application Group on the AD FS server. For example, if vCenter 1 with AD FS Application Group A (or no AD FS configuration) is repointed to vCenter 2 with AD FS Application Group B, you must add the Redirect URIs of vCenter 1 to Application Group B.

Users and Group Synchronization and vCenter Backup and Restore

Depending on when you synchronize your users and groups with vCenter and when you back up your vCenter, if you must restore your vCenter, you might need to re-synchronize your users and groups that were pushed by SCIM.

To restore a deleted user or group, you cannot simply push the user or group from the external identity provider to vCenter. You must update the SCIM 2.0 application on the external identity provider with the missing user or group. See Restore Deleted SCIM Users and Groups.

vCenter Identity Provider Federation and Enhanced Linked Mode

When you enable Identity Provider Federation in vCenter environments using enhanced linked mode, authentication and workflows continue to work as before.

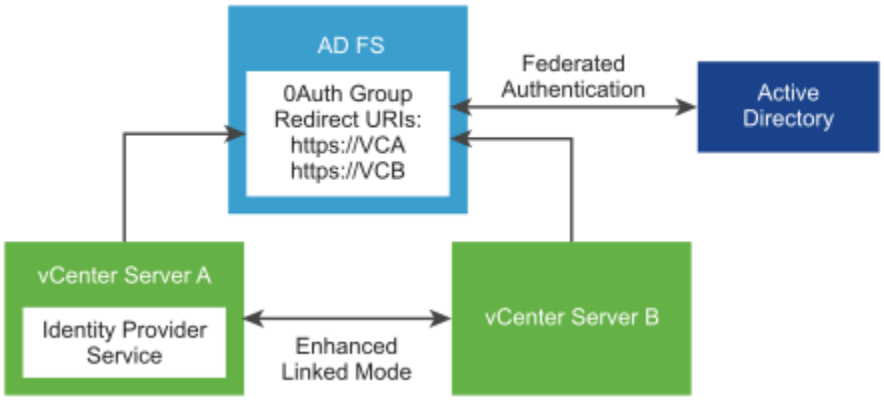
If you use Enhanced Linked Mode configuration, note the following when logging in to vCenter using federated authentication.

- Users continue to see the same inventory, and can perform the same actions, based on the vCenter permissions and roles model.
- vCenter hosts in enhanced linked mode are not required to have access to each other's identity providers. For example, consider two vCenter systems A and B, and that use enhanced linked mode. After vCenter A authorizes a user, then the user is authorized on vCenter B as well.

Enhanced Link Mode and AD FS

The following figure shows the authentication workflow when using AD FS with enhanced linked mode.

Figure 33: Enhanced Linked Mode and AD FS Identity Provider Federation



1. Two vCenter nodes are deployed in Enhanced Linked Mode configuration.
2. The AD FS setup has been configured on vCenter A using the Change Identity Provider wizard in the vSphere Client. Group memberships and permissions have also been established for AD FS users or groups.
3. vCenter A replicates the AD FS configuration to vCenter B.
4. All Redirect URIs for both vCenter nodes are added to the OAuth Application Group in AD FS. Only one OAuth Application Group is created.
5. When a user logs into and is authorized by vCenter A, the user is also authorized on vCenter B. If the user logs in to vCenter B first, the same holds true.

Enhanced Linked Mode Configuration Scenarios with AD FS

vCenter enhanced linked mode supports the following configuration scenarios for AD FS. In this section, the terms "AD FS settings" and "AD FS configuration" refer to the settings that you configure in the vSphere Client using the Change Identity Provider wizard, and any group memberships or permissions that you have established for AD FS users or groups.

Enable AD FS on an Existing Enhanced Linked Mode Configuration

High-level steps:

1. Deploy N vCenter nodes in Enhanced Linked Mode configuration.
2. Configure AD FS on one of the linked vCenter nodes.
3. The AD FS configuration is replicated to all other (N-1) vCenter nodes.
4. Add all Redirect URIs for all N vCenter nodes to the configured OAuth Application Group in AD FS.

Link a New vCenter to an Existing Enhanced Linked Mode AD FS Configuration

High-level steps:

1. (Prerequisite) Set up AD FS on a vCenter N-node Enhanced Linked Mode configuration.
2. Deploy a new independent vCenter node.
3. Repoint the new vCenter to the N-node AD FS enhanced linked mode domain, using one of the N nodes as its replication partner.
4. All AD FS settings in the existing Enhanced Linked Mode configuration are replicated to the new vCenter.
   The AD FS settings that are in the N-node AD FS enhanced linked mode domain overwrite any existing AD FS settings on the newly linked vCenter.
5. Add all Redirect URIs for the new vCenter to the existing configured OAuth Application Group in AD FS.

Unlink a vCenter from an Enhanced Linked Mode AD FS Configuration

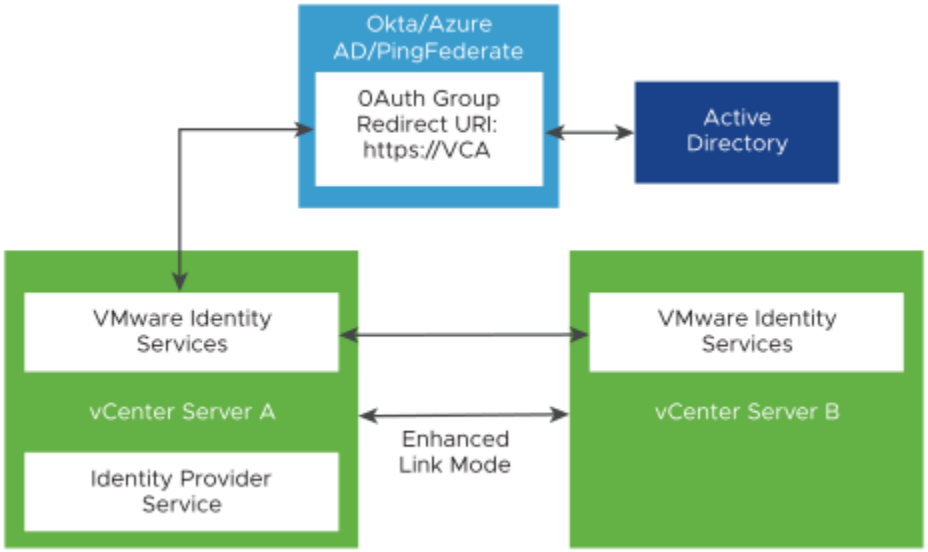
High-level steps:

1. (Prerequisite) Set up AD FS on an N-node vCenter Enhanced Linked Mode configuration.
2. Unregister one of the vCenter hosts in the N-node configuration and repoint it to a new domain to unlink it from the N-node configuration.
3. The domain repointing process does not preserve SSO settings, so all AD FS settings on the unlinked vCenter node are reverted and lost. To continue using AD FS on this vCenter unlinked node, you must reconfigure AD FS from the beginning or you must relink the vCenter to an Enhanced Linked Mode configuration where AD FS is already set up.

Enhanced Linked Mode and Okta, Microsoft Entra ID, or PingFederate Identity Provider Federation

The following figure shows the authentication workflow when using Okta, Microsoft Entra ID, or PingFederate with enhanced linked mode.

Figure 34: Enhanced Linked Mode and Okta, Microsoft Entra ID, or PingFederate Identity Provider Federation



Note:
When configuring Okta, Microsoft Entra ID, or PingFederate as an external identity provider, all the vCenter systems in an Enhanced Linked Mode configuration must run at least vSphere 8.0 Update 1 for Okta, vSphere 8.0 Update 2 for Microsoft Entra ID, and vSphere 8.0 Update 3 for PingFederate.

1. Two vCenter nodes are deployed in Enhanced Linked Mode configuration.
2. The Okta, Microsoft Entra ID, or PingFederate setup has been configured on vCenter A using the Change Identity Provider wizard in the vSphere Client. Also, group memberships and permissions have also been established for Okta, Microsoft Entra ID, or PingFederate users or groups.

   Note:
   Both vCenter A and B have VMware Identity Services enabled, but only the VMware Identity Services on vCenter A communicate with the identity provider server.
3. The VMware Identity Services running on vCenter A enable vCenter B to access its endpoint.
4. The Redirect URI for vCenter A is added to the OAuth Application in Okta, Microsoft Entra ID, or PingFederate. Only one OAuth Application is created.
5. When a user logs into and is authorized by vCenter A, the user is also authorized on vCenter B. If the user logs in to vCenter B first, the same holds true.

Enhanced Linked Mode Configuration Scenarios with Okta, Microsoft Entra ID, or PingFederate

vCenter enhanced linked mode supports the following configuration scenarios for Okta, Microsoft Entra ID, and PingFederate. In this section, the terms "Okta settings" and "Okta configuration," "Microsoft Entra ID settings" and "Microsoft Entra ID configuration," or "PingFederate settings" and "PingFederate configuration," refer to the settings that you configure in the vSphere Client using the Change Identity Provider wizard, and any group memberships or permissions that you have established for Okta, Microsoft Entra ID, or PingFederate users or groups.

Enable Okta, Microsoft Entra ID, or PingFederate on an Existing Enhanced Linked Mode Configuration

High-level steps:

1. Deploy N vCenter nodes in Enhanced Linked Mode configuration.
2. Configure Okta, Microsoft Entra ID, or PingFederate on one of the linked vCenter nodes.
3. The VMware Identity Services endpoint information is replicated to all other (N-1) vCenter nodes.
   The Okta, Microsoft Entra ID, or PingFederate configuration (shared client ID, and so on) information and user/group information is not replicated.

Link a New vCenter to an Existing Enhanced Linked Mode Okta, Microsoft Entra ID, or PingFederate Configuration

High-level steps:

1. (Prerequisite) Set up Okta, Microsoft Entra ID, or PingFederate on a vCenter N-node Enhanced Linked Mode configuration.
2. Deploy a new independent vCenter node.
3. Repoint the new vCenter to the N-node Okta, Microsoft Entra ID, or PingFederate enhanced linked mode domain, using one of the N nodes as its replication partner.
4. The VMware Identity Services endpoint information is replicated to all other (N-1) vCenter nodes.
   The Okta, Microsoft Entra ID, or PingFederate configuration (shared client ID, and so on) information and user/group information is not replicated.

   Note:
   You can add a vCenter node with an existing VMware Identity Services configuration. In this scenario, the existing VMware Identity Services configuration is replaced with the VMware Identity Services Enhanced Link Mode configuration that it is joining.

   You cannot add a vCenter node with an existing VMware Identity Services configuration to an ELM configuration that has not been configured with VMware Identity Services. In this scenario, first remove the existing VMware Identity Services configuration from the vCenter before adding it to the ELM configuration.

Unlink a vCenter from an Enhanced Linked Mode Okta, Microsoft Entra ID, or PingFederate Configuration

High-level steps:

1. (Prerequisite) Set up Okta, Microsoft Entra ID, or PingFederate on an N-node vCenter Enhanced Linked Mode configuration.
2. Unregister one of the vCenter hosts in the N-node configuration and repoint it to a new domain to unlink it from the N-node configuration.
3. The domain repointing process does not preserve SSO settings, so all Okta, Microsoft Entra ID, or PingFederate settings on the unlinked vCenter node are reverted and lost. To continue using Okta, Microsoft Entra ID, or PingFederate on this vCenter unlinked node, you must reconfigure Okta, Microsoft Entra ID, or PingFederate from the beginning or you must relink the vCenter to an Enhanced Linked Mode configuration where Okta, Microsoft Entra ID, or PingFederate is already set up.

   Note:
   You cannot unlink a vCenter with an active VMware Identity Services configuration.

Activation Process for External Identity Providers in Enhanced Linked Mode Configurations

Learn more about the availability considerations in Enhanced Linked Mode configurations with Okta, Microsoft Entra ID, or PingFederate.

- Two or more vCenter systems in an Enhanced Linked Mode configuration. For example, the systems are labeled as VC_1, VC_2, VC_3, through VC_N, where N is the number of vCenter systems in the Enhanced Linked Mode configuration.
- For Okta and Microsoft Entra ID, all vCenter systems must run vSphere 8.0 Update 2 or later. For PingFederate, all vCenter systems must run at least vSphere 8.0 Update 3.
- Okta, Microsoft Entra ID, or PingFederate is configured as an external identity provider on one of the vCenter systems. For example, the system is labeled as VC_1.
- The external identity provider is configured with all required OAuth2 and SCIM applications.

1. To activate a given vCenter VC_i where i is between 2 and N:
   a) Obtain local shell access to VC_i to run the activation script.

      Note:
      To perform the following steps, the vCenter user account with administrative privileges can be given either on the command line or in the console prompts.
   b) Execute `'status'` from the activation script to get the current activation state of the vCenter.

      ```
      python /usr/lib/vmware-trustmanagement/vmware_identity_services_activation.py status
      ```
   c) If the `'status'` command indicates that the vCenter is not activated, execute `'activate'` from the activation script:

      ```
      python /usr/lib/vmware-trustmanagement/vmware_identity_services_activation.py activate
      ```
   d) If the `'status'` command indicates that the vCenter is already activated, then execute the `'deactivate'` option then execute the `'activate'` option.

      ```
      python /usr/lib/vmware-trustmanagement/vmware_identity_services_activation.py deactivate
      ```

      - For example, execute the `'activate'` option.
      - Alternatively, you can specify the `'--force-replace'` option in the `'activate'` command.

2. Open a browser to the vCenter VC_i and log in as an administrator to vCenter.
   a) Navigate to **Home > Administration > Single Sign On > Configuration**.
   b) Under **User Provisioning**, verify that the **Tenant URL** contains the FQDN of VC_i.
   c) Copy the **Tenant URL** string and save this information for using it with the external identity provider.
   d) Under **Secret Token**, click the **Generate**, copy the generated token string, and save this information for using it with the external identity provider.
   e) Under **OpenID Connect**, verify that the **Redirect URI** contains the FQDN of VC_i.
   f) Copy the **Redirect URI** string and save this information for using it with the external identity provider.
3. Open a browser to the administration page of the external identity provider.

   Note:
   For more information, refer to the external identity provider specific details to perform the following steps.
   a) Find the OAuth2 registration that was setup when the external identity provider was originally configured in VC_1.
   b) Edit the OAuth2 registration and add the Redirect URI that was previously obtained for VC_i.
   c) If the external identity provider supports SCIM Push configurations with multiple destinations, then:
      - Find the SCIM Push configuration that was setup when the external identity provider was originally configured in VC_1.
      - Edit the SCIM Push configuration and add the **Tenant URL** and **Secret Token** that were previously obtained for VC_i.
   d) If the external identity provider supports SCIM Push configurations with only one destination:
      - Create a new SCIM Push configuration with the **Tenant URL** and **Secret Token** that were previously obtained for VC_i.
      - Ensure that the SCIM Push configuration is pushing the same user/group data as the SCIM Push configuration that was setup when the external identity provider was originally configured in VC_1.
   e) Initiate a SCIM push operation to ensure that VC_i is populated with the latest user or group data.

Configuring vCenter Identity Provider Federation

After you deploy vCenter initially, you can configure an external identity provider for federated authentication.

With VCF 9.0 we are moving towards a modern authentication which leverages federation of vCenter with an external IDP provider. Native vCenter features for multi-factor authentication is deprecated in favor of leveraging the external identity providers capabilities or multi-factor authentication.The vCenter authentication will transparently delegate the authentication call to the federated IDP which performs the authentication by all supported means including multi-factor authentication, and then return a token to VC which is used for authentication. All multi-factor authentication options including the token validity time can be configured at the external identity provider settings.

vCenter supports the following external identity providers:

- **ADFS** (vSphere 7.0 and later)
- **OKTA** (vSphere 8.0 Update 1 and later)
- **Microsoft Entra ID**, formerly called Azure AD (vSphere 8.0 Update 2 and later)
- **PingFederate** (starting in vSphere 8.0 Update 3)

You configure vCenter Identity Provider Federation from the vSphere Client or the API. You also must perform some configuration on your external identity provider. To configure vCenter Identity Provider Federation, you must have vCenter Single Sign-On administrator privileges. Having vCenter Single Sign-On administrator privileges is different from having the Administrator role on vCenter or ESX. In a new installation, only the vCenter Single Sign-On administrator (administrator@vsphere.local by default) can authenticate to vCenter Single Sign-On.

vCenter Identity Provider Federation Configuration Process Flow

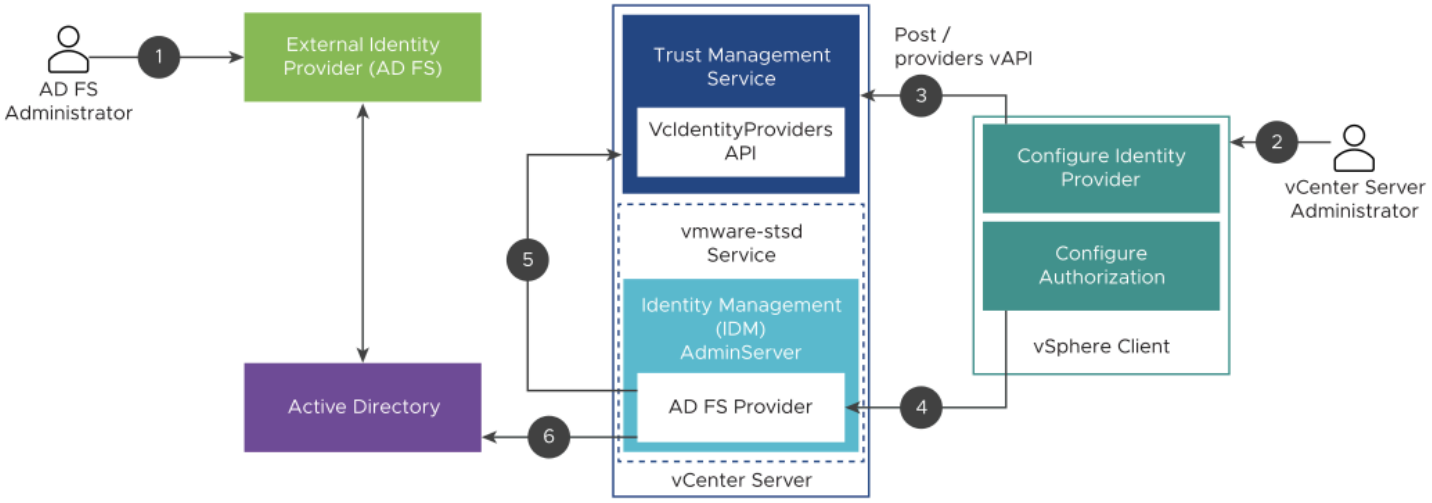
To configure vCenter Identity Provider Federation effectively, you must understand the communication flows that take place.

You can configure vCenter Identity Provider Federation for AD FS, Microsoft Entra ID (formerly called Azure AD), Okta, or PingFederate.

vCenter Identity Provider Federation Configuration Process Flow for AD FS

The following figure shows the process flow that occurs when configuring vCenter Identity Provider Federation for AD FS.

Figure 35: vCenter Identity Provider Federation Configuration Process Flow for AD FS



vCenter, AD FS, and Active Directory interact as follows.

1. The AD FS administrator configures an AD FS OIDC Application for vCenter.
2. The vCenter administrator logs in to the vCenter using the vSphere Client.
3. The vCenter administrator adds an AD FS identity provider to vCenter, and also enters information about the Active Directory domain.
   vCenter needs this information to make an LDAP connection to the Active Directory domain of the AD FS server. Using this connection, vCenter searches for users and groups, and adds them to vCenter local groups in the next step. See the section titled "Searching the Active Directory Domain" that follows for more information.
4. The vCenter administrator configures authorization permissions in vCenter for AD FS users.
5. The AD FS Provider queries the VcIdentityProviders API to get the LDAP connection information for the Active Directory source.
6. The AD FS Provider searches Active Directory for the queried users or groups to finish the Authorization configuration.

Searching the Active Directory Domain

You configure AD FS as the external identity provider in vCenter by using the Configure Main Identity Provider wizard in the vSphere Client. As part of the configuration process, you must enter information about your Active Directory domain, including user and group distinguished name information. Configuration of AD FS for authentication requires this Active Directory connection information. This connection is necessary to search for and map Active Directory user names and groups to roles and permissions in vCenter, whereas AD FS is used for the authentication of the user. This step of the Configure Main Identity Provider wizard does not create an Active Directory Over LDAP identity source. Rather, vCenter uses this information to establish a valid search-capable connection to your Active Directory domain to find users and groups there.

Consider an example using the following distinguished name entries:

- Base distinguished name for users: cn=Users,dc=corp,dc=local
- Base distinguished name for groups: dc=corp,dc=local
- User name: cn=Administrator,cn=Users,dc=corp,dc=local

If the AdfsUser@corp.local user is a member of the ADGroup@corp.local group, entering this information in the wizard allows a vCenter administrator to search for and find the ADGroup@corp.local group and add it to the vCenter Administrators@vsphere.local group. As a result, the AdfsUser@corp.local user is granted administrative privileges in vCenter upon logging in.

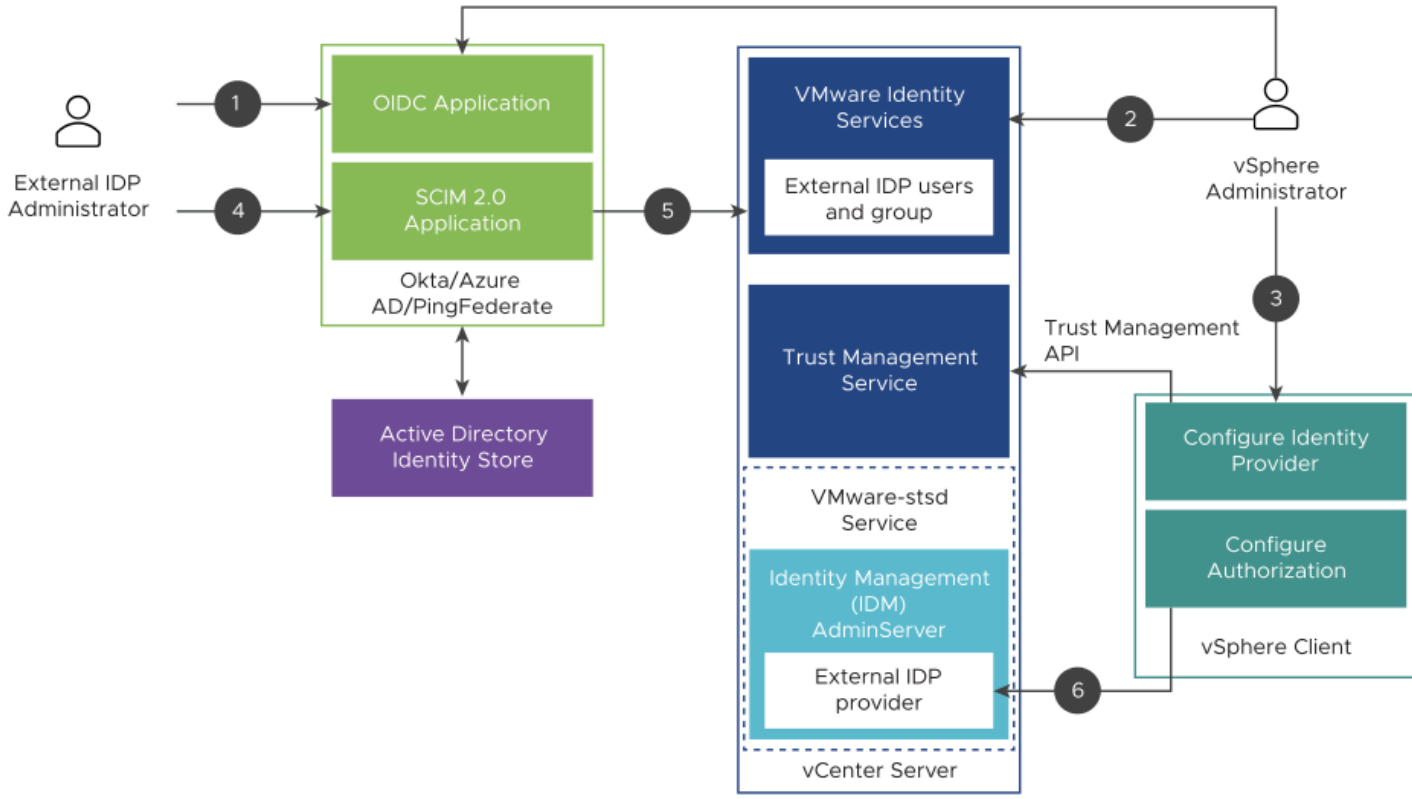
vCenter also uses this search process when you configure global permissions for Active Directory users and groups. In both cases, either configuring global permissions, or adding a user or group, you select the domain you entered for your

AD FS identify provider from the **Domain** drop-down menu to search for and select users and groups from your Active Directory domain.

vCenter Identity Provider Federation Configuration Process Flow Using VMware Identity Services

To configure Okta, Microsoft Entra ID, and PingFederate, you use VMware Identity Services. The following figure shows the process flow that occurs when configuring vCenter Identity Provider Federation using VMware Identity Services.

Figure 36: vCenter Identity Provider Federation Configuration Process Flow using VMware Identity



Services

vCenter, VMware Identity Services, and Active Directory interact as follows.

1. The external IDP administrator configures an OIDC Application for vCenter.
2. The vCenter administrator logs in to the vCenter using the vSphere Client, adds an identity provider to vCenter, and also enters domain information.
3. The vCenter administrator gives the Redirect URI (obtained from the identity provider configuration page in the vSphere Client) to the identity provider administrator to add to the OIDC Application created in step 2.
4. The external IDP administrator configures a SCIM 2.0 Application.
5. The external IDP administrator assigns the users and groups to the SCIM 2.0 Application, and pushes users and groups to vCenter.
6. The vCenter administrator configures authorization permissions in vCenter for external IDP users.

External IDP Users and Groups

Because an external identity provider uses System for Cross-domain Identity Management (SCIM) for users and groups, those users and groups reside in your vCenter. When you search for users and groups in your external identity provider, for example, to assign permissions, the search happens locally on the vCenter.

vCenter also uses this search process when you configure global permissions for external IDP users and groups. In both cases, either configuring global permissions, or adding a user or group, you select the domain you entered for your identity provider from the **Domain** drop-down menu to search for and select users and groups from your domain.

Use the Trusted Root Certificates Store Instead of the JRE truststore

If you imported a root CA certificate issued by your own internal Certificate Authority to the JRE truststore in vSphere 7.0, starting in vSphere 7.0 Update 1, you can register the certificate to the Trusted Root Certificates Store.

To configure vCenter Identity Provider Federation in vSphere 7.0 with a root CA certificate that was issued by your own internal Certificate Authority, you had to import it to the JRE truststore. Starting in vSphere 7.0 Update 1, you can register the certificate to the Trusted Root Certificates Store. This change means that you should add the root CA certificate that was issued by your own internal Certificate Authority to the Trusted Root Certificates Store (also called the VMware Endpoint Certificate Store, or VECS). Certificates in the JRE truststore continue to function, however, vCenter is standardizing on using the Trusted Root Certificates Store.

1. Log in with the vSphere Client to the vCenter.

   Note:
   To learn more, see Add a Trusted Root Certificate to the Certificate Store Using the vSphere Client.

2. Navigate to **Administration** > **Certificates** > **Certificate Management**.
3. Next to **Trusted Root Certificates**, click **Add**.
4. Browse for the AD FS root certificate and click **Add**.
   The certificate is added in a panel under **Trusted Root Certificates**.

Configure vCenter Identity Provider Federation for AD FS

After installing or upgrading to vSphere 7.0 or later, you can configure vCenter Identity Provider Federation for AD FS as an external identity provider.

Note:
This process of configuring an AD FS identity provider requires that you have administrative access to both your vCenter and your AD FS server. During the configuration process, you enter information first in your vCenter, then in your AD FS server, then in your vCenter.

Active Directory Federation Services requirements:

- AD FS for Windows Server 2016 or later must already be deployed.
- AD FS must be connected to Active Directory.
- An Application Group for vCenter must be created in AD FS as part of the configuration process. See the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=78029.
- An AD FS server certificate (or a CA or intermediate certificate that signed the AD FS server certificate) that you add to the Trusted Root Certificates Store.
- You have created a vCenter administrators group in AD FS that contains the users you want to grant vCenter administrator privileges to.

For more information about configuring AD FS, see the Microsoft documentation.

vCenter and other requirements:

- vSphere 7.0 or later
- vCenter must be able to connect to the AD FS discovery endpoint, and the authorization, token, logout, JWKS, and any other endpoints advertised in the discovery endpoint metadata.
- You need the **VcIdentityProviders** > **Manage** privilege to create, update, or delete a vCenter Identity Provider that is required for federated authentication. To limit a user to view the Identity Provider configuration information only, assign the **VcIdentityProviders** > **Read** privilege.

Note:

These instructions are for vSphere 8.0 Update 1 and later. For vSphere 8.0, see the topic about configuring vCenter identity provider federation for AD FS in the *vSphere Authentication* documentation at https://techdocs.broadcom.com/us/en/vmware-cis/vsphere/vsphere/8-0.html

vCenter supports only one configured external identity provider (one source), and the vsphere.local identity source. You cannot use multiple external identity providers. vCenter Identity Provider Federation uses OpenID Connect (OIDC) for user login to vCenter.

This task describes how to add an AD FS group to the vSphere Administrators group as the way to control permissions. You can also configure privileges using AD FS Authorization through global or object permissions in vCenter . See the *vSphere Security* documentation for details about adding permissions.

CAUTION:

If you use an Active Directory identity source that you previously added to vCenter for your AD FS identity source, do not delete that existing identity source from vCenter. Doing so causes a regression with previously assigned roles and group memberships. Both the AD FS user with global permissions and users that were added to the Administrators group will not be able to log in.

Workaround: If you do not need the previously assigned roles and group memberships, and want to remove the previous Active Directory identity source, remove the identity source before creating the AD FS provider and configuring group memberships in vCenter.

1. Log in with the vSphere Client to the vCenter.
2. Add your AD FS server certificate (or a CA or intermediate certificate that signed the AD FS server certificate) to the Trusted Root Certificates Store.

   Note:
   To learn more, see Add a Trusted Root Certificate to the Certificate Store Using the vSphere Client.

   a) Navigate to **Administration** > **Certificates** > **Certificate Management**.
   b) Next to **Trusted Root Store**, click **Add**.
   c) Browse for the AD FS certificate and click **Add**.

   The certificate is added in a panel under **Trusted Root Certificates**.
3. Start to create the identity provider on vCenter.
   a) Use the vSphere Client to log in as an administrator to vCenter.
   b) Navigate to **Home** > **Administration** > **Single Sign On** > **Configuration**.
   c) Click **Change Provider** and select **ADFS**.

   The **Configure Main Identity Provider** wizard opens.
   d) In the **Prerequisites** panel, review the AD FS and the vCenter requirements.
   e) Click **Run Prechecks**.

   If the precheck finds errors, click **View Details** and take steps to resolve the errors as indicated.
   f) When the Precheck passes, click the confirmation check box then click **Next**.
   g) In the **Users and Groups** panel, enter user and group information for the Active Directory over LDAP connection to search for users and groups.

   vCenter derives the AD domain to use for authorization and permissions from the Base Distinguished Name for users. You can add permissions on vSphere objects only for users and groups from this AD domain. Users or groups from AD child domains or other domains in the AD forest are not supported by vCenter Identity Provider Federation.

Option	Description
Base distinguished name for users	Base Distinguished Name for users.
Base distinguished name for groups	The base Distinguished Name for groups.
Username	ID of a user in the domain who has a minimum of read-only access to Base DN for users and groups.
Password	ID of a user in the domain who has a minimum of read-only access to Base DN for users and groups.

Option	Description
Primary server URL	Primary domain controller LDAP server for the domain. Use the format `ldap://hostname:port` or `ldaps://hostname:port`. The port is typically 389 for LDAP connections and 636 for LDAPS connections. For Active Directory multi-domain controller deployments, the port is typically 3268 for LDAP and 3269 for LDAPS. A certificate that establishes trust for the LDAPS endpoint of the Active Directory server is required when you use `ldaps://` in the primary or secondary LDAP URL.
Secondary server URL	Address of a secondary domain controller LDAP server that is used for failover.
SSL certificates	If you want to use LDAPS with your Active Directory LDAP Server or OpenLDAP Server identity source, click `Browse` to select a certificate.

h) Click **Next**.

i) In the **OpenID Connect** panel, copy the Redirect URI and the Log-out Redirect URI.

Leave the other fields blank for now. You return to the **OpenID Connect** panel after creating the OpenID Connection configuration in the next step.

4. Create an OpenID Connect configuration in AD FS and configure it for vCenter.

To establish a relying party trust between vCenter and an identity provider, you must establish the identifying information and a shared secret between them. In AD FS, you do so by creating an OpenID Connect configuration known as an Application Group, which consists of a Server application and a Web API. The two components specify the information that vCenter uses to trust and communicate with the AD FS server. To enable OpenID Connect in AD FS, see the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=78029.

Note the following when you create the AD FS Application Group.

- You need the two vCenter Redirect URIs obtained in the preceding step.
- Copy the following information from the AD FS Application Group to a file or write it down for use when finishing the creation of the vCenter identity provider in the next step.
  - Client Identifier
  - Shared secret
  - OpenID address of the AD FS server

Note:
If necessary, obtain the OpenID address of your AD FS server by running the following PowerShell command as an AD FS administrator.

```
Get-AdfsEndpoint | Select FullUrl | Select-String openid-configuration
```

Copy the URL that is returned (select only the URL itself, not the closing bracket or the initial `"@{FullUrl="` part).

5. In the vCenter**OpenID Connect** panel:

a) Enter the following information, which you obtained from the previous step when creating the AD FS Application Group:

- Client Identifier
- Shared Secret
- OpenID Address

The Identity Provider Name is automatically filled in as Microsoft ADFS.

b) Click **Next**.

6. Review the information and click **Finish**.

vCenter creates the AD FS identity provider and displays the configuration information.

7. Configure group membership in vCenter for AD FS Authorization.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Users and Groups**.
   c) Click the **Groups** tab.
   d) Click the **Administrators** group and click **Add Members**.
   e) Select the domain from the drop-down menu.
   f) In the text box below the drop-down menu, enter the first few characters of AD FS group that you want to add then wait for the drop-down selection to appear.

      It might take several seconds for the selection to appear as vCenter establishes the connection to and searches Active Directory.
   g) Select the AD FS group and add it to the Administrators group.
   h) Click **Save**.
8. Verify logging in to vCenter with an Active Directory user.

Configure vCenter Identity Provider Federation for Okta

After installing or upgrading to vSphere 8.0 Update 1 or later, you can configure vCenter Identity Provider Federation for Okta as an external identity provider.

Okta requirements:

- You are using Okta and have a dedicated domain space, for example, https://*your-company*.okta.com.
- To perform OIDC logins and manage user and group permissions, you must create the following Okta applications.
  – An Okta native application with OpenID Connect as the sign-on method. The native application must include the grant types of authorization code, refresh token, and resource owner password.
  – A System for Cross-domain Identity Management (SCIM) 2.0 application with an OAuth 2.0 Bearer Token to perform user and group synchronization between the Okta server and the vCenter.

  See the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=90835.
- You have identified the Okta users and groups that you want to share with vCenter. This sharing is a SCIM operation (not an OIDC operation).

Okta connectivity requirements:

- vCenter must be able to connect to the Okta discovery endpoint, and the authorization, token, JWKS, and any other endpoints advertised in the discovery endpoint metadata.
- Okta must also be able to connect with vCenter to send user and group data for the SCIM provisioning.

vCenter requirements:

- vSphere 8.0 Update 1 or later
- On the vCenter where you want to create the Okta identity source, verify that the VMware Identity Services are activated.

  Note:
  When you install or upgrade to vSphere 8.0 Update 1 or later, VMware Identity Servers are activated by default. You can use use the vCenter Management Interface to confirm the status of the VMware Identity Services. See Stop and Start the VMware Identity Services.

vSphere privileges requirements:

- You must have the **VcIdentityProviders** > **Manage** privilege to create, update, or delete a vCenter Identity Provider that is required for federated authentication. To limit a user to view the Identity Provider configuration information only, assign the **VcIdentityProviders** > **Read** privilege.

Enhanced Linked Mode requirements:

- You can configure vCenter Identity Provider Federation for Okta in an Enhanced Linked Mode configuration. When you configure Okta in an Enhanced Link Mode configuration, you configure the Okta identity provider to use VMware Identity Services on a single vCenter system. For example, if your Enhanced Mode Link configuration consists of two vCenter systems, only one vCenter and its instance of VMware Identity Services is used to communicate with the Okta

server. If this vCenter system becomes unavailable, you can configure VMware Identity Services on other vCenter in the ELM configuration to interact with your Okta server. For more information, see Activation Process for External Identity Providers in Enhanced Linked Mode Configurations.

- When configuring Okta as an external identity provider, all the vCenter systems in an Enhanced Linked Mode configuration must run at least vSphere 8.0 Update 1.

Networking requirements:

- If your network is not publicly available, you must create a network tunnel between your vCenter system and your Okta server, then use the appropriate publicly accessible URL as the Base Uri.

vCenter supports only one configured external identity provider (one source), and the vsphere.local identity source (local source). You cannot use multiple external identity providers. vCenter Identity Provider Federation uses OpenID Connect (OIDC) for user login to vCenter.

You can configure privileges using Okta groups and users through global or object permissions in vCenter. See the *vSphere Security* documentation for details about adding permissions.

1. Create an OpenID Connect application in Okta and assign groups and users to the OpenID Connect application.

   To create the OpenID Connect application and assign groups and users, see the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=90835. Follow the steps in the section titled "Create the OpenID Connect Application." After you create the Okta OpenID Connect application, copy the following information from the Okta OpenID Connect application to a file for use when configuring the vCenter identity provider in the next step.

   - Client Identifier
   - Client secret (shown as Shared secret in the vSphere Client)
   - Active Directory domain information, or Okta domain information if you are not running Active Directory

2. To create the identity provider on vCenter:
   a) Use the vSphere Client to log in as an administrator to vCenter.
   b) Navigate to **Home** > **Administration** > **Single Sign On** > **Configuration**.
   c) Click **Change Provider** and select **Okta**.

      The **Configure Main Identity Provider** wizard opens.
   d) In the **Prerequisites** panel, review the Okta and the vCenter requirements.
   e) Click **Run Prechecks**.

      If the precheck finds errors, click **View Details** and take steps to resolve the errors as indicated.
   f) When the Precheck passes, click the confirmation checkbox then click **Next**.
   g) In the **Directory Information** panel, enter the following information.

      - Directory Name: Name of the local directory to create on vCenter that stores the users and groups pushed from Okta. For example, `vcenter-okta-directory`.
      - Domain Name(s): Enter the Okta domain names that contain the Okta users and groups you want to synchronize with vCenter.

        After you enter your Okta domain name, click the Plus icon (+) to add it. If you enter multiple domain names, specify the default domain.

   h) Click **Next**.
   i) In the **OpenID Connect** panel, enter the following information.

      - Redirect UI: Filled in automatically. You give the redirect UI to your Okta administrator for use in creating the OpenID Connect application.
      - Identity Provider Name: Filled in automatically as Okta.
      - Client Identifier: Obtained when you created the OpenID Connect application in Okta in step 1. (Okta refers to Client Identifier as the Client ID.)
      - Shared Secret: Obtained when you created the OpenID Connect application in Okta in step 1. (Okta refers to Shared Secret as the Client Secret.)
      - OpenID Address: Takes the form https://*`Okta domain space`*/oauth2/default/.well-known/openid-configuration.

        For example, if your Okta domain space is example.okta.com, then the OpenID Address is: `https://example.okta.com/oauth2/default/.well-known/openid-configuration`

See https://developer.okta.com/docs/reference/api/oidc/#well-known-openid-configuration for more information.

j) Click **Next**.

k) Review the information and click **Finish**.

vCenter creates the Okta identity provider and displays the configuration information.

l) If necessary, scroll down and click the **Copy** icon for the Redirect URI and save it to a file.

You use the Redirect URI in the Okta OpenID Connection application.

m) Click the **Copy** icon for the Tenant URL and save it to a file.

Note:
If your network is not publicly available, you must create a network tunnel between your vCenter system and your Okta server. After creating the network tunnel, use the appropriate publicly accessible URL as the Base Uri.

n) Under **User Provisioning**, click **Generate** to create the secret token, select the token lifespan from the drop-down, then click **Copy to Clipboard**. Save the token to a secure location.

You use the Tenant URL and the token in the Okta SCIM 2.0 application. The Okta SCIM 2.0 application uses the token to synchronize the Okta users and groups into VMware Identity Services. This information is necessary to push Okta users and groups from Okta to vCenter.

3. Return to the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=90835 to update the Okta Redirect URI.

   Follow the steps in the section titled "Update the Okta Redirect URI."

4. To create the SCIM 2.0 application, remain in the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=90835.

   Follow the steps in the section titled "Create the SCIM 2.0 Application and Push Users and Groups to vCenter ."

   When done creating the SCIM 2.0 application as described in the knowledge base article, continue with the next step.

5. Configure vCenter for Okta Authorization.

   You can either assign Okta users to a vCenter group or assign inventory-level and global permissions to Okta users. The minimum permission required for logging in is Read-Only.

   To assign Okta users to a group, see Add Members to a vCenter Single Sign-On Group. To assign inventory-level and global permissions to Okta users, see the topic about managing permissions for vCenter components in the *vSphere Security* documentation.

6. Verify logging in to vCenter with an Okta user.

Configure vCenter Identity Provider Federation for Microsoft Entra ID

After installing or upgrading to vCenter 9.1, you can configure vCenter Identity Provider Federation for Microsoft Entra ID (formerly called Azure AD) as an external identity provider.

Microsoft Entra ID requirements:

- You are customer of Microsoft and have a Microsoft Entra ID account.

Microsoft Entra ID Connectivity requirements:

- You have created an enterprise (non-gallery) application with OpenID Connect as a sign-on method.
- Add authorization code, refresh token and resource owner password as grant types in the created application.
- For user and group sync, you need to configure VMware Identity Services Gallery Application for SCIM 2.0 provisioning in Microsoft Entra ID with OAuth 2.0 Bearer Token.

vCenter requirements:

- vCenter 9.1 or later, with the VMware Identity Services activated (they are activated by default).
- On the vCenter where you want to create the Microsoft Entra ID identity source, verify that the VMware Identity services are activated.
- The users and groups from the identity provider are provisioned in your vCenter.

vSphere privileges requirements:

- You must have the **VcIdentityProviders.Manage** privilege to create, update, or delete a vCenter Identity Provider that is required for federated authentication. To limit a user to view the Identity Provider configuration information only, assign the **VcIdentityProviders.Read** privilege.

Enhanced Linked Mode requirements:

- You can configure vCenter Identity Provider Federation for Microsoft Entra ID in an Enhanced Linked Mode configuration. When you configure Microsoft Entra ID in an Enhanced Link Mode configuration, you configure the Microsoft Entra ID identity provider to use VMware Identity Services on a single vCenter system. For example, if your Enhanced Mode Link configuration consists of two vCenter systems, only one vCenter and its instance of VMware Identity Services is used to communicate with the Microsoft Entra ID server. If this vCenter system becomes unavailable, you can configure VMware Identity Services on other vCenter systems in the ELM configuration to interact with your Microsoft Entra ID server. For more information, see Activation Process for External Identity Providers in Enhanced Linked Mode Configurations.
- When configuring Microsoft Entra ID as an external identity provider, all the vCenter systems in an Enhanced Linked Mode configuration must run at least vSphere 8.0 Update 2.

Networking requirements:

- If your network is not publicly available, you must create a network tunnel between your vCenter system and your Microsoft Entra ID server, then use the appropriate publicly accessible URL as the Base Uri.

vCenter supports only one configured external identity provider (one source), and the vsphere.local identity source (local source). You cannot use multiple external identity providers. vCenter Identity Provider Federation uses OpenID Connect (OIDC) for user login to vCenter.

You can configure privileges using Microsoft Entra ID groups and users through global or object permissions in vCenter. See the *vSphere Security* documentation for details about adding permissions.

For a walk-through of the configuration process, see the following video:

vCenter Authentication: AzureAD/Entra ID integration | vSphere 8 Update 2

1. Create an OpenID Connect application in Microsoft Entra ID and assign groups and users to the OpenID Connect application.

   To create the OpenID Connect application and assign groups and users, see the Broadcom knowledge base article: 322179. Follow the steps in the section titled "Create the OpenID Connect Application." After you create the OpenID Connect application, copy the following information from the Microsoft Entra ID OpenID Connect application to a file for use when configuring the vCenter identity provider in the next step.

   - Client Identifier
   - Client secret (shown as Shared secret in the vSphere Client).
   - Active Directory domain information, or Microsoft Entra ID domain information if you are not running Active Directory.

2. To create the identity provider on vCenter:
   a) Use the vSphere Client to log in as an administrator to vCenter.
   b) Navigate to **Home** > **Administration** > **Single Sign On** > **Configuration**.
   c) Click **Change Provider** and select **Microsoft Entra ID**.

      The **Configure Main Identity Provider** wizard opens.
   d) In the **Prerequisites** panel, review the Microsoft Entra ID and the vCenter requirements.
   e) Click **Run Prechecks**.

      If the precheck finds errors, click **View Details** and take steps to resolve the errors as indicated.
   f) When the Precheck passes, click the confirmation check box then click **Next**.
   g) In the **Directory Information** panel, enter the following information.

      - Directory Name: Name of the local directory to create on vCenter that stores the users and groups pushed from Microsoft Entra ID. For example, `vcenter-entraid-directory`.
      - Domain Names: Enter the Microsoft Entra ID domain names that contain the Microsoft Entra ID users and groups you want to synchronize with vCenter.

After you enter your Microsoft Entra ID domain name, click the Plus icon (+) to add it. If you enter multiple domain names, specify the default domain.

h) Click **Next**.

i) In the **OpenID Connect** panel, enter the following information.

- Redirect UI: Filled in automatically. You give the redirect UI to your Microsoft Entra ID administrator for use in creating the OpenID Connect application.
- Identity Provider Name: Filled in automatically as Microsoft Entra ID.
- Client Identifier: Obtained when you created the OpenID Connect application in Microsoft Entra ID in step 1. (Microsoft Entra ID refers to Client Identifier as the Client ID.)
- Shared Secret: Obtained when you created the OpenID Connect application in Microsoft Entra ID in step 1. (Microsoft Entra ID refers to Shared Secret as the Client Secret.)
- OpenID Address: Takes the form https://*`Microsoft Entra ID domain space`*/oauth2/default/.well-known/openid-configuration.

  For example, if your Microsoft Entra ID domain space is example.EntraID.com, then the OpenID Address is: `https://example.EntraID.com/oauth2/default/.well-known/openid-configuration`

j) Click **Next**.

k) Review the information and click **Finish**.

vCenter creates the Microsoft Entra ID identity provider and displays the configuration information.

l) If necessary, scroll down and click the **Copy** icon for the Redirect URI and save it to a file.

You use the Redirect URI in the Microsoft Entra ID OpenID Connection application.

m) Click the **Copy** icon for the Tenant URL and save it to a file.

Note:
If your network is not publicly available, you must create a network tunnel between your vCenter system and your Microsoft Entra ID server. After creating the network tunnel, use the appropriate publicly accessible URL as the Base URI.

n) Under **User Provisioning**, click **Generate** to create the secret token, select the token lifespan from the drop-down, then click **Copy to Clipboard**. Save the token to a secure location.

You use the Tenant URL and the token in the Microsoft Entra ID SCIM 2.0 application. The Microsoft Entra ID SCIM 2.0 application uses the token to synchronize the Microsoft Entra ID users and groups into VMware Identity Services. This information is necessary to push Microsoft Entra ID users and groups from Microsoft Entra ID to vCenter.

3. Return to the Broadcom knowledge base article: 322179 to update the Microsoft Entra ID Redirect URI.

   Follow the steps in the section titled "Update the Azure AD Redirect URI."

4. To create the SCIM 2.0 application, remain in the Broadcom knowledge base article: 322179.

   Follow the steps in the section titled "Create the SCIM 2.0 Application and Push Users and Groups to vCenter."

   When done creating the SCIM 2.0 application as described in the knowledge base article, continue with the next step.

5. Configure the group membership in vCenter for Microsoft Entra ID Authorization.

   You must configure group membership before Microsoft Entra ID users can log in to vCenter.

a) In the vSphere Client, while logged in as a local administrator, go to **Administration** > **Single Sign On** > **Users and Groups**.
b) Click the **Groups** tab.
c) Click the **Administrators** group and click **Add Members**.
d) Select the domain name of the Microsoft Entra ID group that you want to add from the drop-down menu.
e) In the text box below the drop-down menu, enter the first few characters of Microsoft Entra ID group that you want to add then wait for the drop-down selection to appear.
f) Select the Microsoft Entra ID group and add it to the Administrators group.
g) Click **Save**.

6. Verify logging in to vCenter with a Microsoft Entra ID user.
7. To assign inventory-level and global permissions to Microsoft Entra ID users, see the topic about managing permissions for vCenter components in the *vSphere Security* documentation.

Configuring vCenter Identity Provider for PingFederate

After installing or upgrading to vSphere 9.0, you can configure vCenter Identity Provider Federation for PingFederate as an external identity provider.

High-Level Steps to Configure vCenter Identity Provider for PingFederate

Configuring vCenter for PingFederate involves the following high-level steps:

1. On PingFederate, creating the vCenter/VMware Identity Services specific configuration, including the scopes and common configuration for PingFederate workflows.
2. On PingFederate, creating global items, including the Password Grant Flow configuration and Authorization Code Flow configuration.
3. On PingFederate, installing the SCIM Provisioner.
4. On vCenter, creating the PingFederate identity provider.
5. On PingFederate, creating the SCIM Application (SP Connection).
6. On vCenter, authorizing PingFederate users.

Note:
The instructions in this documentation create a typical setup for your PingFederate server. Your environment might differ, and thus you might make different selections.

Prerequisites to Configure vCenter Identity Provider for PingFederate

PingFederate requirements:

- You have installed an on-premises PingFederate server.
- From the vCenter on which you configure the PingFederate identity provider, you must obtain the trusted root certificates and import them into the PingFederate server.
- Optionally, you might need to import the PingFederate SSL certificate, or certificate chain, to the vCenter, if that certificate is self-signed (that is, not issued by a well-known, public Certificate Authority). If the PingFederate SSL certificate or one of the certificates in the chain was issued by a well-known Certificate Authority, vCenter automatically trusts that certificate, and you do not need to import it. If you are using one or more intermediate signing authorities for your PingFederate server SSL certificate, include the entire chain of certificates.

  To export the PingFederate SSL certificate, in the PingFederate Admin Console, go to **Security** > **SSL Server Certificates**, select the default certificate, and select **Export** from the **Select Action** drop-down.

  You import the PingFederate SSL certificate using the vSphere Client in the **OpenID Connect** panel as part of the configure identity provider workflow.
- To perform OIDC logins and manage user and group permissions, you must create the following PingFederate applications.
  – A PingFederate native application with OpenID Connect as the sign-on method. The native application must include the grant types of authorization code, refresh token, and resource owner password.

  - A System for Cross-domain Identity Management (SCIM) 2.0 application (in PingFederate, this is called the SP Connection), with an OAuth 2.0 Bearer Token to perform user and group synchronization between the PingFederate server and the vCenter.
- You have identified the PingFederate users and groups that you want to share with vCenter. This sharing is a SCIM operation (not an OIDC operation).

PingFederate connectivity requirements:

- vCenter must be able to connect to the PingFederate discovery endpoint, and the authorization, token, JWKS, and any other endpoints advertised in the discovery endpoint metadata.
- PingFederate must also be able to connect with vCenter to send user and group data for the SCIM provisioning.

vCenter requirements:

- vSphere 8.0 Update 3
- On the vCenter where you want to create the PingFederate identity source, verify that the VMware Identity Services are activated.

  Note:
  When you install or upgrade to vSphere 8.0 Update 1 or later, VMware Identity Servers are activated by default. You can use the vCenter Management Interface to confirm the status of the VMware Identity Services. See Stop and Start the VMware Identity Services.

vSphere privileges requirements:

- You must have the **VcIdentityProviders** > **Manage** privilege to create, update, or delete a vCenter Identity Provider that is required for federated authentication. To limit a user to view the Identity Provider configuration information only, assign the **VcIdentityProviders** > **Read** privilege.

Enhanced Linked Mode requirements:

- You can configure vCenter Identity Provider Federation for PingFederate in an Enhanced Linked Mode configuration. When you configure PingFederate in an Enhanced Link Mode configuration, you configure the PingFederate identity provider to use VMware Identity Services on a single vCenter system. For example, if your Enhanced Mode Link configuration consists of two vCenter systems, only one vCenter and its instance of VMware Identity Services is used to communicate with the PingFederate server. If this vCenter system becomes unavailable, you can configure VMware Identity Services on other vCenter in the ELM configuration to interact with your PingFederate server. For more information, see Activation Process for External Identity Providers in Enhanced Linked Mode Configurations.
- When configuring PingFederate as an external identity provider, all the vCenter systems in an Enhanced Linked Mode configuration must run at least vSphere 8.0 Update 3.

Create the Scopes

PingFederate supports the use of scopes to constrain and define access privileges.

Review the Prerequisites to Configure vCenter Identity Provider for PingFederate.

Log in to the PingFederate Admin console with an Administrator Account.

1. Go to **System** > **OAuth Settings** > **Scope Management**.
2. On the **Common Scopes** tab, add the following **Scope Values** along with a description. Click **Add** after entering each value and description.
   - **openid**
   - **profile**
   - **email**
3. Skip the **Exclusive Scopes** tab.
4. On the **Default Scope** tab, enter a description for **Default Scope**.
   A description is required. If **Default Scope Description** is empty, PingFederate logs the following error:

   The requested scope is invalid, unknown, malformed, or exceeds that which the client is permitted to request.

5. Click **Save**.

Continue with Create a Common Configuration for PingFederate Workflows.

Create a Common Configuration for PingFederate Workflows

Creating the common configuration for PingFederate includes creating the Access Token Manager, the objectID Attribute, the OpenID Connect Policy, and the OAuth Client Application.

Complete the following task:

- Create the Scopes

Log in to the PingFederate Admin console with an Administrator Account.

1. Create the Access Token Manager.
   a) Go to **Applications** > **OAuth** > **Access Token Management**.
   b) Click **Create New Instance**.
   c) On the **Type** tab:
      - **Instance Name**: Enter an instance name. For example, vIDB Access Token Manager.
      - **Instance ID**: Enter the instance ID. For example, vIDB.
      - **Type**: Select **JSON Web Tokens**.
      - **Parent Instance**: Leave the default, **None**.
   d) On the **Instance Configuration** tab:
      - **Use Centralized Signing Key**: Select the checkbox.
        Leaving this checkbox unselected causes PingFederate to expect "Active Signing Certificate Key ID" to be configured.
      - **JWS Algorithm**: Select an algorithm. For example, **RSA using SHA-256**.
      - At the bottom of the screen, click **Show Advanced Fields**.
        – **JWT ID Claim Length**: Add a number greater than zero (0). For example, 24. If you do not enter a value, the JTI claim is omitted in the access token.
   e) Click **Next**.
   f) On the **Access Token Attribute Contract** tab:
      - In the **Extend the Contract** text box, add the following claims to be generated in the Ping access token. Click **Add** after entering each claim.
        – **aud**
        – **iss**
        – **exp**
        – **iat**
        – **userName**
      - **Subject Attribute Name**: Select one claim to be used for auditing purposes. For example, **iss**.
   g) Click **Next** twice to skip the **Resource URIs** and **Access Control** tabs.
   h) Click **Save**.
2. Create the OpenID Connect Policy.
   a) Go to **Applications** > **OAuth** > **OpenID Connect Policy Management**.
   b) Click **Add Policy**.
   c) On the **Manage Policy** tab:
      - **Policy ID**: Enter a policy ID. For example, OIDC.
      - **Name**: Enter a policy name. For example, OIDC Policy.
      - **Access Token Manager**: Select the access token manager that you previously created. For example, vIDB Access Token Manager.

d) Click **Next**.
e) On the **Attribute Contract** tab:
   - Click **Delete** to remove all the attributes except **sub**. Otherwise, you must map the attributes to a value in the **Contract Fulfillment** tab later.
f) Click **Next**, then click **Next** again to skip the **Attributes Scope** tab.
g) On the **Attribute Sources & User Lookup** tab, click **Add Attribute Source**.
   After entering the information on each tab that follows, click **Next** to advance.
   - **Data Store**:
     – **Attribute Source ID**: Enter an attribute source ID. For example, vIDBLDAP.
     – **Attribute Source Description**: Enter a description. For example: vIDBLDAP.
     – **Active Data Store**: Select your Active Directory or OpenLDAP domain name from the drop-down.
   - **LDAP Directory Search**:
     – **Base DN**: Enter your base DN to find your users and groups.
     – **Search Scope**: Leave the default, **Subtree**.
     – **Attributes to return from search**: Select **<Show All Attributes>** and select **objectGUID**. Click **Add Attribute**.
   - **LDAP Binary Attribute Encoding Types**:
     – **ObjectGUID**: Select **Hex** for the **Attribute Encoding Type**.
   - **LDAP Filter**:
     – **Filter**: Enter a filter. For example, `userPrincipalName=${userName}.`
h) On the **Summary** page, click **Done**.
i) Click **Next** to advance, and on the **Contract Fulfillment** tab, map the **Attribute Contract** for the ID token:

Attribute Contract	Source	Value
sub	Select the Attribute Source ID previously created. In this documentation, the example used is vIDBLDAP.	**objectGUID**

j) Click **Next**, then click **Next** again to skip the **Insurance Criteria** tab.
k) Click **Save**.

3. Create the OAuth Client Application.
   a) Go to **Applications** > **OAuth** > **Clients**.
   b) Click **Add Client**.
   c) On the **Clients | Client** page:
      - **Client ID**: Enter the client ID. For example, vIDB.

      Note:
      Copy and save the client ID for use later when creating the vCenter identity provider for PingFederate.
      - **Name**: Enter a name. For example, vIDB.
      - **Client Authentication**: Select **Client Secret**.
        – **Client Secret**: You can input your own client secret or generate a secret. After you leave this page, you cannot view the secret again. You only have the option to change the secret.

      Note:
      Copy and save the secret for use later when creating the vCenter identity provider.
      - **Redirection URIs**: Enter the redirection URI(s) in the form: `https://`*`vCenter_Server_FQDN`*`:port/federation/t/CUSTOMER/auth/response/oauth2`.
        – Click **Add**.
      - **Allowed Grant Types**: Check **Authorization Code**, **Refresh Token**, **Client Credentials**, and **Resource Owner Password Credentials**.
      - **Default Access Token Manager**: Select the access token manager you previously created. For example, the one used in this documentation is vIDB Access Token Manager.

- **OpenID Connect**: For **Policy**, select the one you previously created. For example, the one used in this documentation is OIDC.

d) Click **Save**.

Continue with Create the Password Grant Flow Configuration.

Create the Password Grant Flow Configuration

For PingFederate to authenticate with vCenter, you set up the password grant flow.

Complete the following tasks:

- Create the Scopes
- Create a Common Configuration for PingFederate Workflows

Log in to the PingFederate Admin console with an Administrator Account.

1. Create the Password Credential Validator.
   a) Go to **System** > **Data & Credential Stores** > **Password Credential Validators**.
   b) Click **Create New Instance**.
   c) In the **Password Credential Validators | Create New Instance** page, enter the information as follows for each tab, then click **Next** to advance.
      - On the **Type** tab:
        – **Instance Name**: Enter the instance name. For example, vIDB Validator.
        – **Instance ID**: Enter the instance ID. For example, vIDB.
        – **Type**: Select **LDAP Username Password Credential Validator**.
      - On the **Instance Configuration** tab:
        – **LDAP Datastore**: Select the data store you are using.
        – **Search Base**: Enter your base DN to find your users and groups.
        – **Search Filter**: Enter a filter. For example, `userPrincipalName=${username}`.
        – **Scope of Search**: Select **Subtree**.
      - On the **Extended Contract** tab:
        – By default, the following are added:
          - **DN**
          - **email**
          - **givenName**
          - **username**
   d) Click **Next** then click **Save**.
2. Map the Validator in the Authorization Server Settings.
   a) Go to **System** > **OAuth Settings** > **Authorization Server Settings**.
   b) In **Password Credentials Validator**, select the one you previously created. For example, this documentation uses vIDB Validator.
   c) Click **Save**.
3. Create the Resource Owner Credentials Grant Mapping.
   a) Go to **Authentication** > **OAuth** > **Resource Owner Credentials Mapping**.
   b) In the **Resource Owner Credentials Grant Mapping** window:
      - **Source Password Validator Instance**: Select the one you previously created and click **Add Mapping**.
   c) In the **Resource Owner Credentials Grant Mapping | Resource Owner Credentials Mapping** page, click **Next** to skip the **Attribute Sources & User Lookup** tab.
   d) On the **Contract Fulfillment** tab:
      - For **USER_KEY**, select **Password Credentials Validator**, and for **Value**, select **username**.

e) Click **Next** to skip the **Insurance Criteria** tab then click **Save**.

4. Create the Access Token Mapping - Map the Password Credentials Validator to the Access Token Manager.

   This mapping is needed for the Password Grant workflow. If the mapping does not exist, PingFederate logs the following error:

   There are no access token managers available for the selected client and authentication context.

   a) Go to **Applications** > **Access Token Mappings**.
      - **Context**: Select the one you previously created. For example, this documentation uses vIDB Validator.
      - **Access Token Manager**: Select the one previously created. For example, this documentation uses vIDB Access Token Manager.
   b) Click **Add Mapping**.
   c) Click **Next** to skip the **Attribute Sources & User Lookup** tab.
   d) On the **Contract Fulfilment** tab, use the following table.

Contract	Source	Value
aud	**Context**	The client ID previously created. For example, the ID used in this documentation is vIDB.
exp	**No Mapping**	-
iat	**Expression**	Enter the following: `@org.jose4j.jwt.NumericDate@now().getValue()`

iss	**Expression**
	(If not visible, see the PingFederate documentation at https://docs.pingidentity.com/r/en-us/pingfederate-120/pf_enable_disable_express.)
		Enter the following:
		`#tmp=#this.get("context.HttpRequest").getOb`
		`#url=new java.net.URL(#tmp),`
		`#protocol=#url.getProtocol(),`
		`#host=#url.getHost(),#port=#url.getPort(),`
		`#result=(#port != -1) ?`
		`@java.lang.String@format("%s://%s:%d", #protocol, #host, #port) :`
		`@java.lang.String@format("%s://%s", #protocol, #host, #port)`

userName	**No Mapping**	- This contract is used later in the LDAP Filter for the OIDC Policy for Authorization Code workflow. For the PingFederate workflow, it is not needed.

e) Click **Next** to skip the **Insurance Criteria** tab then click **Save**.

Continue with Create the Authorization Code Flow Configuration.

Create the Authorization Code Flow Configuration

Creating the authorization code flow in PingFederate involves creating and configuring an IdP adapter.

Complete the following tasks:

- Create the Scopes
- Create a Common Configuration for PingFederate Workflows
- Create the Password Grant Flow Configuration

Log in to the PingFederate Admin console with an Administrator Account.

1. Create the IdP Adapter.
   a) Go to **Authentication** > **Integration** > **IdP Adapters**.
   b) Create **Create New Instance**.
   c) On the **Type** tab:
      - **Instance Name**: Enter a name, for example, HTML Form Auth Adapter.
      - **Instance ID**: Enter an ID, for example, HTMLFormAuthAdapter.
      - **Type**: Select HTML Form IdP Adapter.
      - **Parent Instance**: Select **None**.
   d) Click **Next**.
   e) On the **IdP Adapter** tab:

      Under **Password Credential Validator Instance**, click **Add a new row to 'Credential Validators.'** then select a validator (in this documentation, vIDB Validator is used), and click **Update**.
   f) On the **IdP Adapter** tab:
      - **Realm**: Select **USER_KEY**.
   g) Click **Next**.
   h) Click **Next** to skip the **Extended Contract** tab.
   i) On the **Adapter Attributes** tab:
      - **Unique User Key Attribute**: Select **username** and check **Pseudonym**.
   j) Click **Next** to skip the **Adapter Contract Mapping** tab then click **Save**.
2. Create IdP Adapter Grant Mapping.
   a) Go to **Authentication** > **OAuth** > **IdP Adapter Grant Mapping**.
   b) **Source Adapter Instance**: Select the Adapter instance you just created and click **Add Mapping**.
   c) On the **Attribute Sources & User Lookup** page, click **Add Attribute Source**.
   d) Enter the information as follows for each tab, then click **Next** to advance.
      - On the **Data Store** tab:
        – **Attribute Source ID**: Enter an ID with alphanumeric values.
        – **Attribute Source Description**. Enter a description.
        – **Active Data Store**: Select the active directory in use.
      - On the **LDAP Directory Search** tab:
        – **Base DN**: Enter your base DN to find your users and groups.
        – **Search Scope**: Use the default, **Subtree**.
        – **Attributes to return from search**: Select **<Show All Attributes>**, then, once loaded, from the attribute list, select **userPrincipalName**.
   e) Click **Add Attribute** then click **Next**.
   f) On the **LDAP Filter** tab:
      - **Filter**: Enter the filter. For example, `userPrincipalName=${username}`.
   g) Click **Next** then click **Save**.
   h) In the **IdP Adapter Grant Mapping | IdP Adapter Mapping** page, finish creating the IdP Grant Mapping.

      On the **Contract Fulfillment Lookup** tab, use the following table.

Contract	Source	Value
USER_KEY	Select the source previously created.	**Subject DN**
USER_NAME	Select the source previously created.	**userPrincipalName**

   i) Click **Next** then click **Save**.

      The created IdP Adapter Grant Mapping displays as '***Adapter Name***' **to Persistent Grant Contract**.

3. Map the IdP Adapter to Access Token Manager.
   a) Go to **Applications** > **OAuth** > **Access Token Mappings**.
      - **Context**: Select **IdP Adapter:*`Adapter Name`***.
      - **Access Token Manager**: Select the access token manager instance previously created. For example, in this documentation, it is vIDB Access Token Manager.
   b) Click **Add Mapping**.
      If you do not perform this mapping, PingFederate generates the following log file message:

      There are no mapped authentication sources to choose from. Please map an IdP Adapter or IdP connection first.
   c) Skip the **Attribute Sources & User Lookup** tab, and on the **Contract Fulfillment** tab, use the following table.

Contract	Source	Value
aud	**No Mapping**	-
exp	**No Mapping**	-
iat	**No Mapping**	-
iss	**No Mapping**	-
userName	**Adapter**	**username**

   d) Click **Next** to skip the **Insurance Criteria** tab then click **Save**.

Continue with Install the SCIM Provisioner.

Install the SCIM Provisioner

You create a System for Cross-domain Identity Management (SCIM) application that uses a token to synchronize the PingFederate users and groups into VMware Identity Services.

Complete the following tasks:

- Create the Scopes
- Create a Common Configuration for PingFederate Workflows
- Create the Password Grant Flow Configuration
- Create the Authorization Code Flow Configuration

On the PingFederate server, you must install the SCIM Provisioner to enable the provisioning of users and groups using SCIM.

> **Note:**
> If you are using an existing PingFederate environment, you might have already installed the SCIM Provisioner.

1. Download the SCIM Provisioner from https://marketplace.pingone.com/item/scim-provisioner.
   You must log in to the PingIdentity portal.
2. Copy the `pf-scim-quickconnection-1.4.jar` file to the folder that is mounted to the `/opt/out folder` of your PingFederate server.
   For example, place the file in the `/opt/out/instance/server/default/deploy` folder.
3. View the `/opt/out/instance/bin/run.properties` file and ensure that this setting is present: `pf.provisioner.mode=STANDALONE`
   According to the PingFederate documentation:

   STANDALONE - This server is a standalone instance that runs both the UI console and protocol engine (default).

4. If your PingFederate server instance is running as a container image, and you updated the `run.properties` file, you might need to restart the server. For example:
   a) Connect to the PingFederate server using SSH.
   b) Change to the `/root/ping` directory.
   c) Run the following commands:

```
docker-compose down
docker-compose up
```

The SCIM Connector displays as an option when configuring the user provisioning in Create the SCIM Application (SP Connection).

Continue with Configure vCenter Identity Provider Federation for PingFederate.

Configure vCenter Identity Provider Federation for PingFederate

After installing or upgrading to vSphere 8.0 Update 3, you can configure vCenter Identity Provider Federation for PingFederate as an external identity provider.

Complete the following tasks:

- Create the Scopes
- Create a Common Configuration for PingFederate Workflows
- Create the Password Grant Flow Configuration
- Create the Authorization Code Flow Configuration
- Install the SCIM Provisioner

Ensure that you have the following information from the PingFederate OpenID Connect application:

- Client Identifier
- Client secret (shown as Shared secret in the vSphere Client)
- Active Directory domain information, or PingFederate domain information if you are not running Active Directory

vCenter supports only one configured external identity provider (one source), and the vsphere.local identity source (local source). You cannot use multiple external identity providers. vCenter Identity Provider Federation uses OpenID Connect (OIDC) for user login to vCenter.

You can configure privileges using PingFederate groups and users through global or object permissions in vCenter. See the *vSphere Security* documentation for details about adding permissions.

1. To create the identity provider on vCenter:
   a) Use the vSphere Client to log in as an administrator to vCenter.
   b) Go to **Home** > **Administration** > **Single Sign On** > **Configuration**.
   c) Click **Change Provider** and select **PingFederate**.
      The **Configure Main Identity Provider** wizard opens.
   d) In the **Prerequisites** panel, review the PingFederate and the vCenter and other requirements.
   e) Click **Run Prechecks**.
      If the precheck finds errors, click **View Details** and take steps to resolve the errors as indicated.
   f) When the Precheck passes, click the confirmation checkbox then click **Next**.
   g) In the **Directory Information** panel, enter the following information.
      - Directory Name: Name of the local directory to create on vCenter that stores the users and groups pushed from PingFederate. For example, `vcenter-PingFederate-directory`.
      - Domain Name(s): Enter the PingFederate domain names that contain the PingFederate users and groups you want to synchronize with vCenter.
        After you enter your PingFederate domain name, click the Plus icon (+) to add it. If you enter multiple domain names, specify the default domain.

h) Click **Next**.
i) In the **OpenID Connect** panel, enter the following information.
   - Redirect UI: Filled in automatically. This redirect UI must match what you use in creating the OpenID Connect application in PingFederate.
   - Identity Provider Name: Filled in automatically as PingFederate.
   - Client Identifier: Obtained when you created the OpenID Connect application. (PingFederate refers to Client Identifier as the Client ID.)
   - Shared Secret: Obtained when you created the OpenID Connect application in PingFederate. (PingFederate refers to Shared Secret as the Client Secret.)
   - OpenID Address: Takes the form https://*PingFederate_domain_space*/idp/.well-known/openid-configuration.
     For example, if your PingFederate domain space is example.PingFederate.com, then the OpenID Address is: `https://example.PingFederate.com/idp/.well-known/openid-config`
   - SSL Certificate: Optionally, browse for the PingFederate SSL certificate, or certificate chain, if this certificate was not issued by a well-known, public Certificate Authority, to upload to vCenter. To export the PingFederate SSL certificate, in the Admin Console, go to **Security** > **SSL Server Certificates**, select the default certificate, and select **Export** from the **Select Action** drop-down. For more information, see the article, Exporting a certificate, at https://docs.pingidentity.com/r/en-us/pingfederate-111/nfv1585678806463. You can export the PingFederate SSL certificate without the private key, as it is not needed for the vCenter configuration.
j) Click **Next**.
k) Review the information and click **Finish**.
   vCenter creates the PingFederate identity provider and displays the configuration information.

2. Under **User Provisioning**, click **Generate** to create the secret token, select the token lifespan from the drop-down, then click **Copy to Clipboard**. Save the token to a secure location.
   When you create the PingFederate SP Connection (SCIM application), you use the token to synchronize the PingFederate users and groups into VMware Identity Services.

Continue with Create the SCIM Application (SP Connection).

Create the SCIM Application (SP Connection)

Creating a System for Cross-domain Identity Management (SCIM) 2.0 application is required, so that you can specify which PingFederate users and groups to push to vCenter.

Complete the following tasks:

- Create the Scopes
- Create a Common Configuration for PingFederate Workflows
- Create the Password Grant Flow Configuration
- Create the Authorization Code Flow Configuration
- Install the SCIM Provisioner
- Configure vCenter Identity Provider Federation for PingFederate

1. Add the vCenter Trusted Root Certificate to the PingFederate Server.
   Before you begin, export the trusted root certificate(s) from vCenter. You can obtain the certificate from the file system of the vCenter at `/var/lib/vmware/vmca/root.cer`. Or, see the Knowledge Base article at https://kb.vmware.com/s/article/2108294.
   a) Log in to the PingFederate Admin console with an Administrator Account.
   b) Go to **Security** > **Certificate & Key Management**.
   c) Select **Trusted CAs** then click **Import** to add the SSL certificate of the vCenter .
   d) If your PingFederate server instance is running as a container image, you might need to restart the server to add the certificate to the trust store. For example:
      1. Connect to the PingFederate server using SSH.
      2. Change to the `/root/ping` directory.
      3. Run the following commands:

```
docker-compose down
docker-compose up
```

2. Create the SP Connection.
   a) Log in to the PingFederate Admin console with an Administrator Account.
   b) Go to **Applications** > **Integration** > **SP Connections**.
   c) Click **Create Connection**.
   d) Select **Use a template for this connection** then select **SCIM Connector** from the drop-down.
      If the SCIM Connector option does not appear in the drop-down, check that you placed the SCIM Connector `.jar` file in the correct folder (the `/opt/out` folder of your PingFederate server).
   e) Click **Next**.
   f) Select only **Outbound Provisioning** then click **Next**.
   g) On the **General Info** tab:
      - **Partner's Entity ID (Connection ID)**: Update **SCIM Connector** to a name of your choice.
      - **Connection Name**: Enter a name.
      - **Base URL**: Enter the HTTPS address of the vCenter where you are configuring the PingFederate external identity provider, for example: `https://vcenter1.example.com`.
   h) Click **Next**.
   i) Click **Configure Provisioning**.
      On the **Target** tab:
      - **SCIM URL**: Enter the Usergroup endpoint.
        This is the Tenant URL obtained under **User Provisioning** on the **Configuration** page of the vCenter . For example: `https://vcenter1.example.com/usergroup/t/CUSTOMER/scim/v2`
      - **Authentication Method**: Select **OAuth 2 Bearer Token** from the drop-down.
      - **Access Token**: Paste the Secret Token that was generated from vCenter , and that you should have saved previously. See Step 2 in Configure vCenter Identity Provider Federation for PingFederate.
      - **Unique User Identifier**: Select **userName** from the drop-down.
      - **Filter Expression**: Copy the following expression into the text box: `externalId eq "%s"`
   j) Accept the rest of the default configuration setting values and click **Next**.
      - **Provisioning Options**: **User Create**, **User Update**, and **User Disable/ Delete** are checked.
      - **Remove User Action**: **Disable** is selected.

      Note:
      With **Disable** selected, when users are deleted from the Active Directory, they are not automatically shown as "disabled" in VMware Identity Services. This is expected behavior.
      - In Active Directory, instead of deleting the user on the next provisioning cycle, the user's property becomes "active"="false".
      - The user does not show as "disabled" in VMware Identity Services until another user is created or updated in Active Directory on the next provisioning cycle, and you follow the workaround at After deleting an AD user account, SaaS provisioner does not remove the user in the next provisioning cycle when Group DN is specified.
      - **Group Name Source**: **Common name** is selected.
   k) On the **Manage Channels** tab, click **Create**.
      - On the **Channel Info** tab:
        – **Channel Name**: Enter a name.
        – Accept the **Max threads** and **Timeout (Secs)** default values.
   l) Click **Next**.
      - On the **Source** tab:
        – **Active Data Store**: Choose your Active Directory domain.
   m) Click **Next**.
      - On the **Source Location** tab:

  - **Base DN**: Enter your base DN to find your users and groups.
  - **Users**: Customize to your environment. For example:
    - **Group DN:** Do not use.
    - **Filter**: Enter `(|(objectClass=person)(objectClass=organizationalPerson)(objectClass=user))`.
  - Groups: Customize to your environment. For example:
    - **Group DN**: Do not use.
    - **Filter**: Enter `(objectClass=group)`.

n) Click **Next**.
o) Accept the defaults on the **Attribute Mapping** tab.
p) Click **Next**.

On the **Activation & Summary** tab:

- **Channel Status**: Select **Active**.

q) Click **Done**.

The SP Connection is created and the SP Connections screen is displayed.

r) Click **Done**.
s) On the **Outbound Provisioning** tab, click **Next**.
t) Review the summary then click **Save**.
u) To make the connection active, toggle the **Enabled** slider.

PingFederate now pushes users and groups from the configured data store to vCenter. Allow some time for the push to occur. You can view the pushed users and groups in the vSphere Client. Go to **Administration** > **Single Sign On** > **Users and Groups**, and select the PingFederate domain.

Continue with Configure vCenter for PingFederate Authorization.

Configure vCenter for PingFederate Authorization

You can either assign PingFederate users to a vCenter group or assign inventory-level and global permissions to PingFederate users.

Complete the following tasks:

- Create the Scopes
- Create a Common Configuration for PingFederate Workflows
- Create the Password Grant Flow Configuration
- Create the Authorization Code Flow Configuration
- Install the SCIM Provisioner
- Configure vCenter Identity Provider Federation for PingFederate
- Create the SCIM Application (SP Connection)

The minimum permission required for a PingFederate user to log in is Read-Only.

1. To assign PingFederate users to a group, see Add Members to a vCenter Single Sign-On Group.
2. To assign inventory-level and global permissions to PingFederate users, see the topic about managing permissions for vCenter components in the *vSphere Security* documentation.
3. After assigning a PingFederate user permissions, verify that the user can log in.

Configure VMware Single Sign-On

After installing or upgrading to vSphere 8.0 Update 3, you can configure vCenter hosts for VMware Single Sign-On. When you configure VMware Single Sign-On, you use an external identity provider to sign into your vCenter hosts.

VMware Single Sign-On requirements:

- The vCenter on which you configure VMware Single Sign-On runs vSphere 8.0 Update 3.

- The vCenter hosts you want to connect to run at least vSphere 8.0 Update 1.
- You have configured one of the following external identity providers:
  - Microsoft Entra ID
  - Okta
  - PingFederate
- You must add the trusted root certificate from the vCenter host on which the external identity provider is configured to the vCenter host on which you configure VMware Single Sign-On.

VMware Single Sign-On enables you to connect vCenter hosts in a non-Enhanced Linked Mode configuration. That is, as long as you configure an external identity provider, you can leverage that configuration for single sign-on to other vCenter hosts. The vCenter host on which the external identity provider is configured acts as the identity provider for the other vCenter hosts.

You can configure multiple vCenter hosts to perform VMware Single Sign-On. To do so, you must configure each vCenter host to point to the vCenter host configured with an external identity provider.

After performing the VMware Single Sign-On configuration, you can still log in to your vCenter hosts with a local account.

Note:
VMware Single Sign-On does not share inventories between vCenter hosts as occurs in Enhanced Linked Mode.

1. Download the trusted root certificate from the vCenter host on which the external identity provider is configured. For example, see the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2108294.
2. Upload that trusted root certificate to the vCenter host on which you are configuring VMware SSO.
   See Add a Trusted Root Certificate to the Certificate Store Using the vSphere Client.
3. Use the vSphere Client to log in as an administrator to the vCenter host on which you are configuring VMware SSO.
4. Navigate to **Home** > **Administration** > **Single Sign On** > **Configuration**.
5. Click **Change Provider** and select **VMware SSO**.
   The **Configure Main Identity Provider** wizard opens.
6. In the **Prerequisites** panel, review the vCenter requirements.
7. Click **Run Prechecks**.
   If the precheck finds errors, click **View Details** and take steps to resolve the errors as indicated.
8. When the Precheck passes, click the confirmation checkbox then click **Next**.
9. In the **OpenID Connect** panel, enter the following information.
   - Identity Provider Name: Filled in with VMware SSO.
   - vCenter Server FQDN: Enter the FQDN of the vCenter host where the external identity provider is configured.
   - Port Number: Accept the default of 443, or change to the port you want to use.
   - User Name and Password: Enter the user name and password for an administrator account on this vCenter host where the external identity provider is configured.
10. Click **Next**.
11. Review the information and click **Finish**.
    vCenter creates the VMware SSO provider and displays the configuration information. This vCenter host now contains the same external identity provider configuration as the host on which the configuration was created. For example, when you compare the OpenID configurations between the two hosts, it is the same.
12. Configure this vCenter to use the external identity provider for authorization.
    You can either assign the external identity provider users to a vCenter group or assign inventory-level and global permissions to the users. The minimum permission required for logging in is Read-Only.
    To assign the external identity provider users to a group, see Add Members to a vCenter Single Sign-On Group. To assign inventory-level and global permissions to the users, see the topic about managing permissions for vCenter components in the *vSphere Security* documentation.

13. Verify logging in to this vCenter host with an external identity provider user.

    When you launch the vSphere Client, you see the Welcome to VMware vSphere screen, with the **Sign in with SSO** button. When you click this button, you are redirected to the external identity provider's sign-in screen.

Managing VMware Identity Services

You can stop and start VMware Identity Services, regenerate a SCIM token, and restore deleted SCIM users and groups.

Depending on the task, you use either the vSphere Client or the external identity provider's administration console.

Stop and Start the VMware Identity Services

To configure and run Okta, Microsoft Entra ID (formerly called Azure AD), or PingFederate as an external identity provider, VMware Identity Services must be started on vCenter. By default, when you either install or upgrade to vSphere 8.0 Update 1 or later, VMware Identity Services are started. You use the vCenter Management Interface to manage VMware Identity Services.

When you install or upgrade to vSphere 8.0 Update 1 or later, VMware Identity Services are automatically started. When you configure Okta, Microsoft Entra ID, or PingFederate as an external identity provider, you do not need to start VMware Identity Services, as they are already running. To start or stop VMware Identity Services, you must be root.

You configure the external identity provider on a single vCenter only. That vCenter, through its instance of VMware Identity Services, communicates to the identity provider. The other vCenter systems in the Enhanced Linked Mode configuration also have VMware Identity Services running, however, they do not communicate directly to the identity provider.

Starting in version 8.0 Update 1, vSphere includes the VMware Identity Services to support authenticating to Okta. Starting in version 8.0 Update 2, VMware Identity Services support authenticating to Microsoft Entra ID. Starting in version 8.0 Update 3, VMware Identity Services support authenticating to PingFederate.

1. In a Web browser, go to the vCenter Management Interface at https://*`vcenter-IP-address-or-FQDN`*:5480.
2. Log in as root.

   The default root password is the password that you set while deploying the vCenter.
3. Select **Services**.
4. View the status of VMware Identity Services.
5. To stop or start the service, select **VMware Identity Services**, then click either **Stop** or **Start**.

   After starting VMware Identity Services, no vCenter reboot is necessary.

Regenerate the SCIM Token in vCenter

In vCenter, you can regenerate a System for Cross-Domain Identity Management (SCIM) token for an external identity provider.

You must have created an external identity provider in vCenter.

If you generate another token, it becomes active immediately, and the previous token is revoked.

1. Log in as an administrator with the vSphere Client to the vCenter.
2. Navigate to the Configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Configuration**.
3. On the **Configuration** page, under **User Provisioning**/**Secret Token**, click **Regenerate** to regenerate the secret token, select the token lifespan from the drop-down, then click **Copy to Clipboard**. Save the token to a secure location.
4. The copied token is available for you to update your external identity provider configuration.

Restore Deleted SCIM Users and Groups

If the SCIM-pushed users and groups on your vCenter become out-of-sync with your external identity provider, you can take steps to fix the problem.

When you want to restore an SCIM-pushed user or group that you deleted from your vCenter, you cannot simply push the user or group from your identity provider. Because of the way vCenter uses System for Cross-domain Identity Management (SCIM) for user and group management, you must update the SCIM 2.0 application itself with the missing user or group.

1. Log in to the external IDP Admin console.
2. Navigate to the SCIM 2.0 application.
3. Assign the deleted or missing user or group.
4. Select the appropriate action to delete the pushed group or user to unlink the pushed group or user.
5. Select the appropriate action to push the group.
6. Verify on your vCenter that external IDP synchronized the group or user.

vCenter Single Sign-On

If you are not using an external identity provider, you must understand the underlying architecture of the built-in identity provider, vCenter Single Sign-On, and how it affects installation and upgrades.

vCenter Single Sign-On Components

vCenter Single Sign-On includes the Security Token Service (STS), an administration server, the vCenter Lookup Service, and the VMware Directory Service (vmdir). The VMware Directory Service is also used for certificate management.

During installation, the following components are deployed as part of a vCenter deployment.

STS (Security Token Service)	The STS service issues Security Assertion Markup Language (SAML) tokens. These security tokens represent the identity of a user in one of the identity source types supported by vCenter. The SAML tokens allow interactive, scripted, and service users (including solution users) who authenticate successfully to vCenter Single Sign-On to use any vCenter service that vCenter Single Sign-On supports without authenticating again to each service. The vCenter Single Sign-On service signs all tokens with a signing certificate, and stores the token signing certificate on disk. The certificate for the service itself is also stored on disk.
Administration server	The administration server allows users with administrator privileges to vCenter Single Sign-On to configure the vCenter Single Sign-On server and manage users and groups from the vSphere Client. Initially, only the user administrator@*`your_domain_name`* has these privileges. You can change the vSphere domain when you install vCenter. Do not name the domain name with your Microsoft Active Directory or OpenLDAP domain name.
VMware Directory Service (vmdir)	A VMware Directory Service (vmdir) is associated with the domain you specify during installation and is included in each vCenter deployment. This service is a multi-tenanted, peer-replicating directory service that makes an LDAP directory available on port 389. It also stores and manages vCenter Single Sign-On user accounts and passwords, which are secured by the SHA-512 hashing algorithm. If your environment includes multiple instances of vCenter configured in linked mode, an update of vmdir content in one vmdir instance is propagated to all other instances of vmdir.

	The VMware Directory Service stores not only vCenter Single Sign-On information but also certificate information.
Identity Management Service	Handles identity sources and STS authentication requests.

Using vCenter Single Sign-On with vSphere

When a user logs in to a vSphere component, or when a vCenter solution user accesses another vCenter service, vCenter Single Sign-On performs authentication. Users must be authenticated with vCenter Single Sign-On and have the necessary privileges for interacting with vSphere objects.

vCenter Single Sign-On authenticates both solution users and other users.

- Solution users represent a set of services in your vSphere environment. During installation, VMCA assigns a certificate to each solution user by default. The solution user uses that certificate to authenticate to vCenter Single Sign-On. vCenter Single Sign-On gives the solution user a SAML token, and the solution user can then interact with other services in the environment.
- When other users log in to the environment, for example, from the vSphere Client, vCenter Single Sign-On prompts for a user name and password. If vCenter Single Sign-On finds a user with those credentials in the corresponding identity source, it assigns the user a SAML token. The user can now access other services in the environment without being prompted to authenticate again.

  Which objects the user can view, and what a user can do, is usually determined by vCenter permission settings. vCenter administrators assign those permissions from the **Permissions** interface in the vSphere Client, not through vCenter Single Sign-On. See the *vSphere Security* documentation.

vCenter Single Sign-On and vCenter Users

Users authenticate to vCenter Single Sign-On by entering their credentials on the login page. After connecting to vCenter, authenticated users can view all vCenter instances or other vSphere objects for which their role gives them privileges. No further authentication is required.

After installation, the administrator of the vCenter Single Sign-On domain, administrator@vsphere.local by default, has administrator access to both vCenter Single Sign-On and vCenter. That user can then add identity sources, set the default identity source, and manage users and groups in the vCenter Single Sign-On domain.

After installation, the cloudadmin@vmc.local user vCenter has administrator access to both vCenter Single Sign-On and vCenter. That user can also add identity sources, set the default identity source, and set policies in the vmc.local domain. Certain management operations in the vmc.local domain are restricted to VMware Cloud on AWS operations staff.

All users that can authenticate to vCenter Single Sign-On can reset their password. See Change Your vCenter Single Sign-On Password . Only vCenter Single Sign-On administrators can reset the password for users who no longer have their password.

vCenter Single Sign-On Administrator Users

The vCenter Single Sign-On administrative interface is accessible from the vSphere Client.

To configure vCenter Single Sign-On and manage vCenter Single Sign-On users and groups, the user administrator@vsphere.local or a user in the vCenter Single Sign-On Administrators group must log in to the vSphere Client. Upon authentication, that user can access the vCenter Single Sign-On administration interface from the vSphere Client and manage identity sources and default domains, specify password policies, and perform other administrative tasks.

> **Note:**
> You cannot rename the vCenter Single Sign-On administrator user, which is administrator@vsphere.local by default or administrator@`mydomain` if you specified a different domain during installation. For improved security, consider creating additional named users in the vCenter Single Sign-On domain and assigning them administrative privileges. You can then stop using the administrator account.

Other User Accounts in vCenter

The following user accounts are created automatically within vCenter in the vsphere.local domain (or the default domain that you created at installation). These user accounts are shell accounts. The vCenter Single Sign-On password policy does not apply to these accounts.

Table 87: Other vCenter User Accounts

Account	Description
K/M	For Kerberos key management.
waiter-*random_string*	For Auto Deploy.

ESX Users

Standalone ESX hosts are not integrated with vCenter Single Sign-On. See *vSphere Security* for information on adding an ESX host to Active Directory.

If you create local ESX users for a managed ESX host with the VMware Host Client, ESXCLI, or PowerCLI, vCenter is not aware of those users. Creating local users can therefore result in confusion, especially if you use the same user names. Users who can authenticate to vCenter Single Sign-On can view and manage ESX hosts if they have the corresponding permissions on the ESX host object.

Note:
Manage permissions for ESX hosts through vCenter if possible.

How to Log In to vCenter Components

You can log in by connecting to the vSphere Client.

When a user logs in to a vCenter system from the vSphere Client, the login behavior depends on whether the user is in the domain that is set as the default identity source.

- Users who are in the default domain can log in with their user name and password.
- Users who are in a domain that has been added to vCenter Single Sign-On as an identity source but is not the default domain can log in to vCenter but must specify the domain in one of the following ways.
  - Including a domain name prefix, for example, MYDOMAIN\user1
  - Including the domain, for example, user1@mydomain.com
- Users who are in a domain that is not a vCenter Single Sign-On identity source cannot log in to vCenter. If the domain that you add to vCenter Single Sign-On is part of a domain hierarchy, Active Directory determines whether users of other domains in the hierarchy are authenticated or not.

If your environment includes an Active Directory hierarchy, see the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2064250 for details on supported and unsupported setups.

Groups in the vCenter Single Sign-On Domain

The vCenter Single Sign-On domain (vsphere.local by default) includes several predefined groups. Add users to one of those groups to permit them to perform the corresponding actions.

See Managing vCenter Single Sign-On Users and Groups.

For all objects in the vCenter hierarchy, you can assign permissions by pairing a user and a role with the object. For example, you can select a resource pool and give a group of users read privileges to that resource pool object by giving them the corresponding role.

For some services that are not managed by vCenter directly, membership in one of the vCenter Single Sign-On groups determines the privileges. For example, a user who is a member of the Administrators group can manage vCenter Single Sign-On. A user who is a member of the CAAdmins group can manage the VMware Certificate Authority, and a user who is in the LicenseService.Administrators group can manage licenses.

The following groups are predefined in vsphere.local. Many of these groups are internal to vsphere.local or give users high-level administrative privileges. Add users to any of these groups only after careful consideration of the risks.

CAUTION:
Do not delete any of the predefined groups in the vsphere.local domain. If you do, errors with authentication or certificate provisioning might result.

Table 88: Groups in the vsphere.local Domain

Privilege	Description
Users	Users in the vCenter Single Sign-On domain (vsphere.local by default).
SolutionUsers	Solution users group for vCenter services. Each solution user authenticates individually to vCenter Single Sign-On with a certificate. By default, VMCA provisions solution users with certificates. Do not add members to this group explicitly.
CAAdmins	Members of the CAAdmins group have administrator privileges for VMCA. Do not add members to this group unless you have compelling reasons.
DCAdmins	Members of the DCAdmins group can perform Domain Controller Administrator actions on VMware Directory Service. **Note:** Do not manage the domain controller directly. Instead, use the `vmdir` CLI or the vSphere Client to perform corresponding tasks.
SystemConfiguration.BashShellAdministrators	A user in this group has full access to all the Appliance Management APIs. By default, a user who connects to the vCenter with SSH can access only commands in the restricted shell, but users in this group have Bash Shell Access over SSH and gain full privileges similar to the root user.
ActAsUsers	Members of Act-As Users are allowed to get Act-As tokens from vCenter Single Sign-On.
ExternalIDPUsers	This internal group is not used by vSphere. VMware vCloud Air requires this group.
SystemConfiguration.Administrators	Members of the SystemConfiguration.Administrators group can view and manage the system configuration in the vCenter Management Interface running on port 5480. These users can view services, start and restart services, and troubleshoot services. These users can also access Appliance Management APIs except for those APIs that modify critical system configurations.
DCClients	This group is used internally to allow the management node access to data in VMware Directory Service. **Note:** Do not modify this group. Any changes might compromise your certificate infrastructure.
ComponentManager.Administrators	Members of the ComponentManager.Administrators group can invoke component manager APIs that register or unregister services, that is, modify services. Membership in this group is not necessary for read access on the services.
LicenseService.Administrators	Members of LicenseService.Administrators have full write access to all licensing-related data and can add, remove, assign, and unassign serial keys for all product assets registered in the licensing service.

Privilege	Description
Administrators	Administrators of the VMware Directory Service (vmdir). Members of this group can perform vCenter Single Sign-On administration tasks. Do not add members to this group unless you have compelling reasons and understand the consequences.
TrustedAdmins	Members of this group can perform VMware®vSphere Trust Authority™ configuration and administration tasks. By default, this group does not contain any members. You must add a member to this group so that you can perform vSphere Trust Authority tasks.
AutoUpdate	This group is used internally for vCenter Cloud Gateway.
SyncUsers	This group is used internally for vCenter Cloud Gateway.
vSphereClientSolutionUsers	This group is used internally for the vSphere Client.
ServiceProviderUsers	Members of this group can manage the vSphere with Tanzu and VMware Cloud on AWS infrastructure.
NsxAdministrators	This group is used for VMware NSX.
WorkloadStorage	Workload storage group.
RegistryAdministrators	Members of this group can manage the registry.
NsxAuditors	This group is used for VMware NSX.
NsxViAdministrators	This group is used for VMware NSX.
SystemConfiguration.SupportUsers	Members of the SystemConfiguration.SupportUsers group can access the support bundle API.
SystemConfiguration.ReadOnly	Members of this group can access vCenter appliance read-only operations under Appliance Management.
VCLSAdmin	Members of this group have administrative privileges for vSphere Cluster Services (vCLS).
AnalyticsService.Administrators	This group is used for the VMware Analytics Service APIs.
vStatsGroup	This group is used for vStats collection.

Configuring vCenter Single Sign-On Identity Sources

When a user logs in with just a user name, vCenter Single Sign-On checks in the default identity source whether that user can authenticate. When a user logs in and includes the domain name in the login screen, vCenter Single Sign-On checks the specified domain if that domain has been added as an identity source. You can add identity sources, remove identity sources, and change the default.

You configure vCenter Single Sign-On from the vSphere Client. To configure vCenter Single Sign-On, you must have vCenter Single Sign-On administrator privileges. Having vCenter Single Sign-On administrator privileges is different from having the Administrator role on vCenter or ESX. In a new installation, only the vCenter Single Sign-On administrator (administrator@vsphere.local by default) can authenticate to vCenter Single Sign-On.

You configure vCenter Single Sign-On from the vSphere Client.

Identity Sources for vCenter with vCenter Single Sign-On

You can use identity sources to attach one or more domains to vCenter Single Sign-On. A domain is a repository for users and groups that the vCenter Single Sign-On server can use for user authentication.

> **Note:**
> At any time, only one default domain exists. If a user from a non-default domain logs in, that user must add the domain name to authenticate successfully. The domain name is in the form:
> `DOMAIN\user`

The following identity sources are available.

- Active Directory over LDAP. vCenter Single Sign-On supports multiple Active Directory over LDAP identity sources.

- OpenLDAP versions 2.4 and later. vCenter Single Sign-On supports multiple OpenLDAP identity sources.

  Note:

  A Microsoft Windows update changed the default behavior of Active Directory to require strong authentication and encryption. This change impacts how vCenter authenticates to Active Directory. If you use Active Directory as your identity source for vCenter, you must enable LDAPS. For more information, see https://msrc.microsoft.com/update-guide/en-us/advisory/ADV190023.

Set the Default Domain for vCenter Single Sign-On

Each vCenter Single Sign-On identity source is associated with a domain. vCenter Single Sign-On uses the default domain to authenticate a user who logs in without a domain name. Users who belong to a domain that is not the default domain must include the domain name when they log in.

When a user logs in to a vCenter system from the vSphere Client, the login behavior depends on whether the user is in the domain that is set as the default identity source.

- Users who are in the default domain can log in with their user name and password.
- Users who are in a domain that has been added to vCenter Single Sign-On as an identity source but is not the default domain can log in to vCenter but must specify the domain in one of the following ways.
  - Including a domain name prefix, for example, MYDOMAIN\user1
  - Including the domain, for example, user1@mydomain.com
- Users who are in a domain that is not a vCenter Single Sign-On identity source cannot log in to vCenter. If the domain that you add to vCenter Single Sign-On is part of a domain hierarchy, Active Directory determines whether users of other domains in the hierarchy are authenticated or not.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the Configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Configuration**.
4. Under the **Identity Provider** tab, click **Identity Sources**, select an identity source, and click **Set as Default**.
5. Click **OK**.

   In the domain display, the default domain shows (default) in the Type column.

Managing the vCenter Security Token Service

The vCenter Security Token Service (STS) is a Web service that issues, validates, and renews security tokens.

As a token issuer, the Security Token Service (STS) uses a private key to sign the tokens and publishes the public certificates for services to verify the token signature. vCenter manages the STS signing certificates and stores them in the VMware Directory Service (vmdir). Tokens can have a significant lifetime, and historically might have been signed by any one of multiple keys.

Users present their primary credentials to the STS interface to acquire tokens. The primary credential depends on the type of user.

Table 89: STS Users and Credentials

Type of User	Primary Credentials
Solution user	Valid certificate.
Other users	User name and password available in a vCenter Single Sign-On identity source.

STS authenticates the user based on the primary credentials, and constructs a SAML token that contains user attributes.

By default, the VMware Certificate Authority (VMCA) generates the STS signing certificate. You can refresh the STS signing certificate with a new VMCA certificate. You can also import and replace the default STS signing certificate with a custom or third-party generated STS signing certificate. Do not replace the STS signing certificate unless the security policy of your company requires replacing all certificates.

You can use the vSphere Client to:

- Refresh STS certificates
- Import and replace custom and third-party generated STS certificates
- View STS certificate details, such as the expiration date

You can also use the command line to replace custom and third-party generated STS certificates.

STS Certificate Duration and Expiration

A fresh installation of vSphere 7.0 Update 1 and later creates an STS signing certificate with a duration of 10 years. When an STS signing certificate is close to expiring, an alarm warns you starting at 90 days once per week, and then daily when seven days away.

> **Note:**
> In certain circumstances, replacing your STS signing certificates can change the duration of the certificates. When performing certificate replacement, pay attention to the issuing and expiration dates.

STS Certificate Auto-Renewal

In vSphere 8.0 and later, vCenter Single Sign-On automatically renews a VMCA-generated STS signing certificate. The auto-renewal occurs before the STS signing certificate expires and before triggering the 90-day expiration alarm. If the auto-renewal fails, vCenter Single Sign-On creates an error message in the log file. If necessary, you can refresh the STS signing certificate manually.

> **Note:**
> vCenter Single Sign-On does not perform auto-renewal of custom generated or third-party STS signing certificates.

Refreshing and Importing and Replacing STS Certificates

In vSphere 8.0 and later, refreshing or importing and replacing the STS signing certificates does not require a vCenter restart and so avoids any downtime. Also, in a linked configuration, refreshing or importing and replacing the STS signing certificates on a single vCenter updates the STS certificates on all the linked vCenter systems.

> **Note:**
> In certain circumstances, a refresh or import and replace of STS signing certificates can require you to manually restart the vCenter systems.

Refresh a vCenter STS Certificate Using the vSphere Client

You can refresh your vCenter STS signing certificates using the vSphere Client. The VMware Certificate Authority (VMCA) issues a new certificate and replaces the current certificate.

For certificate management, you must supply the password of the administrator of the local domain (administrator@vsphere.local by default). If you are renewing certificates, you must also supply the vCenter Single Sign-On credentials for a user with administrator privileges on the vCenter system.

When you refresh STS signing certificates, the VMware Certificate Authority (VMCA) issues a new certificate and replaces the current certificate in the VMware Directory Service (vmdir). STS starts using the new certificate to issue new tokens. In an Enhanced Linked Mode configuration, vmdir uploads the new certificate from the issuing vCenter system to all linked vCenter systems. When you refresh STS signing certificates, you do not need to restart the vCenter system, nor any other vCenter system that is part of an Enhanced Linked Mode configuration.

If you are using a custom generated or third-party STS signing certificate, the refresh overwrites that certificate with a VMCA-issued certificate. To update custom generated or third-party STS signing certificates, use the import and replace option. See Import and Replace a vCenter STS Certificate Using the vSphere Client.

The VMCA-issued STS signing certificate is valid for 10 years and is not an external-facing certificate. Do not replace this certificate unless the security policy of your company requires it.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. If the system prompts you, enter the credentials of your vCenter.
5. Under the **STS Signing** tab, select the desired certificate and click **Refresh with vCenter Certificate**.

   If you are using a custom generated or third-party STS signing certificate, the refresh action overwrites that certificate with a VMCA-generated certificate.

   Note:
   If you were using third-party certificates for compliance reasons, the refresh might cause your vCenter systems to go out of compliance. Also, if you are using a custom generated or third-party STS signing certificate, the Security Token Service no longer uses that custom or third-party certificate for token signing.
6. Click **Refresh**.

   The VMCA refreshes the STS signing certificate on this vCenter system and on any linked vCenter systems.
7. Optional: If the **Force Refresh** button appears, vCenter Single Sign-On has detected a problem. Before clicking **Force Refresh**, consider the following potential results.
   - If all the impacted vCenter systems are not running at least vSphere 7.0 Update 3, they do not support the certificate refresh.
   - Selecting **Force Refresh** requires that you restart all vCenter systems and can render those systems inoperable until you do so.

   a) If you are unsure of the impact, click **Cancel** and research your environment.
   b) If you are sure of the impact, click **Force Refresh** to proceed with the refresh then manually restart your vCenter systems.

Import and Replace a vCenter STS Certificate Using the vSphere Client

You can import and replace the vCenter STS certificate with a custom generated or third-party certificate using the vSphere Client.

For certificate management, you must supply the password of the administrator of the local domain (administrator@vsphere.local by default). You also must supply the vCenter Single Sign-On credentials for a user with administrator privileges on the vCenter system.

To import and replace the default STS signing certificate, you must first generate a new certificate. When you import and replace STS signing certificates, the VMware Directory Service (vmdir) uploads the new certificate from the issuing vCenter system to all linked vCenter systems.

The STS certificate is not an external-facing certificate. Do not replace this certificate unless the security policy of your company requires it.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.

3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. If the system prompts you, enter the credentials of your vCenter.
5. Under the **STS Signing** tab, select the desired certificate and click **Import and Replace Certificate**.
6. Select the PEM file.
   The PEM file includes the signing certificate chain and the private key.
7. Click **Replace**.
   The STS signing certificate is replaced on this vCenter system and on any linked vCenter systems. Unless otherwise indicated, you do not need to restart the vCenter systems.

Replace a vCenter STS Certificate Using the Command Line

You can replace the vCenter STS certificate with a custom generated or third-party certificate using the CLI.

Enable SSH login to vCenter. See Manage vCenter Using the vCenter Shell.

To use a company required certificate or to refresh a certificate that is near expiration, you can replace the existing STS signing certificate. To replace the default STS signing certificate, you must first generate a new certificate.

The STS certificate is not an external-facing certificate. Do not replace this certificate unless the security policy of your company requires it.

> **CAUTION:**
> You must use the procedures described here. Do not replace the certificate directly in the file system.

1. Log in to the vCenter shell as root.
2. Create a certificate.
   a) Create a top-level directory to hold the new certificate and verify the location of the directory.

```
mkdir newsts
cd newsts
pwd
#resulting output: /root/newsts
```

   b) Copy the `certool.cfg` file into the new directory.

```
cp /usr/lib/vmware-vmca/share/config/certool.cfg /root/newsts
```

   c) Using a command-line editor such as Vim, open your copy of the `certool.cfg` file and edit it to use the local vCenter IP address and hostname. The country is required and has to be two characters, as shown in the following example.

```
#
# Template file for a CSR request
#

# Country is needed and has to be 2 characters
Country = US
Name = STS
Organization = ExampleInc
OrgUnit = ExampleInc Dev
State = Indiana
Locality = Indianapolis
IPAddress = 10.0.1.32
Email = chen@exampleinc.com
Hostname = homecenter.exampleinc.local
```

d) Generate the key.

```
/usr/lib/vmware-vmca/bin/certool --server localhost --genkey --privkey=/root/newsts/sts.key --pubkey=/root/newsts/sts.pub
```

e) Generate the certificate.

```
/usr/lib/vmware-vmca/bin/certool --gencert --cert=/root/newsts/newsts.cer --privkey=/root/newsts/sts.key --config=/root/newsts/certool.cfg
```

f) Create a PEM file with the certificate chain and private key.

```
cat newsts.cer /var/lib/vmware/vmca/root.cer sts.key > newsts.pem
```

3. Update the STS signing certificate, for example:

```
/opt/vmware/bin/sso-config.sh -set_signing_cert -t vsphere.local /root/newsts/newsts.pem
```

The VMCA refreshes the STS signing certificate on this vCenter system and on any linked vCenter systems.

View the Active vCenter STS Signing Certificate Chain Using the vSphere Client

You can use the vSphere Client to view the active vCenter STS signing certificate chain and the certificate information, such as the valid until date.

1. Log in with the vSphere Client to the vCenter.
2. Enter the user name and password for a user that has at least Read privileges.
3. Navigate to the Certificate Management UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Certificates**, click **Certificate Management**.
4. If the system prompts you, enter the credentials of your vCenter.
5. Under the **STS Signing** tab, select a certificate, then expand the certificate.
   Certificate and issue information is displayed, including:
   - Valid until date
   - A green check for a valid certificate, and an orange check warning of an expired certificate

Determine the Expiration Date of an LDAPS SSL Certificate Using the Command Line

When using Active Directory over LDAPS, you can upload an SSL certificate for the LDAP traffic. SSL certificates expire after a predefined lifespan. You can use the `sso-config.sh` command to view the certificate's expiration date so that you know to replace or renew the certificate before it expires.

Enable SSH login to vCenter. See Manage vCenter Using the vCenter Shell.

vCenter alerts you when an active LDAP SSL certificate is close to its expiration date.

You see certificate expiration information only if you use Active Directory over LDAP or an OpenLDAP identity source and specify an `ldaps://` URL for the server.

1. Log in as root to the vCenter.
2. Run the following command.

```
/opt/vmware/bin/sso-config.sh -get_identity_sources
```

Ignore the SLF4J messages.

3. To determine the expiration date, view the SSL certificate's details and verify the `NotAfter` field.

Managing vCenter Single Sign-On Policies

vCenter Single Sign-On policies enforce the security rules for local accounts and tokens in general. You can view and edit the default vCenter Single Sign-On password policy, lockout policy, and token policy.

Edit the vCenter Single Sign-On Password Policy

The vCenter Single Sign-On password policy determines the password format and password expiration. Password policy applies only to users in the vCenter Single Sign-On domain (vsphere.local).

By default, vCenter Single Sign-On built-in user account passwords expire after 90 days. The vSphere Client reminds you when your password is about to expire.

See Change Your vCenter Single Sign-On Password .

Note:
The administrator account (administrator@vsphere.local) does not get locked out nor does its password expire. Proper security practice is to audit logins from this account and rotate the password regularly.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the Configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Configuration**.
4. Click the **Local Accounts** tab.
5. Click **Edit** for the **Password Policy** row.
6. Edit the password policy.

Option	Description
Description	Password policy description.
Maximum lifetime	Maximum number of days that a password is valid before the user must change it. The maximum number of days you can enter is 999999999. A value of zero (0) means that the password never expires.
Restrict reuse	Number of previous passwords that cannot be reused. For example, if you enter 6, the user cannot reuse any of the last six passwords.
Maximum length	Maximum number of characters that are allowed in the password.
Minimum length	Minimum number of characters required in the password. The minimum length must be no less than the combined minimum of alphabetic, numeric, and special character requirements.
Character requirements	Minimum number of different character types that are required in the password. You can specify the number of each type of character, as follows: • Special: & # % • Alphabetic: A b c D • Uppercase: A B C • Lowercase: a b c • Numeric: 1 2 3 • Identical Adjacent: The number must be greater than 0. For example, if you enter 1, the following password is not allowed: p@$$word. The minimum number of alphabetic characters must be no less than the combined uppercase and lowercase characters. Non-ASCII characters are supported in passwords. In earlier versions of vCenter Single Sign-On, limitations on supported characters exist.

Note:
The password policy picks up the maximum length value only if the minimum length is greater than 20 characters. The behavior of the password policy is undefined or could result in failure of services when the minimum length value is greater than 20 characters and the maximum length is set to any value. To avoid a potential problem, leave the minimum length set to the default value of 8 characters, or no greater than 20 characters.

7. Click **Save**.

Edit the vCenter Single Sign-On Lockout Policy

If a user attempts to log in with incorrect credentials, a vCenter Single Sign-On lockout policy specifies when the user's vCenter Single Sign-On account is locked. Administrators can edit the lockout policy.

If a user logs in to vsphere.local multiple times with the wrong password, the user is locked out. The lockout policy allows administrators to specify the maximum number of failed login attempts, and set the time interval between failures. The policy also specifies how much time must elapse before the account is automatically unlocked.

Note:
The lockout policy applies only to user accounts, not to system accounts such as administrator@vsphere.local.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the Configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Configuration**.
4. Click the **Local Accounts** tab.
5. Click **Edit** for the **Lockout Policy** row.

   You might need to scroll down to see the **Lockout Policy** row.
6. Edit the parameters.

Option	Description
Description	Optional description of the lockout policy.
Maximum number of failed login attempts	Maximum number of failed login attempts that are allowed before the account is locked.
Time interval between failures	Time period in which failed login attempts must occur to trigger a lockout.
Unlock time	Amount of time that the account remains locked. If you enter 0, the administrator must unlock the account explicitly.

7. Click **Save**.

Edit the vCenter Single Sign-On Token Policy

The vCenter Single Sign-On token policy specifies token properties such as the clock tolerance and renewal count. You can edit the token policy to ensure that the token specification conforms to security standards in your corporation.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.

3. Navigate to the Configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Configuration**.
4. Click the **Local Accounts** tab.
5. Click **Edit** for the **Token Trustworthiness** row.
   You might need to scroll down to see the **Token Trustworthiness** row.
6. Edit the token policy configuration parameters.

Option	Description
Clock Tolerance	Time difference, in milliseconds, that vCenter Single Sign-On tolerates between a client clock and the domain controller clock. If the time difference is greater than the specified value, vCenter Single Sign-On declares the token invalid.
Maximum Token Renewal Count	Maximum number of times that a token can be renewed. After the maximum number of renewal attempts, a new security token is required.
Maximum Token Delegation Count	Holder-of-key tokens can be delegated to services in the vSphere environment. A service that uses a delegated token performs the service on behalf of the principal that provided the token. A token request specifies a DelegateTo identity. The DelegateTo value can either be a solution token or a reference to a solution token. This value specifies how many times a single holder-of-key token can be delegated.
Maximum Bearer Token Lifetime	Bearer tokens provide authentication based only on possession of the token. Bearer tokens are intended for short-term, single-operation use. A bearer token does not verify the identity of the user or entity that is sending the request. This value specifies the lifetime value of a bearer token before the token has to be reissued.
Maximum Holder-of-Key Token Lifetime	Holder-of-key tokens provide authentication based on security artifacts that are embedded in the token. Holder-of-key tokens can be used for delegation. A client can obtain a holder-of-key token and delegate that token to another entity. The token contains the claims to identify the originator and the delegate. In the vSphere environment, a vCenter system obtains delegated tokens on a user's behalf and uses those tokens to perform operations. This value determines the lifetime of a holder-of-key token before the token is marked invalid.

7. Click **Save**.

Managing vCenter Single Sign-On Users and Groups

A vCenter Single Sign-On administrator user can manage users and groups in the vsphere.local domain from the vSphere Client.

The vSphere Client presents a view of users and groups in your vSphere domain (vsphere.local by default). From this view, you can add, edit, and deactivate users. You can also add groups, and manage group membership.

Add vCenter Single Sign-On Users

Users listed on the **Users** tab in the vSphere Client are internal to vCenter Single Sign-On and belong to the vsphere.local domain. You add users to that domain from one of the vCenter Single Sign-On management interfaces.

You can select other domains and view information about the users in those domains, but you cannot add users to other domains from a vCenter Single Sign-On management interface.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the vCenter Single Sign-On user configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Users and Groups**.
4. If vsphere.local is not the currently selected domain, select it from the drop-down menu.

   You cannot add users to other domains.
5. On the **Users** tab, click **Add**.
6. Enter a user name and password for the new user.

   The maximum number of characters allowed for the user name is 300.

   You cannot change the user name after you create a user. The password must meet the password policy requirements for the system.
7. Optional: Enter the first name and the last name of the new user.
8. Optional: Enter an email address and description for the user.
9. Click **Add**.

When you add a user, that user initially has no privileges to perform management operations.
Add the user to a group in the vsphere.local domain, for example, to the group of users who can administer VMCA (CAAdmins) or to the group of users who can administer vCenter Single Sign-On (Administrators). See Add Members to a vCenter Single Sign-On Group.

Deactivate and Activate vCenter Single Sign-On Users

When a vCenter Single Sign-On user account is deactivated, the user cannot log in to the vCenter Single Sign-On server until an administrator activates the account. You can deactivate and activate accounts from one of the vCenter Single Sign-On management interfaces.

You must be a member of the vCenter Single Sign-On Administrators group to deactivate and activate vCenter Single Sign-On users.

Deactivated user accounts remain available in the vCenter Single Sign-On system, but the user cannot log in or perform operations on the server. Users with administrator privileges can deactivate and activate accounts from the vCenter **Users and Groups** page.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.

3. Navigate to the vCenter Single Sign-On user configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Users and Groups**.
4. Select a user name, click **More**, and click **Disable**.
5. Click **OK**.
6. To activate the user again, click **More**, click **Enable**, and click **OK**.

Delete a vCenter Single Sign-On User

You can delete users that are in the vsphere.local domain from a vCenter Single Sign-On management interface. You cannot delete local operating system users or users in another domain from a vCenter Single Sign-On management interface.

> **CAUTION:**
> If you delete the administrator user in the vsphere.local domain, you can no longer log in to vCenter Single Sign-On. Reinstall vCenter and its components.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.
   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the vCenter Single Sign-On user configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Users and Groups**.
4. Select **Users**, and select the vsphere.local domain from the drop-down menu.
5. In the list of users, select the user that you want to delete.
6. Click **Delete**.
   Proceed with caution. You cannot undo this action.
7. Click **Remove**.

Edit a vCenter Single Sign-On User

You can change the password or other details of a vCenter Single Sign-On user from a vCenter Single Sign-On management interface. You cannot rename users in the vsphere.local domain. That means you cannot rename administrator@vsphere.local.

You can create additional users with the same privileges as administrator@vsphere.local.

vCenter Single Sign-On users are stored in the vCenter Single Sign-On vsphere.local domain.

You can review the vCenter Single Sign-On password policies from the vSphere Client. Log in as administrator@vsphere.local and from the **Administration** menu, select **Configuration** > **Local Accounts** > **Password Policy**.

See also Edit the vCenter Single Sign-On Password Policy.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.
   If you specified a different domain during installation, log in as administrator@*mydomain*.

3. Navigate to the vCenter Single Sign-On user configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Users and Groups**.
4. Click **Users**.
5. Select the user and click **Edit**.
6. Edit the user attributes.
   You cannot change the user name of the user.
   The password must meet the password policy requirements for the system.
7. Click **Save**.

Add a vCenter Single Sign-On Group

The vCenter Single Sign-On**Groups** tab shows groups in the local domain, vsphere.local by default. You add groups if you need a container for group members (principals).

You cannot add groups to other domains, for example, the Active Directory domain, from the vCenter Single Sign-On**Groups** tab.

If you do not add an identity source to vCenter Single Sign-On, creating groups and adding users can help you organize the local domain.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.
   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the vCenter Single Sign-On user configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Users and Groups**.
4. Select **Groups** and click **Create Group**.
5. Enter a name and description for the group.
   The maximum number of characters allowed for the group name is 300. You cannot change the group name after you create the group.
6. From the **Add Members** drop-down menu, select the identity source that contains the member to add to the group.
   If you have configured an external identity provider such as AD FS, the domain of that identity provider is available to select in the **Add Members** drop-down menu.
7. Enter a search term.
8. Select the member.
   You can add more than one member.
9. Click **Done**.

See Add Members to a vCenter Single Sign-On Group.

Add Members to a vCenter Single Sign-On Group

Members of a vCenter Single Sign-On group can be users or other groups from one or more identity sources. You can add new members from the vSphere Client.

See the knowledge base article at https://knowledge.broadcom.com/external/article?legacyId=2095342 for the background information.

Groups listed on the **Groups** tab in the web interface are part of the vsphere.local domain. See Groups in the vCenter Single Sign-On Domain.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the vCenter Single Sign-On user configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Users and Groups**.
4. Click **Groups** and click the group (for example, Administrators).
5. Click **Edit**.
6. From the **Domain** drop-down menu, select the identity source that contains the member to add to the group.

   If you have configured an external identity provider, such as AD FS, the domain of that identity provider is available to select in the **Domain** drop-down menu.
7. Enter a search term.
8. Select the member.

   You can add more than one member.
9. Click **Save**.

Remove Members from a vCenter Single Sign-On Group

You can remove members from a vCenter Single Sign-On group by using the vSphere Client. When you remove a member (user or group) from a group, you do not delete the member from the system.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*mydomain*.
3. Navigate to the vCenter Single Sign-On user configuration UI.
   a) From the **Home** menu, select **Administration**.
   b) Under **Single Sign On**, click **Users and Groups**.
4. Click **Groups** and select a group.
5. Click **Edit**.
6. In the Current members list, click the user or group that you want to remove.
7. Click **Done**.

The user or group is removed from the group, but is still available in the system.

Change Your vCenter Single Sign-On Password

Users in the local domain, vsphere.local by default, can change their vCenter Single Sign-On passwords from the vSphere Client. Users in other domains change their passwords following the rules for that domain.

The vCenter Single Sign-On lockout policy determines when your password expires. By default, vCenter Single Sign-On passwords expire after 90 days, but administrator passwords such as the password for administrator@vsphere.local do not expire. vCenter Single Sign-On management interfaces show a warning when your password is about to expire.

Note:
You can change a password only if it is not expired.

If the password is expired, the administrator of the local domain, administrator@vsphere.local by default, can reset the password by using the `dir-cli password reset` command. Only members of the Administrator group for the vCenter Single Sign-On domain can reset passwords.

1. Log in with the vSphere Client to the vCenter.
2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@*`mydomain`*.
3. In the upper navigation pane, click your user name to pull down the menu and select **Change Password**.
4. Enter your current password.
5. Enter a new password and confirm it.

   The password must conform to the password policy.
6. Click **Confirm**.

   As an alternative, you can select **Single Sign On** > **Users and Groups**, select the user, and click **Edit**.

Managing the Login Message to the vSphere Client Login Page

You can create a message that is displayed on the vSphere Client login page.

You can set a message, disclaimer, or terms and conditions. Also, you can configure the message to require acknowledgment of the message before login.

Manage the Login Message to the vSphere Client Login Page

You can add a login message to the vSphere Client login page. You can also configure a custom login message and provide a check box for user consent.

1. Log in to the vSphere Client.

   Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group. If you specified a different domain during installation, log in as administrator@mydomain.
2. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Administration**.
3. Under **Single Sign On**, click **Configuration**.
4. Click the **Login Message** tab.
5. Click **Edit** and configure the login message.

Option	Description
Show login message	Toggle on **Show login message** to enable the login message. You cannot make changes to the login message unless you toggle on this switch.
Login message	Title of the message. By default, when **Consent checkbox** is toggled on, the login message text is `I agree to Terms and Conditions`. You must replace `Terms and Conditions` with your own text. If the **Consent checkbox** is toggled off, then `Login message` appears, over which you enter your message.
Consent checkbox	Toggle on **Consent checkbox** to require that the user clicks a check box before logging in. You can also display a message without a check box.
Details of login message	Message that the user sees when clicking the login message, for example, the text of the terms and conditions. You must enter some details in this text box.

6. Click **Save**.

vCenter Single Sign-On Security Best Practices

Follow vCenter Single Sign-On security best practices to protect your vSphere environment.

The vSphere authentication infrastructure enhances the security of your vSphere environment. To make sure that your infrastructure is not compromised, follow these vCenter Single Sign-On best practices.

Check Password Expiration

The default vCenter Single Sign-On password policy has a password lifetime of 90 days. After 90 days, the password expires and you can no longer log in. Check the expiration and refresh passwords in a timely fashion.

Configure Network Time Protocol

Use Network Time Protocol (NTP) to ensure that all systems use the same relative time source (including the relevant localization offset), and that the relative time source can be correlated to an agreed-upon time standard (such as Coordinated Universal Time—UTC). Synchronized systems are essential for vCenter Single Sign-On certificate validity, and for the validity of other vSphere certificates.

NTP also makes it easier to track an intruder in log files. Incorrect time settings can make it difficult to inspect and correlate log files to detect attacks, and can make auditing inaccurate.

See the *vSphere Security* documentation for instructions on configuring time synchronization using NTP.

Troubleshooting vCenter Authentication

The following topics provide a starting point for troubleshooting vCenter authentication problems. Search this documentation center and the Broadcom Knowledge Base system for additional pointers.

Determining the Cause of a Lookup Service Error

vCenter Single Sign-On installation displays an error referring to the vCenter or the vSphere Client.

vCenter and Web Client installers show the error `Could not contact Lookup Service. Please check VM_ssoreg.log....`

This problem has several causes, including unsynchronized clocks on the host machines, firewall blocking, and services that must be started.

1. Verify that the clocks on the host machines running vCenter Single Sign-On, vCenter , and the Web Client are synchronized.
2. View the specific log file found in the error message.

   In the message, system temporary folder refers to `%TEMP%`.
3. Within the log file, search for the following messages.

   The log file contains output from all installation attempts. Locate the last message that shows `Initializing registration provider...`

Message	Cause and solution
`java.net.ConnectException: Connection timed out: connect`	The IP address is incorrect, a firewall is blocking access to vCenter Single Sign-On, or vCenter Single Sign-On is overloaded. Ensure that a firewall is not blocking the vCenter Single Sign-On port (by default 7444). Ensure also that the machine on which vCenter Single Sign-On is installed has adequate free CPU, I/O, and RAM capacity.
`java.net.ConnectException: Connection refused: connect`	The IP address or FQDN is incorrect and the vCenter Single Sign-On service has not started or has started within the past minute.

Message	Cause and solution
	Verify that vCenter Single Sign-On is working by checking the status of vCenter Single Sign-On vmware-sso daemon. Restart the service. If restarting does not correct the problem, see the recovery section of the *vSphere Troubleshooting Guide*.
`Unexpected status code: 404. SSO Server failed during initialization`	Restart vCenter Single Sign-On. If restarting does not correct the problem, see the Recovery section of the *vSphere Troubleshooting Guide*.
The error shown in the UI begins with `Could not connect to vCenter Single Sign-On`	You also see the return code `SslHandshakeFailed`. This error indicates that the provided IP address or FQDN that resolves to vCenter Single Sign-On host was not the address used when you installed vCenter Single Sign-On . In the `VM_ssoreg.log`, find the line that contains the following message. `host name in certificate did not match: <install-configured FQDN or IP> != <A> or <B> or <C>` where A was the FQDN you entered during the vCenter Single Sign-On installation, and B and C are system-generated allowable alternatives. Correct the configuration to use the FQDN on the right of the `!=` sign in the log file. In most cases, use the FQDN that you specified during vCenter Single Sign-On installation. If none of the alternatives are possible in your network configuration, recover your vCenter Single Sign-On SSL configuration.

vCenter Login Fails Because the User Account Is Locked

When you log in to vCenter from the vSphere Client login page, an error indicates that the account is locked.

After several failed attempts, you cannot log in to the vSphere Client using vCenter Single Sign-On. You see the message that your account is locked.

You exceeded the maximum number of failed login attempts.

- If you attempted log in as a user from the system domain (vsphere.local by default), ask your vCenter Single Sign-On administrator to unlock your account. If the lock is set to expire in the lockout policy, you can wait until your account is unlocked. vCenter Single Sign-On administrators can use CLI commands to unlock your account.
- If you log in as a user from an Active Directory or LDAP domain, ask your Active Directory or LDAP administrator to unlock your account.

VMware Directory Service Replication Can Take a Long Time

If your environment includes multiple vCenter instances connected through enhanced linked mode, and if one of the vCenter instances becomes unavailable, your environment continues to function. When the vCenter becomes available again, user data and other information are usually replicated within 30 seconds with partners connected through enhanced linked mode. In certain circumstances, however, replication might take a long time.

In certain situations, for example, when your environment includes multiple vCenter instances in different locations, and you make significant changes while one vCenter is unavailable, you do not see replication across VMware Directory Service instances right away. For example, you do not see a new user that was added to the available vCenter instance in the other instance until replication is complete. Replication might take a long time, depending on your enhanced linked mode topology.

During normal operation, changes to a VMware Directory Service (vmdir) instance in one vCenter instance (node) show up in its direct replication partner within about 30 seconds. Depending on the replication topology, changes in one node might have to propagate through intermediate nodes before they arrive at each vmdir instance in each node. Information that is replicated includes user information, certificate information, license information for virtual machines that are created, cloned, or migrated with VMware vMotion, and more.

When the replication link is broken, for example, because of a network outage or because a node becomes unavailable, changes in the federation do not converge. After the unavailable node is restored, each node tries to catch up with all changes. Eventually, all vmdir instances converge to a consistent state but it might take a while to reach that consistent state if many changes occurred while one node was unavailable.

Your environment functions normally while replication happens. Do not attempt to solve the problem unless it persists for over an hour.

Export a vCenter Support Bundle

You can export a support bundle that contains the log files for the vCenter services from the vSphere Client, or by using an API. After the export, you can explore the logs locally or send the bundle to VMware Support.

Verify that the vCenter is successfully deployed and running.

For more information about the API, see *vCenter Management Programming Guide*.

1. From a Web browser, connect to the vCenter configuration management interface at https://*vcenter_server_ip*:5480.
2. Log in as the root user for the vCenter.
3. From the **Actions** menu, select **Create Support Bundle**.
4. Unless browser settings prevent an immediate download, the support bundle is saved to your local machine.

vCenter Authentication Services Logs Reference

The vCenter authentication services use syslog for logging. You can examine the log files to determine the reasons for failures.

Table 90: vCenter Authentication Services Logs

Service	Description
VMware Directory Service	By default, vmdir logging goes to `/var/log/messages` or `/var/log/vmware/vmdird/`. For issues at deployment time, `/var/log/vmware/vmdir/vmafdvmdirclient.log` might also contain useful troubleshooting data.
VMware Single Sign-On	vCenter Single Sign-On logging goes to `/var/log/vmware/sso/`.
VMWare Certificate Authority (VMCA)	VMCA service log is located in `/var/log/vmware/vmcad/vmcad-syslog.log`.
VMware Endpoint Certificate Store (VECS)	VECS service log is located in `/var/log/vmware/vmafdd/vmafdd-syslog.log`.
VMware Lookup Service	Lookup service log is located in `/var/log/vmware/sso/lookupServer.log`.

vCenter and Host Management

Learn how to use the VMware®vSphere Client components, configure and manage hosts, and migrate virtual machines in your vCenter environment.

vCenter and Host Management also provides brief introductions to the various tasks you can perform within the system, and it cross-references to the documentation that describes the tasks in detail.

vCenter and Host Management covers ESX and vCenter.

At VMware, we value inclusion. To foster this principle within our customer, partner, and internal community, we create content using inclusive language.

Intended Audience

vCenter and Host Management is intended for system administrators who are experienced Windows or Linux system administrators and who are familiar with virtual machine technology and data center operations.

What Are the Main vSphere Concepts and Features

VMware vSphere® uses the power of virtualization to transform data centers into simplified cloud computing infrastructures, enabling IT organizations to deliver flexible and reliable IT services.

The two core components of vSphere are VMware ESX™ and VMware vCenter®. ESX is the hypervisor on which you create and run virtual machines. vCenter is a service that acts as a central administrator for ESX hosts that are connected on a network. With vCenter, you can pool and manage the resources of multiple hosts. vCenter allows you to monitor and manage your physical and virtual infrastructure.

Some vSphere components are available as plug-ins that extend the functionality of the vSphere product.

What Are the Basics of Virtualization

A virtual machine is a software computer that, like a physical computer, runs an operating system and applications. ESX is the hypervisor in a vSphere environment. The hypervisor serves as a platform for running virtual machines and allows for the consolidation of computing resources.

Each virtual machine contains its own virtual, or software-based, hardware, including a virtual CPU, memory, hard disk, and network interface card.

ESX is installed on physical hardware in a virtualized data center, and acts as a platform for virtual machines. The hypervisor provides physical hardware resources dynamically to virtual machines to support the operation of the virtual machines. The hypervisor allows virtual machines to operate with a degree of independence from the underlying physical hardware. For example, a virtual machine can be moved from one physical host to another, or its virtual disks can be moved from one type of storage to another, without affecting the functioning of the virtual machine.

Because virtual machines are decoupled from the underlying physical hardware, virtualization allows you to consolidate physical computing resources such as CPUs, memory, storage, and networking into pools of resources. These resources can be dynamically and flexibly made available to virtual machines. With the vCenter management platform, you can increase the availability and security of your virtual infrastructure.

What Is the Physical Topology of a vSphere Data Center

A typical VMware vSphere data center consists of physical building blocks such as x86 virtualization servers, storage networks and arrays, IP networks, a management server, and desktop clients.

The vSphere data center includes the following components.

ESX Hosts	Industry standard x86 servers that run ESX on the bare metal. ESX software provides resources for and runs the virtual machines. You can group similarly configured x86 servers with connections to the same network and storage subsystems. This grouping creates an aggregate set of resources in the virtual environment, called a cluster.

Storage networks and arrays	VMware vSphere uses Fibre Channel SAN arrays, iSCSI SAN arrays, and NAS arrays to meet different data center storage needs. With storage area networks, you can connect and share storage arrays between groups of servers. This arrangement allows aggregation of the storage resources and provides more flexibility in provisioning them to virtual machines. For detailed information, see *vSphere Storage*.
IP networks	Each compute server can have multiple physical network adapters to provide high bandwidth and reliable networking to the entire VMware vSphere data center. For detailed information, see *vSphere Networking*.
vCenter	vCenter provides a single point of control to the data center. It provides essential data center services such as access control, performance monitoring, and configuration. It unifies the resources from the individual computing servers to be shared among virtual machines in the entire data center. It manages the assignment of virtual machines to the ESX hosts and the assignment of resources to the virtual machines within a given computing server. These assignments are based on the policies that the system administrator sets. Compute servers continue to function even if vCenter becomes unreachable (for example, if the network is severed). The ESX hosts can be managed separately and continue to run the virtual machines assigned to them based on the resource assignment that was last set. After connection to vCenter is restored, it can manage the data center as a whole again.
Management clients	VMware vSphere provides several interfaces for data center management and virtual machine access. These interfaces include vSphere Client for access through a web browser or vSphere Command-Line Interface (vSphere CLI).

What Are the Software Components of vSphere

VMware vSphere is a suite of software components for virtualization. These include ESX, vCenter, and other software components such as vCenter Single Sign-On, and vCenter plug-ins that fulfill several different functions in the vSphere environment.

vSphere includes the following software components:

ESX	The hypervisor runs virtual machines. Each virtual machine has a set of configuration and disk files that together perform all the functions of a physical machine. Through ESX, you run the virtual machines, install operating systems, run applications, and configure the virtual machines. Configuration includes identifying the virtual machine's resources, such as storage devices. The server provides bootstrapping, management, and other services that manage your virtual machines.
vCenter	A service that acts as a central administrator for VMware ESX hosts that are connected on a network. vCenter directs actions on the virtual machines and the ESX hosts. vCenter is installed to run automatically on a preconfigured virtual machine. The vCenter service runs continuously in the background. It performs its monitoring and managing activities even when no vSphere Clients are connected and when no one is logged on to the computer where it resides. It must have network access to all the hosts it manages. vCenter is deployed as a preconfigured virtual machine optimized for running vCenter and the vCenter components. You can deploy vCenter on ESX hosts 6.5 or later. All prerequisite services for running vCenter and the vCenter components are bundled in the vCenter installation. All vCenter services run as child processes of the VMware Service Library Lifecycle Manager service. See the *vCenter Installation and Setup* documentation for details about setting up this configuration.
vCenter Single Sign-On	A service that is part of the vCenter management infrastructure. The vCenter Single Sign-On authentication service makes the VMware Cloud infrastructure platform more secure by allowing the various vSphere software components to communicate with each other. The vCenter Single Sign-On authentication service uses a secure token exchange mechanism instead of requiring each component to authenticate a user separately with a directory service like Active Directory. For more information, see Configure VMware Single Sign-On.
vCenter plug-ins	Applications that provide additional features and functionality to vCenter. Typically, plug-ins consist of a server component and a client component. After the plug-in server is installed, it is registered with vCenter and the plug-in client is available to the vSphere Client for download. After a plug-in is installed on the vSphere Client, it might alter the interface by adding views, tabs, toolbar buttons, or menu items related to the added functionality.

	Plug-ins leverage core vCenter capabilities, such as authentication and permission management, but can have their own types of events, tasks, metadata, and privileges. Some vCenter features are implemented as plug-ins, and can be managed using the vSphere Client Plug-in Manager. These features include vCenter Storage Monitoring, vCenter Hardware Status, and vCenter Service Status.
vCenter database	Persistent storage for maintaining the status of each virtual machine, host, and user managed in the vCenter environment. The vCenter database can be remote or local to the vCenter system. The database is installed and configured during vCenter installation. If you are accessing your ESX host directly through the VMware Host Client, and not through a vCenter system and associated vSphere Client, you do not use a vCenter database.
tcServer	Many vCenter functions are implemented as web services that require the tcServer. The tcServer is installed on the vCenter machine as part of the vCenter installation. Features that require the tcServer to be running include: ICIM/Hardware Status tab, Performance charts, WebAccess, Storage Policy-Based services, and vCenter Service status.
vCenter agent	On each managed host, the software that collects, communicates, and runs the actions received from vCenter. The vCenter agent is installed the first time any host is added to the vCenter inventory.
Host agent	On each managed host, the software that collects, communicates, and runs the actions received through the vSphere Client. It is installed as part of the ESX installation.

What Are the Client Interfaces for vSphere

You can access vSphere components through the vSphere Client, the VMware Host Client, and the vSphere Command-Line Interfaces.

vSphere Client	The vSphere Client, introduced in vSphere 6.5, is an HTML5-based client and is included with vCenter. The vSphere Client is the primary interface for connecting to and managing vCenter instances.
VMware Host Client	The VMware Host Client is a Web-based application that you can use to manage individual ESX hosts that are not connected to a vCenter system. For more information about the VMware Host Client, see *vSphere Single Host Management - VMware Host Client*.
vSphere Command-Line Interfaces	vSphere supports multiple command-line interfaces for configuring virtual machines, ESX hosts, and vCenter.

What Are the Managed Inventory Objects in vSphere

In vSphere, the inventory is a collection of virtual and physical objects, such as data centers, networks, and datastores, on which you can place permissions, monitor tasks and events, and set alarms. You can rename inventory objects, and you can group most inventory objects by using folders to more easily manage them.

All inventory objects, with the exception of hosts, can be renamed to represent their purposes. For example, they can be named after company departments or locations or functions.

Note:
Managed object names cannot exceed 214 bytes (UTF-8 encoded).

vCenter monitors and manages the following inventory objects:

Data Centers	Unlike folders, which are used to organize specific object types, a data center is an aggregation of all the different types of objects used to work in virtual infrastructure. Within each data center, there are four separate hierarchies. • Virtual machines (and templates) • Hosts (and clusters) • Networks • Datastores The data center defines the namespace for networks and datastores. The names for these objects must be unique within a data center. You cannot have two datastores with the same name within a single

	data center, but you can have two datastores with the same name in two different data centers. Virtual machines, templates, and clusters need not be unique within the data center, but must be unique within their folder. Objects with the same name in two different data centers are not necessarily the same object. Because of this, moving objects between data centers can create unpredictable results. For example, a network named networkA in data_centerA might not be the same network as a network named networkA in data_centerB. Moving a virtual machine connected to networkA from data_centerA to data_centerB results in the virtual machine changing the network it is connected to.
Clusters	A collection of ESX hosts and associated virtual machines intended to work together as a unit. When you add a host to a cluster, the host's resources become part of the cluster's resources. vCenter manages the resources of all hosts in a cluster as one unit. If you enable VMware EVC on a cluster, you can ensure that migrations with vMotion do not fail because of CPU compatibility errors. If you enable vSphere DRS on a cluster, the resources of the hosts in the cluster are merged to allow resource balancing for the hosts in the cluster. If you enable vSphere HA on a cluster, the resources of the cluster are managed as a pool of capacity to allow rapid recovery from host hardware failures.
Datastores	A virtual representation of physical storage resources in the data center. A datastore is the storage location for virtual machine files. In an on-premises SDDC, these physical storage resources can come from the local SCSI disk of the ESX host, the Fibre Channel SAN disk arrays, the iSCSI SAN disk arrays, or Network Attached Storage (NAS) arrays. For both on-premises and cloud SDDCs, vSAN datastores hide the idiosyncrasies of the underlying physical storage and present a uniform model for the storage resources required by virtual machines.
Folders	Folders allow you to group objects of the same type so you can easily manage them. For example, you can use folders to set permissions across objects, to set alarms across objects, and to organize objects in a meaningful way. A folder can contain other folders, or a group of objects of the same type: data centers, clusters, datastores, networks, virtual machines, templates, or hosts. For example, one folder can contain hosts and a folder containing hosts, but it cannot contain hosts and a folder containing virtual machines. Data center folders form a hierarchy directly under the root vCenter and allow users to group their data centers. Within each data center is one hierarchy of folders with virtual machines and templates, one with hosts and clusters, one with datastores, and one with networks.
Hosts	The physical computer on which ESX is installed. All virtual machines run on hosts or clusters.
Networks	A set of virtual network interface cards (virtual NICs), distributed switches or vSphere Distributed Switches, and port groups or distributed port groups that connect virtual machines to each other or to the physical network outside of the virtual data center. All virtual machines that connect to the same port group belong to the same network in the virtual environment, even if they are on different physical servers. You can monitor networks and set permissions and alarms on port groups and distributed port groups.
Resource pools	Resource pools are used to compartmentalize the CPU and memory resources of a host or cluster. Virtual machines run in, and draw their resources from, resource pools. You can create multiple resource pools as direct children of a standalone host or cluster and then delegate control over each resource pool to other individuals or organizations. If DRS is enabled, provides various options for monitoring the status of the resources and adjusting or suggesting adjustments to the virtual machines using the resources. You can monitor resources and set alarms on them.
Templates	A template is a primary copy of a virtual machine that can be used to create and provision new virtual machines. Templates can have a guest operating system and application software installed. They can be customized during deployment to ensure that the new virtual machine has a unique name and network settings.
Virtual machines	A virtualized computer environment in which a guest operating system and associated application software can run. Multiple virtual machines can operate on the same managed host machine concurrently.
vApps	vSphere vApp is a format for packaging and managing applications. A vApp can contain multiple virtual machines.
Virtual Private Clouds (VPC) and subnets	Starting with VCF 9.0, VCP instances and subnets are available as inventory objects integrated from NSX. VPC is an industry standard for networking consumption. You can create a VPC instance and the underlying subnets, and attach virtual machines to the subnets directly from the vSphere Client, or through vCenter API or CLI. VPC instances that are created by using the NSX Manager are visible in the vCenter inventory tree. VPC instances that are created by using vCenter APIs or the vSphere Client are available in the NSX Manager.

Advanced vCenter Components

vCenter has several components that are packaged and installed with the base product.

vCenter components include:

VMware vSphere® vMotion®	Enables you to move running virtual machines from one ESX host to another ESX host without service interruption. It requires licensing on both the source and target host. vCenter centrally coordinates all vSphere vMotion activities.
vSphere® Storage vMotion®	Allows you to move the disks and configuration file of a running virtual machine from one datastore to another without service interruption. It requires licensing on the virtual machine's host.
VMware vSphere® High Availability	Enables a cluster with High Availability. If a host fails, all virtual machines that were running on the host are promptly restarted on different hosts in the same cluster. When you enable the cluster for vSphere HA, you specify the number of hosts you want to be able to recover. If you specify the number of host failures allowed as **1**, vSphere HA maintains enough capacity across the cluster to tolerate the failure of one host. All running virtual machines on that host can be restarted on remaining hosts. By default, you cannot turn on a virtual machine if doing so violates required failover capacity.
VMware vSphere® Distributed Resource Scheduler ™	Helps improve resource allocation and power consumption across all hosts and resource pools. vSphere DRS collects resource use information for all hosts and virtual machines in the cluster and gives recommendations (or migrates virtual machines) in one of two situations: • Initial placement – When you power on a virtual machine in the cluster for the first time, DRS either places the virtual machine or makes a recommendation. • Load balancing – DRS attempts to improve resource use across the cluster by performing automatic migrations of virtual machines (vSphere vMotion) or by providing a recommendation for virtual machine migrations. vSphere DRS includes VMware vSphere®Distributed Power Management ™ (DPM) capabilities. When DPM is enabled, the system compares cluster-level and host-level capacity to the demands of virtual machines that are running in the cluster. Based on the results of the comparison, DPM recommends (or implements) actions that can reduce the power consumption of the cluster.
VMware vSphere® Storage DRS™	Allows you to manage multiple datastores as a single resource, called a datastore cluster. A datastore cluster is an aggregation of multiple datastores into a single logical, load-balanced pool. You can treat the datastore cluster as a single flexible storage resource for resource management purposes. You can assign a virtual disk to a datastore cluster, and vSphere Storage DRS finds an appropriate datastore for it. The load balancer takes care of initial placement and future migrations based on workload measurements. Storage space balancing and I/O balancing minimize the risk of running out of space and the risk of I/O bottlenecks slowing the performance of virtual machines.
VMware vSphere® Fault Tolerance	vSphere Fault Tolerance provides continuous availability for virtual machines by creating and maintaining a Secondary VM that is identical to the Primary VM. This Secondary VM is continuously available to replace the Primary VM in a failover situation.

vCenter Plug-Ins

vCenter plug-ins extend the capabilities of vCenter by providing additional features and functions.

Some plug-ins are installed as part of the base vCenter product.

vCenter Storage Monitoring	Allows you to review information on storage use and to map relationships visually between all storage entities available in vCenter.
vCenter Hardware Status	Uses CIM monitoring to display the hardware status of hosts that vCenter manages.
vCenter Service Status	Displays the status of vCenter services.

Some plug-ins are packaged separately from the base product and require separate installation. You can update plug-ins and the base product independently of each other. VMware modules include:

vSphere Lifecycle Manager	Enables administrators to apply updates and patches across ESX hosts and all managed virtual machines. Administrators can create user-defined security baselines that represent a set of security standards. Security administrators can compare hosts and virtual machines against these baselines to identify and remediate systems that are not in compliance.

VMware Cloud Foundation Operations orchestrator	A workflow engine that enables you to create and run automated workflows in your vSphere environment. VMware Cloud Foundation Operations orchestrator coordinates workflow tasks across multiple VMware products and third-party management and administration solutions through its open plug-in architecture. VMware Cloud Foundation Operations orchestrator provides a library of workflows that are extensible. You can use any operation available in the vCenter API to customize VMware Cloud Foundation Operations orchestrator workflows.

Using the vSphere Client

Use the vSphere Client to connect to vCenter systems and manage vSphere inventory objects.

Use of the vSphere Client requires a supported web browser.

The home screen of the vSphere Client is a system dashboard that aggregates data from different sources in the environment together in a single, unified view.

VMware has tested and supports the following guest operating systems and browser versions for the vSphere Client.

Table 91: Supported Guest Operating Systems and Browser Versions for the vSphere Client.

Operating system	Browser
Windows 32-bit and 64-bit	Microsoft Edge: 120 and later. Mozilla Firefox: 115 and later. Google Chrome: 120 and later.
Mac OS	Microsoft Edge: 120 and later. Mozilla Firefox: 115 and later. Google Chrome: 120 and later.

Earlier versions of these browsers are likely to work, but have not been tested.

How to Use and Configure Your vSphere Client

Learn how to configure the vSphere Client timeout settings, edit the login banner, and refresh data in the vSphere Client.

Manage the Login Message to the vSphere Client Login Page

You can add a login message to the vSphere Client login page. You can also configure a custom login message and provide a check box for user consent.

1. Log in to the vSphere Client.

   Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group. If you specified a different domain during installation, log in as administrator@mydomain.
2. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Administration**.
3. Under **Single Sign On**, click **Configuration**.
4. Click the **Login Message** tab.
5. Click **Edit** and configure the login message.

Option	Description
Show login message	Toggle on **Show login message** to enable the login message. You cannot make changes to the login message unless you toggle on this switch.
Login message	Title of the message. By default, when **Consent checkbox** is toggled on, the login message text is `I agree to Terms and Conditions`. You must replace `Terms`

Option	Description
	`and Conditions` with your own text. If the **Consent checkbox** is toggled off, then `Login message` appears, over which you enter your message.
Consent checkbox	Toggle on **Consent checkbox** to require that the user clicks a check box before logging in. You can also display a message without a check box.
Details of login message	Message that the user sees when clicking the login message, for example, the text of the terms and conditions. You must enter some details in this text box.

6. Click **Save**.

How to Configure Your vSphere Client Timeout Value

By default, the vSphere Client sessions close after 120 minutes of idle time, and require the user to log in again to resume using the client.

Change the Client Configuration in the vSphere Client

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Administration**.
2. Under **Deployment**, select **Client Configuration**.
3. In the **Client Configuration** pane, click **Edit**.
   The **Edit client configuration** dialog box appears.
4. Enter a new value in minutes in the session timeout text box.
5. Click **Save**.
6. Restart the VMware vSphere Client service.
   - Enables SSH access to vCenter, and use this Bash shell command `service-control --restart vsphere-ui`.
   - Use the Center Appliance Management Interface (VAMI).
     a. In a web browser, go to the vCenter Appliance Management Interface, https://**vcenter-IP-address-or-FQDN**:5480.
     b. Log in with the root user credentials.
     c. In the left navigation pane, click **Services**.
     d. From the list of services, select VMware vSphere Client, and click **Restart**.

How Do You Refresh Data in the vSphere Client

You must manually refresh the data in the vSphere Client to see changes made to objects by other users during your session.

For performance reasons, the vSphere Client does not continuously refresh data on all objects in the inventory. All changes that you make during your current session are immediately reflected in the client user interface. Changes made by other users or in other sessions are not reflected until you manually refresh the data.

To update all data in the current vSphere Client view, click the refresh icon ( ).

The client view is updated.

How to Use Your vSphere Client Inventory

Learn how to navigate, search, and sort the vSphere Client inventory.

How to Use Your Global Inventory Lists Navigator

You can use the vSphere **Global Inventory Lists** navigator to browse and select objects in the vSphere inventory as an alternative to the hierarchical inventory tree.

Unlike the inventory tree, which presents hierarchical arrangements of parent and child objects arranged in the **Hosts and Clusters**, **VMs and Templates**, **Storage**, and **Networking** inventory lists, the Global Inventory Lists navigator presents a list of all related objects in the inventory. You can navigate from an object to its related objects, regardless of their type.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Global Inventory Lists**.
2. In the left pane, select one of the object or resource categories to view objects of that type.
   For example, click **Hosts** to view the hosts in the vSphere inventory.
3. In the left navigation pane, click an object from the list once to display information about the object.
4. Optional: Click the object again to open it.

   Opening an object brings it to the top of the navigator and displays related object categories beneath it.

   For example, opening a host allows you to see the child resource pools, virtual machines, datastores, networks, and distributed switches associated with this host.
5. To access additional information or manage the selected object, click one of the tabs in the center pane.

Option	Description
Summary	You can view basic status and configuration for an object.
Monitor	You can view alarms, performance data, resource allocation, events, and other status information for an object.
Configure	Depending on the selected object, you can edit settings, alarm definitions, tags, permissions, and so on.
Permissions	You can view, add, change, and delete permissions. This tab is only available for logged in users with administration privileges.
Related Objects tabs	You can view and manage the objects related to the object that you selected. For example, if you select a host, the tabs that you see are **VMs**, **Resource Pools**, **Datastores**, and **Networks**.
Updates	Depending on the selected object, you can check the hardware compatibility of a host against the VMware Compatibility Guide, check the status of virtual machines, upgrade the VMware Tools version or the virtual hardware version of the virtual machines, and perform vSphere Lifecycle Manager operations. **Note:** The **Updates** tab is available only for certain types of inventory objects, for example, hosts, virtual machines, and clusters.

Inventory Keyboard Shortcuts in the vSphere Client

Discover some of the inventory keyboard shortcuts that you can use to quickly navigate to different inventories in the vSphere Client.

Table 92: Inventory Keyboard Shortcuts

Keyboard Combination on a Windows machine	Keyboard Combination on a Mac machine	Action
Ctrl+Alt+Home	Control+Option+Home	Home
Ctrl+Alt+1	Control+Option+1	Shortcuts
Ctrl+Alt+2	Control+Option+2	Hosts and Clusters

Keyboard Combination on a Windows machine	Keyboard Combination on a Mac machine	Action
Ctrl+Alt+3	Control+Option+3	VMs and Templates
Ctrl+Alt+4	Control+Option+4	Storage
Ctrl+Alt+5	Control+Option+5	Networking
Ctrl+Alt+6	Control+Option+6	Content Libraries
Ctrl+Alt+7	Control+Option+7	Supervisor Management
Ctrl+Alt+8	Control+Option+8	Global Inventory Lists
Ctrl+Alt+R	Control+Option+R	Refresh
Ctrl+Alt+S repeat twice	Control+Option+S repeat twice	Search

How to Sort Your vSphere Client Inventory Objects

You can use sortable columns and input filters to sort and find objects in your vSphere Client inventory that meet certain criteria.

You can sort list views by column. These list views can be selected in the **Global Inventory Lists** pane or found in search results.

For example, you can sort virtual machines by name, provisioned space, used space, and so on.

1. In the vSphere Client, click the main navigation menu
   (**),**
   and select **Global Inventory Lists**.
2. To open an object list view, select an object type from the list.
   If objects from the selected type are not present in the inventory, a blank page appears.
3. Optional: Click the column you want to sort objects by. You can click again on that column to reverse the sorting order.
4. Add or remove columns from the object list view:
   a) Click **Manage Columns** at the bottom left corner of the object list view.
      The **Show Columns** pop-up appears.
   b) Optional: To show a column in the object list view, select the check box for the column from the list.
   c) Optional: To hide a column from the object list view, deselect the check box for the column from the list.

How to Use Quick Filters to Find Objects in Your vSphere Client Inventory

From a list view, you can use the quick filter field to filter objects by entering specific values.

You can use input filters to sort and find objects in your vSphere Client inventory that meet certain criteria. You can filter inventory objects by name, state, status, and so on.

1. In the vSphere Client, click the main navigation menu
   (**),**
   and select **Global Inventory Lists**.
2. To open an object list view, select an object type from the list.
   If objects from the selected type are not present in the inventory, a blank page appears.

3. Click the drop-down menu on top of the inventory object list table, and select **Quick Filter**.
4. Enter your filtering parameter in the empty filter field. For example, in the virtual machine list view, to filter for all virtual machines that are in a powered on state, you must enter `powered on`.

   A list of inventory objects that meet your filtering criteria is displayed in your selected sorting order.

To clear the filtered list of inventory objects, delete the filtering parameter from the filter field.

How to Use Advanced Filters to Find Objects in Your vSphere Client Inventory

You can use the advanced filter options to create a set of filtering criteria and find specific objects in your vSphere Client.

1. In the vSphere Client, click the main navigation menu ( ), and select **Global Inventory Lists**.
2. To open an object list view, select an object type from the list.

   If objects from the selected type are not present in the inventory, a blank page appears.
3. Click the drop-down menu on top of the inventory object list table, and select **Advanced Filter**.
4. Click **Add New**.

   A pop-up window appears.
5. From the drop-down menu under Filter, select the filtering parameter.
6. Depending on the parameter you select, you must select values from a pre-defined list, or enter data in a filter operator.
   - From the Value list, select all values that you want to apply as filtering criteria.
   - From the filter operator, select how the filtering criteria must relate to each other and enter the filter value.

     Note:
     If you want to specify the filtering criteria further, you can click **Add Condition**, and enter the required details for the second filter operator.
7. Click **Apply**.

   A list of inventory objects that meet your filtering criteria is displayed in your selected sorting order. The filters that you apply are displayed on top of the inventory list.

   Note:
   You can apply multiple advanced filters to the inventory list. They are combined with the logical operator *and*.
8. Optional: To edit a filter that you applied, click the filter displayed on top of the inventory list, edit the filtering criteria, and click **Apply**.
9. Optional: To hide all filters applied to the inventory list, click **Hide All**.

   The filters continue to be applied.

To delete a filter that you applied, click the remove icon ( ) next to the filtering criterion. If the filter consists of more than one filtering criteria, you should remove each one separately.

To delete all filters applied to the inventory list, click **Clear All**.

How to Search Your vSphere Client Inventory

With the vSphere Client, you can search the inventory for objects that match specified criteria. You can search the inventories of all vCenter systems.

You can only view and search for inventory objects that you have permission to view.

Note:
If your permissions change while you are logged in, the search service might not immediately recognize these changes. To ensure that your search is performed with up-to-date permissions, log out of all your open sessions and log in again before you perform the search.

Perform a Quick Search

A quick search checks all types of objects for the specified search term within the name or other properties of the object.

1. Enter the search term in the search box at the top of the vSphere Client window.
   Multiple search terms in a quick or simple search are treated as if they are connected by ORs. For example, searching for `example machine` finds all objects with names containing either "example" or "machine".
   The search results appear below the search box as you type. The number of items displayed is limited to 10.
2. To run a saved search, click the saved search icon and select a saved search query.
3. To display an item in the inventory, click the item from the drop-down list of the search results.
4. To see more search results or more details about the search results, click the summary of the search results from the drop-down list of search results.
   a. To display an object in the inventory, click the object in the search results page.
   The search results are listed in tables arranged by object type. For example, if a search finds hosts and virtual machines, the following tables appear: **Hosts**, which shows only host results and **Virtual Machines**, which shows only virtual machine results.

Save a Search

You can save search queries in the vSphere Client so you can rerun, rename, or delete them later.

1. In a vSphere Client window, enter a query for a simple search in the search box.
2. Click the summary of the search results from the drop-down list with search results.
3. On the search results page, click **Save Search**.
4. Enter a name for the search query. Names must be lowercase with no spaces.
5. Click **Save**.
   The search query you entered is saved. You can reload the query later and repeat the search.

Manage a Saved Search

In the vSphere Client, you can rename, delete, or create a duplicate of a saved search query.

1. At the top of the vSphere Client window, click inside the search box.
2. Click the saved search icon and select a saved search query.
3. On the Search Results page, click **Actions** and select one of the options:

Option	Description
Save as	Creates a duplicate of the saved search query.
Rename	Renames the saved search query.
Delete	Deletes the saved search query.

4. Confirm the changes.

How to Export Your vSphere Inventory Lists

In the vSphere Client, you can export the contents of an inventory list view to a CSV file.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select**Global Inventory Lists**.
2. In the left pane, select one of the object or resource categories to view objects of that type.
   For example, click **Hosts** to view the hosts in the vSphere inventory.
3. Select whether you want all columns or your current selection of columns to be listed in the CSV file.
   a) Click **Manage Columns** at the bottom left corner of the object list view.
      The **Show Columns** pop-up appears.
   b) Optional: To show a column in the object list view, select the check box for the column from the list.
   c) Optional: To hide a column from the object list view, deselect the check box for the column from the list.
   d) Optional: To show all columns, click **SELECT ALL**.
4. Click **Export** at the bottom left corner of the list view.

The CSV file is generated and available for download.

How to Manage Your vCenter Client Plug-Ins

Learn how to monitor, add, or remove vCenter client plug-ins. You can monitor client plug-in activities including installation progress, failures, deployments, upgrades, and uninstallations.

From the vSphere Client, you can monitor vCenter client plug-ins using the **Recent Tasks** pane, the **Task Console**, or the **Administration** > **Client Plugins** view. In addition to monitoring installation progress, you can troubleshoot installation failures and plug-in incompatibilities. You can also add and remove client plug-ins.

For more information about how to develop client plug-ins, see the *Developing Remote Plug-ins with the vSphere Client SDK* documentation on https://developer.vmware.com.

View Details about a Client Plug-In

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Administration**.
2. Under **Solutions**, click **Client Plugins**.
   The **Client Plugins** main view shows a list of all deployed client plug-ins. You can view information about the name, version, deployment status, type, certification status, vendor, and plug-in ID of each client plug-in.
3. In the Name column, click a client plug-in name to open the client plug-in details view.
   You can use the client plug-in details view to view more information about the client plug-in instances, control the visibility of the client plug-ins on specific vCenter systems, and remove client plug-ins from the vSphere Client.

Hide and Show a Client Plug-In on a vCenter Instance

If your environment includes several vCenter systems joined in Enhanced Linked Mode, the vSphere Client can load views from client plug-ins added to any of the linked vCenter instances. You configure what is visible in a specific vCenter system, by using the **Hide** and **Show** options from the details view of a selected client plug-in.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Administration**.
2. Under **Solutions**, click **Client Plugins**.
3. From the Name column, click the client plug-in name.

The detailed client plug-in view opens.

4. Change the visibility of a client plug-in instance on a vCenter instance.
   a. Select the check box on the client plug-in instance.
      - To hide a client plug-in in the vSphere Client UI for a vCenter instance, select the check box on the instance version and click **Hide**.
      - To make a client plug-in instance visible in the vSphere Client UI for a vCenter instance, select the client plug-in version and click **Show**.
5. Confirm your choice in the pop-up dialog box that appears.

Add a Client Plug-In with the vSphere Client

Staring with vSphere 8.0, you can deploy remote client plug-ins using the vSphere Client. In an environment with several vCenter instances connected with Enhanced Linked Mode, you can select on which vCenter systems to deploy the client plug-in.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Administration**.
2. Under **Solutions**, click **Client Plugins**.
3. In the **Client Plugins** pane, click **Add**.
   The **Install new solution** wizard opens.
4. On the **Select an OVF template** page, specify the location of the client plug-in OVF descriptor file and click **Next**.

Option	Action
URL	Enter the URL to the OVF descriptor file located on the Internet. The only supported URL sources are HTTPS. **Note:** Make sure that all elements of the client plug-in are at the same location as the OVF descriptor file. Missing files might lead to failure in plug-in deployment.
Local file	Click **Upload files** and select all files associated with the client plug-in.

5. On the **Select a name and folder** page, enter a unique name for the virtual machine, select a deployment location, and click **Next**.
   The default name for the virtual machine is the same as the human-readable name of the plug-in defined in the OVF file. If you change the default name, choose a name that is unique within each vCenter virtual machine folder.
6. On the **Select a compute resource** page, select a resource where to run the deployed client plug-in VM, and click **Next**.
7. On the **Review details** page, verify the client plug-in details and click **Next**.
8. On the **License agreement** page, accept the end-user license agreements and click **Next**.
9. On the **Select storage** page, define where and how the files for the deployed client plug-in are stored.
   – Select a storage policy for the virtual machine.
     This option is available only if storage policies are enabled on the destination resource.
   – Select the **Disable Storage DRS for this virtual machine** check box to deactivate Storage DRS for the virtual machine.
   – Select a datastore to store the deployed client plug-in.
     The plug-in manifest file and virtual disk files are stored on the datastore. Select a datastore large enough to accommodate the virtual machine and all associated virtual disk files.
10. On the **Select networks** page, select a source network and map it to a destination network. Define the IP allocation settings of the client plug-in server. Click **Next**.
    The Source Network column lists all networks as defined in the OVF descriptor file.
11. On the **Customize template** page, view the read-only settings of the client plug-in and click **Next**.

12. On the **Associate vCenter** page, select the vCenter instances on which the client plug-in is deployed and click **Next**.
13. On the **Ready to complete** page, review your selections and click **Finish**.

As a result new tasks for downloading and installing the client plug-in appear in the **Recent Tasks** pane. After successful completion of the tasks, refresh your browser to see the newly added client plug-in.

Remove a Client Plug-In from a vCenter Instance

You can remove a client plug-in from the vSphere Client UI for a vCenter instance. In an environment with several vCenter instances connected with Enhanced Linked Mode, you can select from which vCenter systems to remove the client plug-in.

> **Note:**
>
> When you remove a client plug-in from the vSphere Client UI, the virtual machine on which the client plug-in instance is running is not removed from the vCenter instance. You must delete the virtual machine from the datastore to complete the client plug-in removal.

1. In the vSphere Client, click the main navigation menu ( ), and select **Administration**.
2. Under **Solutions**, click **Client Plugins**.
3. From the Name column in the **Client Plugins** pane, select the client plug-in.
   The detailed client plug-in view opens.
4. Select the check box on one of the client plug-in instances and click **Remove**.
5. In the confirmation dialog box, click **Yes** to remove the client plug-in instance.

As a result, the client plug-in is undeployed from the vCenter instance. Make sure that you refresh your browser to remove the client plug-in from the vSphere Client UI.

How to Start, Stop, and Restart Services in Your vSphere Client

In the vSphere Client, you can start, stop, and restart services that are running on vCenter. You can restart services upon a configuration change or for suspected functional or performance issues.

1. Log in to the vCenter Management Interface at https://<vcenter_fqdn>:5480.
   - Log in to the vCenter Management Interface directly.
   - In the vSphere Client home page, select **Administration** > **System Configuration**. Click a node from the list.
2. On the vCenter Management Interface home page, click **Services**.
3. Select a service from the service list.
4. From the top menu, click **Restart**, **Start**, or **Stop**.
   Unavailable options are dimmed.

   > **Note:**
   > Restarting the Content Library Service also restarts the Transfer Service and the OVF Service. The Content Library Service, the Transfer Service, and the OVF Service run on the same Tomcat server.

How to Provide Feedback in the vSphere Client

Use the feedback tool in the vSphere Client to provide timely feedback to our developers.

1. From the vSphere Client, click the feedback icon in the top-right corner.
2. Select the type of feedback that you want to give, and enter your feedback in the **Description** window.

   If you want to provide ideas for new features, use the VCF Feature Request Portal. For more information, see Use the VCF Feature Requests Portal to Submit vSphere Feature Requests.

3. Optional: Provide an email address and screenshots or other images.
4. Click **Send**.

Use the VCF Feature Requests Portal to Submit vSphere Feature Requests

You can provide suggestions for new vSphere features or share feature requests through the VCF Feature Requests Portal. All users with valid Broadcom Support Portal accounts can access the portal.

Verify that you have a valid Broadcom Support Portal account.

The VCF Feature Requests Portal is public. When you publish new ideas and feature requests, consider whether you want to share personal data.

You can access the VCF Feature Requests Portal at https://vcf.ideas.aha.io/portal_session/new by entering a valid Broadcom Support Portal user name and password.

1. On the VCF Feature Requests Portal login page, use your Broadcom Support Portal credentials to log in.
2. On the VCF Feature Requests Portal home page, click **Add a new idea**.
3. On the **VCF Feature Request Idea Portal Screen** page, in the **Your Idea** text field, enter a summary of your feature idea.
4. Enter a more detailed description of your idea.
5. From the **VCF Product Category** drop-down menu, select the respective vSphere category for which you want to submit an idea.
6. Click **Next**.
7. Optional: In the **Your Details** page, provide your company name and the customer impact of your idea.
8. Click **Next**.
9. Review the summary of your idea and click **Add Idea**.

Your idea appears in the **My Ideas** tab and in the list with submitted ideas. All users of the VCF Feature Requests Portal can view, subscribe, vote, and comment on your idea.

Configuring the Customer Experience Improvement Program

You can participate in the Customer Experience Improvement Program (CEIP) to provide anonymous feedback or information to VMware for quality, reliability, and functionality improvement of VMware products and services.

VMware Customer Experience Improvement Program

vCenter participates in VMware's Customer Experience Improvement Program (CEIP).

Details regarding the data collected through CEIP and the purposes for which it is used by VMware are set forth at the Trust & Assurance Center at https://www.broadcom.com/company/legal/privacy/data-usage-programs/ceip-products.

Join or Leave Customer Experience Improvement Program in vSphere Client

You can join your vCenter to the Customer Experience Improvement Program (CEIP), or decide to leave the CEIP at any time. To leave and rejoin your host to the CEIP, see *vSphere Single Host Management - VMware Host Client* documentation.

Obtain the user name and password of the administrator account.

1. Log in to the vSphere Client by using the credentials of the administrator account.
2. Click the main navigation menu
   ( ),
   and select **Administration**.
3. Under Deployment, click **Customer Experience Improvement Program**.
4. Click **Join** to join the CEIP or **Leave Program** to leave the Program.

Organizing Your vSphere Inventory

Plan how to set up your virtual inventory and consider how the virtual machines that it will support are going to be used and administered.

A large vSphere implementation might contain several virtual data centers with a complex arrangement of hosts, clusters, resource pools, and networks. It might involve multiple vCenter systems connected using vCenter linking. Smaller implementations might require a single virtual data center with a much less complex topology.

Here are the questions to answer as you create and organize an inventory of virtual objects:

- Will some virtual machines require dedicated resources?
- Will some virtual machines experience periodic spikes in workload?
- Will some virtual machines need to be administered as a group?
- Will some virtual objects require one set of system permissions, while other objects will require a different set of permissions?
- Do you want to use multiple vSphere Standard Switches, or you want to have a single vSphere Distributed Switch per data center?
- Do you want to use vMotion and Distributed Resource Management with certain virtual machines but not others?

The left pane of the vSphere Client displays your vSphere inventory. You can add and arrange objects in any way with the following considerations:

- The name of an inventory object must be unique with its parent.
- vApp names must be unique within the Virtual Machines and Templates view.
- System permissions are inherited and cascade. When you assign a system permission to an object in the inventory, the same permission propagates down the object hierarchy.

Tasks for Organizing Your Inventory

Populating and organizing your inventory involves the following activities:

> **Note:**
> vCenter supports an 80 character limit for all its entities. When you create a new inventory object, if the name exceeds this limit, the task fails and a warning appears.

- Creating data centers.
- Adding hosts to the data centers.
- Organizing inventory objects in folders.
- Setting up networking by using vSphere Standard Switches or vSphere Distributed Switches. To use services such as vMotion, TCP/IP storage, VMware vSAN™, and Fault Tolerance, setup VMkernel networking for these services. For more information, see *vSphere Networking*.
- Configuring storage systems and creating datastore inventory objects to provide logical containers for storage devices in your inventory. See *vSphere Storage*.
- Creating clusters to consolidate the resources of multiple hosts and virtual machines. You can enable vSphere HA and vSphere DRS for increased availability and more flexible resource management. See *vSphere Availability* for information about configuring vSphere HA, and *vSphere Resource Management* for information about configuring vSphere DRS.

- Creating resource pools to provide logical abstraction and flexible management of the resources in vSphere. Resource pools can be grouped into hierarchies and used to hierarchically partition available CPU and memory resources. See *vSphere Resource Management* for details.

How Do You Create a vSphere Data Center

A virtual data center is a container for all the inventory objects required to complete a fully functional environment for operating virtual machines. You can create multiple data centers to organize groups of environments to meet different user needs.

Required privileges:

- **Datacenter** > **Create datacenter**

For example, you can create a data center for each organizational unit in your enterprise or create some data centers for high-performance environments and other data centers for less demanding environments.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Inventory**.
2. Select **Hosts and Clusters**.
3. Right-click the vCenter object and select **New Datacenter**.
4. Optional: Enter a name for the data center and click **OK**.

Add hosts, clusters, resource pools, vApps, networking, datastores, and virtual machines to the data center.

How to Create a Folder in Your vSphere Inventory

In the vSphere Client,you can create folders and use them to group objects of the same type for easier management. For example, you can apply a common set of permissions to the folder and these permissions apply to all objects grouped in the folder.

A folder can contain other folders, or a group of objects of the same type. For example, one folder can contain both virtual machines and another folder that contains virtual machines, but it cannot contain both hosts and a folder that contains virtual machines.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select either a data center or another folder as a parent object for the folder that you want to create.
4. Right-click the parent object and click **New Folder**.
   - If the parent object is a folder, the new folder is of the same type as the parent folder - it can contain only objects of the same type that the parent folder contains.
   - If the parent object is a data center, you can create one of four types of folders: **Host and Cluster** folders, **Network** folders, **Storage** folders, and **VM and Template** folders.
5. Enter a name for the folder and click **OK**.

Move objects into the folder by right-clicking the object and selecting **Move To**. Select the folder as the destination. You can also move an object by dragging it to the destination folder.

How to Add a Host to Your vSphere Data Center or Folder

In the vSphere Client, you can add hosts under a data center object, a folder object, or a cluster object. If a host contains virtual machines, those virtual machines are also added to the inventory.

- Verify that a data center or a folder exists in the inventory.
- Obtain the user name and password of the root user account for the host.
- Verify that hosts behind a firewall are able to communicate with the vCenter system and all other hosts through port 902 or another custom-configured port.
- Verify that all NFS mounts on the host are active.
- Verify that you have the proper privileges. Different sets of privileges apply when you add multiple hosts to a cluster and a single host to a cluster or a data center. For more information, see Required vCenter Privileges for Common Tasks.
- If you want to add a host with more than 512 LUNs and 2,048 paths to the vCenter inventory, verify that the vCenter instance is suitable for a large or an x-large environment.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Navigate to a data center or folder within a data center.
4. Right-click the data center or folder and select **Add Host**.
5. On the **Name and location** page, enter the IP address or the name of the host and click **Next**.
6. On the **Connection settings** page, enter administrator credentials and click **Next**.
7. On the **Host summary** page, review the summary of the host details and click **Next**.
8. On the **Host lifecycle** page, the check box **Manage host with an image** check is selected by default.
   - If you want to manage the host with an image, leave the check box selected and click **Next**.

     For more information about using an image to manage the lifecycle of a standalone ESX host that is part of your vCenter inventory, see Managing the Lifecycle of Standalone ESX Hosts with vSphere Lifecycle Manager Images at Host Level in the *Managing Host and Cluster Lifecycle* documentation.
   - If you do not want to manage the host with an image, deselect the check box and click **Next**.
9. If you manage the host with an image, on the **Image** page, set up the desired image and click **Next**.
   a) Select an ESX version.
   b) Optional: Select a vendor add-on and the version of the add-on.
10. On the **Assign license** page, add a license to the host.
11. Optional: Select a lockdown mode option to deactivate the remote access for the administrator account after vCenter takes control of this host and click **Next**.
12. Optional: On the **VM location** page, select a location for the virtual machines that reside on the host and click **Next**.
13. Review the summary and click **Finish**.

A new task for adding the host appears in the Recent Tasks pane. It might take a few minutes for the task to complete.

How Do You Create and Configure Clusters in the vSphere Client

You can create clusters in the vSphere Client and then configure them manually or by using the Quickstart workflow.

A cluster is a group of hosts. When a host is added to a cluster, the resources of the host become part of the resources of the cluster. The cluster manages the resources of all hosts that it contains.

When you create clusters, you can enable vSphere High Availability (HA), vSphere Distributed Resource Scheduler (DRS), and the VMware vSAN features.

You can create a cluster that you manage with a single image. By using vSphere Lifecycle Manager images, you can easily update and upgrade the software and firmware on the hosts in the cluster. During cluster creation, you can select a reference host and use the image on that host as the image for the newly created cluster. For more information about using images to manage ESX hosts and clusters, see How to Use vSphere Lifecycle Manager Images in the *Managing Host and Cluster Lifecycle* documentation.

How Do You Create a vSphere Cluster with the vSphere Client

You can create a new vSphere cluster object by using the vSphere Client.

- Verify that a data center, or a folder within a data center, exists in the inventory.
- Verify that hosts have the same ESX version and patch level.
- Obtain the user name and password of the root user account for the host.
- If you want to extend a cluster with initially configured networking, verify that hosts do not have a manual vSAN configuration or a manual networking configuration.
- To create a cluster that you manage with a single image, review the requirements and limitations information in the*Managing Host and Cluster Lifecycle* documentation.

Required privileges:

- **Host** > **Inventory** > **Create cluster**

The clusters that you create can use vSphere Lifecycle Manager images for host updates and upgrades.

A vSphere Lifecycle Manager image is a combination of vSphere software, driver software, and desired firmware with regard to the underlying host hardware. The image that a cluster uses defines the full software set that you want to run on all ESX hosts in the cluster: the ESX version, additional VMware-provided software, and vendor software, such as firmware and drivers.

The image that you define during cluster creation is not immediately applied to the hosts. If you do not set up an image for the cluster, the cluster uses baselines and baseline groups. During cluster creation, you can select a reference host and use the image on that host as the image for the newly created cluster. For more information about using images and baselines to manage hosts in clusters, see the *Managing Host and Cluster Lifecycle* documentation.

1. In the vSphere Client, click the main navigation menu
   (**),**
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a data center.
4. Right-click the data center and select **New Cluster**.
5. Enter a name for the cluster.
6. Select DRS, vSphere HA, or vSAN cluster features.

Option	Description
To use DRS with this cluster	1. Slide the switch to the right to enable the DRS service. 2. Click the info icon on the left to see the **Default Settings** for the DRS service. The default values are: – Automation Level: Fully Automated Migration – Threshold: 3
To use vSphere HA with this cluster	1. Slide the switch to the right to enable the vSphere HA service.

Option	Description
	2. Click the info icon on the left to see the **Default Settings** for the vSphere HA service. You are present with the following default values: Host Monitoring: Enabled Admission Control: Enabled VM Monitoring: Disabled
To use vSAN with this cluster	• Slide the switch to the right to enable the vSAN service. For more information on vSAN, see Preparing a New or Existing Cluster for vSAN in the *Planning and Configuring vSAN* chapter in the *VMware Cloud Foundation* documentation.

7. Select how to set up an image for the cluster. Click the info icon to the right of each option for more information.
8. Optional: If you want to manage the configuration at cluster level by using vSphere Configuration Profiles, select the check box **Manage configuration at a cluster level**. For more information about vSphere Configuration Profiles, see What is vSphere Configuration Profiles.
9. Click **Next**.
10. Select an image to assign to the cluster, and click **Next**.
11. Review the cluster details and click **Finish**.

    The cluster appears in the vCenter inventory. The **Quickstart** workflow appears under **Configure** > **Configuration**.

You can see the empty cluster in the vCenter inventory.

You can use the Quickstart workflow to easily configure and expand the cluster. You can also skip the Quickstart workflow and continue configuring the cluster and its hosts manually.

How to Extend and Configure Your vSphere Cluster by Using the Quickstart Workflow

You can extend and configure a cluster by using the simplified Quickstart workflow in the vSphere Client. Quickstart groups common tasks and offers configuration wizards that guide you through the process of configuring and extending a cluster.

After you provide the required information on each wizard, your cluster is configured based on your input. When you add hosts using the Quickstart workflow, hosts are automatically configured to match the cluster configuration.

After the cluster creation operation completes, you are redirected to the **Cluster quickstart** page located under **Configure** > **Configuration**. The Quickstart workflow consists of three cards for quickly extending and configuring your clusters.

Table 93: Quickstart workflow cards for extending and configuring a cluster

Cluster Quickstart Workflow Card	Description
Cluster basics	You can edit the cluster name, and activate or deactivate cluster services. The card lists the services that you enabled.
Add hosts	You can add new ESX hosts. After the hosts are added, the card shows the total number of hosts present in the cluster and displays health check validation for those hosts.
Configure cluster	You can configure network settings for vMotion and vSAN traffic, review and customize cluster services, and set up a vSAN datastore. After the cluster is configured, the card provides details on configuration mismatch and reports cluster health results through the vSAN Health service.

Characteristics of a Cluster Configured Using the Quickstart Workflows

A vSphere cluster that is configured using the Quickstart workflow has the following characteristics.

- Hosts are of version ESX 7.0 and later.

- Hosts end up having similar configuration, including network settings.
- Cluster configuration is based on the recommended default settings for networking and different services.
- Licenses cannot be assigned using the Quickstart workflow. You must manually assign the required licenses. See the VCF Licensing documentation.

Skipping Quickstart

The **Skip Quickstart** button prompts you to continue configuring the cluster and its hosts manually. To confirm exiting the simplified configuration workflow, click **Continue**. After you dismiss the **Cluster quickstart** workflow, you cannot restore it for the current cluster.

How to Add an ESX Host to Your vSphere Cluster by Using the Quickstart Workflow

You can add new and existing ESX hosts to a cluster in the vCenter inventory.

- Verify that hosts have the same ESX version and patch level.
- Obtain the user name and password of the root user account for the host.
- If you want to extend a cluster with initially configured networking, verify that hosts do not have a manual vSAN configuration or a manual networking configuration.
- Verify that you have the proper privileges. Different sets of privileges apply when you add multiple hosts to a cluster and a single host to a cluster or a data center.
- To add a host to a cluster that you manage with a single image, see Add Hosts to a Cluster that Uses an Image.

You can also add hosts to a DRS cluster. For more information, see the *vSphere Resource Management* documentation.

> **Note:**
> After you configure the cluster by using Quickstart, if you modify any cluster networking settings outside of Quickstart, you cannot use the Quickstart workflow to add and configure new hosts to the cluster.

1. In the vSphere Client, click the main navigation menu
   (**),**
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Navigate to a cluster within a data center.
4. On the **Configure** tab, select **Configuration** > **Quickstart**.
5. Click **Add** in the **Add hosts** card.
6. On the **Add hosts** wizard, add new or existing hosts to the cluster.
   - Add hosts that are not part of the vCenter inventory.
     a. Click the **New hosts** tab.
     b. Populate the IP Address and credentials text boxes for those hosts.
     c. To add more new hosts, click the **Add Host** button.
     d. To reuse the credentials for all added hosts, select the **Use the same credentials for all hosts** check box.
   - Add hosts that are managed by your vCenter instance and are in the same data center as your cluster. The hosts must not be part of another cluster on the vCenter instance.
     a. Click the **Existing hosts** tab.
     b. From the list, select the hosts that you want to add to the cluster.
7. Click **Next**.

   The **Host summary** page lists all hosts that will be added to the cluster and related warnings.

Note:

If a host cannot be validated automatically by the system, you are prompted to manually validate its certificate and accept its thumbprint in the **Security Alert** pop-up.

8. On the **Host summary** page, review the details of the added hosts and click **Next**.
9. On the **Import Image** page, select the host whose image to use as the image for the cluster.

   The **Import Image** page appears when you add hosts to a cluster managed with a single image. For information about adding a host to a cluster that you manage with a single image, see Add Hosts to a Cluster that Uses an Image in the *Managing Host and Cluster Lifecycle* documentation.
10. On the **Review** page, review the IP addresses or FQDN of the added hosts and click **Finish**.

    Review the number of added hosts and the health check validation, performed by the vSAN Health service, in the **Add hosts**card.
11. Optional: Click **Re-validate** to trigger the validation of the hosts.

Note:

If an error occurs, it is visible in the **Recent Tasks** pane only.

All hosts are placed in maintenance mode and added to your cluster. You can manually exit the maintenance mode.

Configure your cluster default settings through the Quickstart workflow.

How to Configure Your vSphere Cluster by Using the Quickstart Workflow

Learn how to use the Quickstart workflow to quickly configure the settings of a vSphere cluster.

To configure the host networking settings on your host and to customize the cluster settings, start the **Configure cluster** wizard, part of the cluster Quickstart workflow. Learn how to use Quickstart to configure a vSAN cluster, see *Using Quickstart to Configure and Expand a vSAN Cluster* in the *vSAN Planning and Deployment* documentation.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a cluster.
4. On the **Configure** tab, select **Configuration** > **Quickstart**.

   The **Cluster Quickstart** page appears.

   Note:

   To configure your cluster host networking and services manually by referring to different parts of the vSphere software, click the **Skip quickstart** button. If you dismiss the **Cluster quickstart** workflow, you cannot restore it, and you have to configure manually any hosts that you add to this cluster in the future.
5. In the **Configure cluster** card, select **Configure**.

   The **Configure cluster** wizard appears.
6. On the **Distributed switches** page, configure the cluster networking.

   Alternatively, you can select the Configure networking settings later check box to hide all options that are related to cluster networking and to change the recommended host networking manually at a later time.

CAUTION:

After you select the Configure networking settings later check box, and complete the **Configure cluster** workflow, you cannot perform the cluster networking configuration in the future by using the **Configure cluster** wizard.

a) In the **Distributed switches** section, specify the number of distributed switches to create from the drop-down menu.

Note:
You can select up to three distributed switches.

The selected distributed switches are configured as part of this workflow and all hosts in the cluster connect to them.

b) Enter a unique name for each of the distributed switches you are about to create.

c) Optional: Click **Use Existing** to select an existing compatible distributed switch and an existing compatible distributed port group.

d) In the **Port groups** section, set up the vMotion network by selecting a distributed switch from the drop-down menu and assigning a new default port group to it.

e) In the **Physical adapters** section, for each physical network adapter (NIC), select the distributed switch name from the drop-down menu.

The new distributed switch must be assigned to at least one physical adapter.

Note:
If you are using an existing distributed switch, the physical adapter selection must match the current mapping of the distributed switch. Any variation results in an error.

This mapping of physical NICs to the distributed switches is applied to all hosts in this cluster.

f) Click **Next**.

7. If the vSphere DRS feature is enabled on the cluster, configure the networking options in the **vMotion traffic** page.

a) Optional: Select the **Use VLAN** check box and enter an ID for the vMotion distributed port group.

b) Optional: Select a protocol type from the drop-down menu.

c) Select an IP configuration type from the drop-down menu.

d) Optional: Populate the text boxes for each host in the cluster depending on the IP address type you need for setting up the networking.

If the IP address type is set to `DHCP`, DHCP is used to obtain the IP settings for the vMotion traffic.

e) Click **Next**.

The **Advanced options** page appears.

8. On the **Advanced options** page, customize the cluster settings depending on the services you enabled.

a) If you enabled the vSphere HA feature during cluster creation, use the options in the **vSphere HA** section to activate or deactivate host failure monitoring, virtual machine monitoring, and admission control.

If you enable admission control, you can specify the failover capacity by number of hosts.

b) If you enabled the vSphere DRS feature during cluster creation, the **Distributed Resource Scheduler** section is visible.

1. Set the Automation level to Fully Automated, Partially Automated or Manual.
2. Select one of the five migration settings from the Migration threshold drop-down menu.

c)

1. Select a lockdown mode from the drop-down menu.
2. Enter an NTP server address or FQDN.
   If you enter more than one NTP server addresses, separate them by using commas.
3. Select a host update option from the drop-down menu.

The settings are applied across all hosts in this cluster.

d) In the **Enhanced vMotion Compatibility** section, enable Enhanced vMotion™ Compatibility (EVC) and select the CPU model from the EVC mode drop-down menu.
e) Click **Next**.

The **Review** page appears.

9. Review the settings and select **Finish**.
The card closes, and the progress of the operation appears in the **Recent Tasks** pane.

You have created a fully configured cluster in the vCenter inventory.

Expand your cluster manually or by using the Quickstart workflow and the **Add hosts** card.

How to Extend Your vSphere Cluster with Host Networking Configuration

By using the Quickstart Workflow, you can extend a hyper-converged cluster by adding hosts and configuring their networking to match the cluster configuration.

- Verify that you have an existing cluster and hosts added to it.
- In the initial cluster configuration, you configured the host networking.
- Verify that hosts have the same ESX version and patch level.
- Obtain the user name and password of the root user account for the host.
- If you want to extend a cluster with initially configured networking, verify that hosts do not have a manual vSAN configuration or a manual networking configuration.
- To add a host to a cluster that you manage with a single image, see Add Hosts to a Cluster that Uses an Image in the *Managing Host and Cluster Lifecycle* documentation.

Note:
If you modify any cluster networking settings outside of Quickstart, you cannot use the Quickstart workflow to add and configure new hosts to the cluster.

1. In the vSphere Client, click the main navigation menu
( ), and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and select a configured cluster.
3. On the **Add hosts** page, add new or existing hosts to the cluster.
   - Add hosts that are not part of the vCenter inventory.
     a. Click the **New hosts** tab.
     b. Populate the IP Address and credentials text boxes for those hosts.
     c. To add more new hosts, click the **Add Host** button.
     d. To reuse the credentials for all added hosts, select the **Use the same credentials for all hosts** check box.
   - Add hosts that are managed by your vCenter instance and are in the same data center as your cluster.
     a. Click the **Existing hosts** tab.
     b. From the list, select the hosts that you want to add to the cluster.
4. Click **Next**.
The **Host summary** page lists all hosts that will be added to the cluster and related warnings.

Note:
If a host cannot be validated automatically by the system, you are prompted to manually validate its certificate and accept its thumbprint in the **Security Alert** pop-up.

5. On the **Host summary** page, review the details of the added hosts and click **Next**.
6. Optional: On the **Import Image** page, select the host whose image to use as the image for the cluster.

   The **Import Image** page appears when you add hosts to a cluster managed with a single image. For information about adding a host to a cluster that you manage with a single image, see Add Hosts to a Cluster that Uses an Image in the *Managing Host and Cluster Lifecycle* documentation.
7. On the **Ready to complete** page, review the IP addresses or FQDN of the added hosts and click **Finish**.

   The **Extend Cluster Guide** page appears.
8. In the **Configure cluster** card, select **Configure**.

   The **Configure cluster** wizard appears.
9. If the vSphere DRS feature is enabled on the cluster, configure the networking options in the **vMotion traffic** page.
   a) Optional: Select the **Use VLAN** check box and enter an ID for the vMotion distributed port group.
   b) Optional: Select a protocol type from the drop-down menu.
   c) Select an IP type from the drop-down menu.
   d) Optional: Populate the text boxes for each host in the cluster depending on the IP address type you need for setting up the networking.

      If the IP address type is set to `DHCP`, DHCP is used to obtain the IP settings for the vMotion traffic.
10. Click **Next**.

    The **Review** page appears.
11. Review the settings and select **Finish**.

    The card closes, and the progress of the operation appears in the **Recent Tasks** pane.

After successful validation, your newly added hosts are configured as the existing hosts in your cluster and the **Configure** button in the **Configure hosts** card becomes inactive. You can only click **Re-validate** to verify the cluster configuration.

Add more hosts to the cluster.

How to Extend and Configure Your vSphere Cluster Manually

You can extend a cluster by manually adding hosts to that cluster. If you previously configured the cluster without setting up the host networking, the configuration of the existing hosts in the cluster is applied to the newly added hosts.

- Verify that you have an existing cluster and hosts added to it.
- Verify that hosts have the same ESX version and patch level.
- Obtain the user name and password of the root user account for the host.
- During the initial cluster configuration, select the Configure networking settings later check box. For more information, see How to Configure Your vSphere Cluster by Using the Quickstart Workflow.
- To add a host to a cluster that you manage with a single image, see Add Hosts to a Cluster that Uses an Image in the *Managing Host and Cluster Lifecycle* documentation.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and select a configured cluster.
3. On the **Add hosts** page, add new or existing hosts to the cluster.
   - Add hosts that are not part of the vCenter inventory.
     a. Click the **New hosts** tab.
     b. Populate the IP Address and credentials text boxes for those hosts.
     c. To add more new hosts, click the **Add Host** button.

d. To reuse the credentials for all added hosts, select the **Use the same credentials for all hosts** check box.

- Add hosts that are managed by your vCenter instance and are in the same data center as your cluster. The hosts must not be part of another cluster on the vCenter instance.

  a. Click the **Existing hosts** tab.
  b. From the list, select the hosts that you want to add to the cluster.

4. Click **Next**.

   The **Host summary** page lists all hosts that will be added to the cluster and related warnings.

   Note:

   If a host cannot be validated automatically by the system, you are prompted to manually validate its certificate and accept its thumbprint in the **Security Alert** pop-up.

5. On the **Host summary** page, review the details of the added hosts and click **Next**.
6. Optional: On the **Import Image** page, select the host from which an image must be imported to the cluster.

   The **Import Image** page appears when you add hosts to a cluster managed with a single image. For information about adding a host to a cluster managed with a single image, see Add Hosts to a Cluster that Uses an Image in the *Managing Host and Cluster Lifecycle* documentation.

7. On the **Review** page, click **Finish**.

   The **Cluster Quickstart** page appears.

8. Click **Skip Quickstart** to continue configuring the cluster manually.

   CAUTION:

   After you dismiss the Quickstart workflow, you cannot enable it again on the cluster.

   Note:
   You must manually configure all hosts added to the cluster after dismissing the Quickstart workflow.

Manually configure all cluster settings and add more hosts to the cluster.

vSphere Tags and Custom Attributes

Tags and attributes allow you to attach metadata to objects in the vSphere inventory to make it easier to sort and search for these objects.

What Are vSphere Tags and How to Use Them

You can create, edit, and delete tag categories and vSphere tags. You can also assign vSphere tags to objects in the vCenter inventory and manage the user privileges for working with tags and categories.

A tag is a label that you can apply to objects in the vSphere inventory. When you create a tag, you assign that tag to a category. Categories allow you to group related tags together. When you define a category, you can specify the object types for its tags, and whether more than one tag in the category can be applied to an object.

For example, if you wanted to tag your virtual machines by guest operating system type, you can create a category called operating system. You can specify that it applies to virtual machines only and that only a single tag can be applied to a virtual machine at any time. The tags in this category might be Windows, Linux, and Mac OS.

Tags and categories can span multiple vCenter instances:

- If multiple vCenter instances are configured to use vCenter linking, tags and tag categories are replicated across all these vCenter instances.
- To manage tags at scale, across vCenter instances managed by the same VCF Operations instance, you can also use the tag management capabilities in VCF Operations. For more information, see Tags and Categories Overview.

Tags can also be used when you configure compute or storage policies. For example, if you have critical workloads that need to be run on hosts with high network performance, you can create a specific tag and assign the tag to the virtual

machines with the respective workloads. You can configure a compute policy and specify that virtual machines with that specific tag must be placed in a host that has network performance.

How Do You Create and Edit a vSphere Tag Category

You use categories in your vSphere environment to group tags together and define how tags can be applied to objects. You create and edit a tag category from the vSphere Client.

The required privilege depends on the task that you want to perform.

Task	Privilege
Create a tag category	**vSphere Tagging** > **Create vSphere Tag Category**
Edit a tag category	**vSphere Tagging** > **Edit vSphere Tag Category**

You can create a tag category explicitly, as explained here, or as part of the tag creation process. Each tag has to belong to at least one tag category.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Tags & Custom Attributes**.
2. Click the **Tags** tab and click **Categories**
3. Start the task that you want to perform.

Task	Steps to perform
Create a tag category	Click **New**.
Edit a tag category	Select a category and click **Edit**.

4. Edit the category settings.

Setting	Description
Category Name	The category name must be unique to the currently selected vCenter system. Enter a category name that describes common characteristics, for example license requirements, or virtual machines that you plan to tag and include in the category.
Description	You can provide text in the description to describe the purpose or use of the category.
Tags Per Object	• If you select **One Tag**, you can apply only one tag from this category to an object. Use this option for categories whose tags are mutually exclusive. For example, if you have a category called Priority with tags High, Medium, and Low, then each object should have only one tag because an object can have only one priority. • If you select **Many tags**, you can apply more than one tag from the category to an object. Use this option for categories whose tags are not mutually exclusive. After you have set Tags Per Object, you can change from **One Tag** to **Many Tags**, but not from **Many Tags** to **One Tag**.
Associable Object Types	Select whether tags in this category can be assigned to all objects or only to a specific type of object, such as a virtual machine or a datastore. Changes to the associable object type are limited. • If you initially selected a single object type, you can later change the category to work for all object types.

Setting	Description
	• If you initially selected All Objects, you cannot restrict the category later.

5. Click **Create** or **Save**.

How Do You Delete a vSphere Tag Category

Learn how to remove a vSphere tag category from your vSphere environment.

Required privilege: InventoryService.Tagging.DeleteCategory.

Deleting a category also deletes all tags associated with the category.

1. In the vSphere Client, click the main navigation menu

   and select **Tags & Custom Attributes**.
2. Click the **Tags** tab, and click **Categories**.
3. Select a category from the list and click **Delete**.
   The **Delete Category** dialog opens.
4. To confirm the operation, click **Delete**.

The category and all associated tags are deleted.

How Do You Create and Edit a vSphere Tag

Read how to create or edit a vSphere tag. After you create a tag, you can use it to add metadata to inventory objects.

The required privilege depends on the task that you want to perform.

Task	Privilege
Create a tag	**vSphere Tagging** > **Create vSphere Tag** on any vCenter inventory object.
Edit a tag	**vSphere Tagging** > **Edit vSphere Tag** on any vCenter inventory object.

You can use tags to add metadata to inventory objects. You can also record information about your inventory objects in tags, and you can use the tags in searches. For information about creating and editing a tag category, see How Do You Create and Edit a vSphere Tag Category.

1. In the vSphere Client, click the main navigation menu

   and select **Tags & Custom Attributes**.
2. Select the **Tags** tab, and click **Tags**.
3. Start the task that you want to perform.

Task	Steps to perform
Create a tag	Click **New**.
Edit a tag	Select a tag and click **Edit**.

4. In the dialog box, enter or edit the name for the tag.
   You can use up to 256 characters for the tag name.

5. Enter or edit the description of the tag.
6. If you create a tag, specify the tag category.
   - Select an existing category from the **Category** drop-down menu.
   - Click **Create New Category** and select the newly created category.
7. Click **Create** or **Save**.

How Do You Delete a vSphere Tag

You can delete an existing vSphere tag when you no longer need it by using the vSphere Client.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Tags & Custom Attributes**.
2. Select the **Tags** tab and click **Tags**.
3. Select one or more tags from the list and click **Delete**.
4. To confirm the operation, click **Delete**.

The selected tags are deleted.

Use Advanced Filters to Filter Tags in the vSphere Client

Use the advanced filter options to create a set of filtering criteria and find specific tags and categories in your vSphere Client.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Tags & Custom Attributes**.
2. Select the **Tags** tab.
3. If you want to filter tags, click **Tags**.
4. If you want to filter categories, click **Categories**.
5. Click the drop-down menu in the left upper corner of the tags or categories table, and select **Advanced Filter**.
6. Click **Add New**.

   A pop-up window appears.
7. From the drop-down menu under Filter, select the filtering parameter.
8. From the drop-down menu under Operator, select how the filtering criteria must relate to each other.
9. Enter the filter value.
10. If you want to specify the filtering criteria further, click **Add Condition**, and enter the required details for the second filter operator.
11. Click **Apply**.

    A list of tags or categories that meet your filtering criteria is displayed in your selected sorting order. The filters that you apply are displayed on top of the inventory list.

    Note:

    You can apply multiple advanced filters to the inventory list. They are combined with the logical operator *and*.

12. Optional: Optional: To edit a filter that you applied, click the filter displayed on top of the inventory list, edit the filtering criteria, and click **Apply**.
13. Optional: Optional: To hide all filters applied to the inventory list, click **Hide All**.

    The filters continue to be applied.

To delete a filter that you applied, click the remove icon (

×

) next to the filtering criterion. If the filter consists of more than one filtering criteria, you should remove each one separately.

To delete all filters applied to the inventory list, click **Clear All**.

How Do You Assign or Remove a vSphere Tag

After you create vSphere tags, you can apply or remove them as metadata to objects in the vCenter inventory.

Required privilege: InventoryService.Tagging.AttachTag.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Navigate to an inventory tree.
3. Select an object from the list and click **Actions**.
4. From the drop-down menu, select **Tags and Custom Attributes**.
5. Select the required action.
   - To assign a tag, select **Assign Tag**.
   - To remove a tag, select **Remove tag**.
6. Select a tag from the list and click **Assign**.

   In the **Assign Tag** dialog box, you can also create new tags with **Add Tag**. For information about creating a tag, see How Do You Create and Edit a vSphere Tag.

How Do You Add Permissions for vSphere Tags and Tag Categories

You can manage the user privileges for working with tags and categories. The procedure for assigning permissions to tags is the same as the procedure for assigning permissions to tag categories.

When you create a tag, you can specify which users and groups can operate with that tag. For example, you can grant administrative rights only to administrators and set read-only permissions for all other users or groups. You must have vSphere administrator credentials to set and manage permissions for tags.

Permissions for tags work similar to permissions for vCenter inventory objects. For more information, see the *vSphere Security* documentation.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Tags & Custom Attributes**.
2. On the **Tags** tab, click the **Tags** or **Categories** button.

   Depending on the button that you click, you see the list of tags or the list of tag categories.

3. Select an item from the list and click **Add Permission**.
4. In the **Add Permission** dialog box, select a domain from the drop-down menu.
5. Search for a user or a group to add.
6. Select a role to add from the drop-down menu.
7. To enable permission inheritance, select the **Propagate to children** check box.
8. Click **OK**.

vSphere Tagging Best Practices

Incorrect tagging can lead to replication errors. To avoid these errors, diligently follow best practices when tagging objects in your vSphere environment.

When working with tags in multiple node situations, expect replication delays between the nodes (generally 30 seconds to 2 minutes depending on your setup).

Follow these best practices to avoid replication errors:

- After creating a tag, if you immediately assign that tag to a local object, assign it from the management node where you created the tag.
- After creating a tag, if you immediately assign that tag to a remote object, assign it from the management node to which the object is local. Depending on your environment setup, allow for replication time to propagate the new tag before you use the tag.
- Avoid simultaneously creating categories and tags from different management nodes before categories and tags across nodes can finish the replication process. If duplicate categories or tags are created from different nodes at the same time, the duplicates might not be detected and will appear. If you see these results, manually delete duplicates from one management node.
- Before you remove an object from the vCenter inventory that is not a virtual machine or a host, first remove the tags from the object.

For more information about tagging performance best practices, see the blog post VMware vCenter 8.0 U3 Tagging Performance Best Practices.

What Are Custom Attributes in the vSphere Client

You can use custom attributes in the vSphere Client to assign user-specific values for each object of the custom attribute type.

After you create the attributes, set the value for the attribute on each virtual machine or managed host, as appropriate. This value is stored with vCenter and not with the virtual machine or managed host. Use the new attribute to filter information about your virtual machines and managed hosts. If you no longer need the custom attribute, remove it. A custom attribute is always a string.

For example, suppose that you have a set of products and you want to sort them by sales representative. Create a custom attribute for the sales person's name, Name. Add the custom attribute, Name, column to one of the list views. Add the appropriate name to each product entry. Click the column title Name to sort alphabetically.

The custom attributes feature is available only when you are connected to a vCenter system.

How Do You Add and Edit Custom Attributes in the vSphere Client

You can create custom attributes in the vSphere Client and associate these custom keys with an object, such as a host, virtual machine, cluster, or network. You can then assign a user-specific value using the custom attributes to specific objects in your vCenter environment.

Required privileges: Global.ManageCustomFields

After you create the attributes, set an appropriate value for the attribute on each inventory object. The attribute value is stored with vCenter and not with the inventory object. Use the new attribute to filter your inventory objects. If you no longer need the custom attribute, remove it. A custom attribute is always a string.

For example, suppose that you have lots of virtual machines in your inventory and you want to sort them by owner.

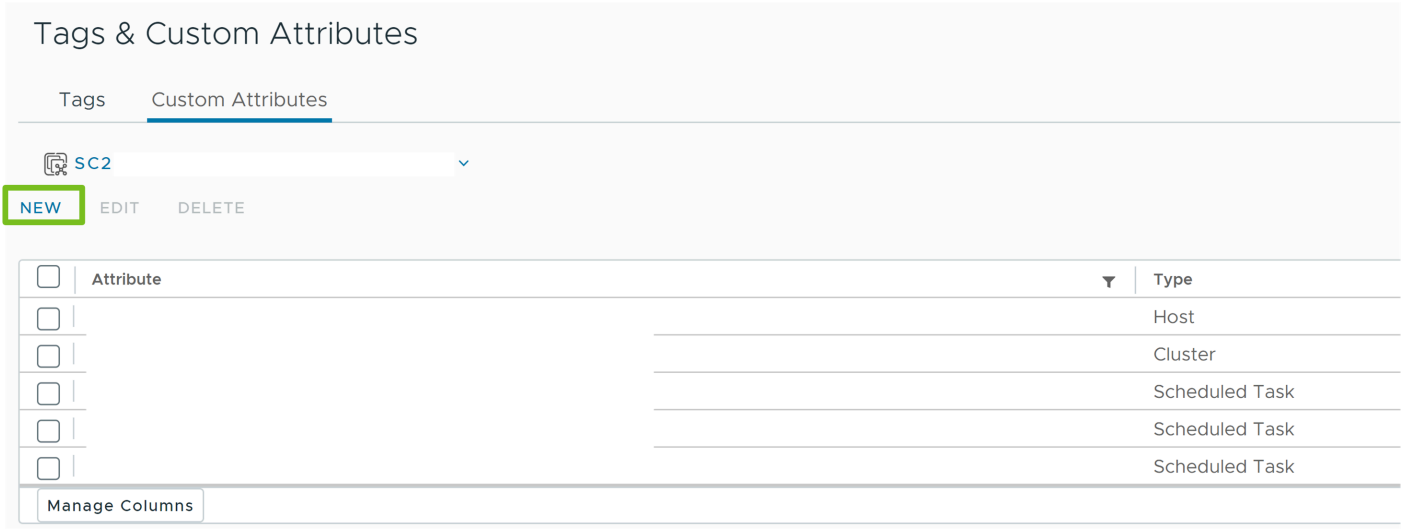
1. Create a `VM-owner` custom attribute for the virtual machine type of inventory objects.
2. Add the name of the owner to each VM entry you want and use the **Global Inventory Lists** pane to add the `VM-owner` custom attribute column to one of the list views.
3. You can now click the **VM-owner** column to sort alphabetically by owner.

   Tip:
   If you cannot use the custom attribute column to sort the list of inventory objects, you can export the content of the list view and then use the sorting options on the saved CSV file.

   Note:
   Tags and tag categories support a finer-grained mechanism for tagging your object. Consider using tags and tag categories instead of custom attributes.

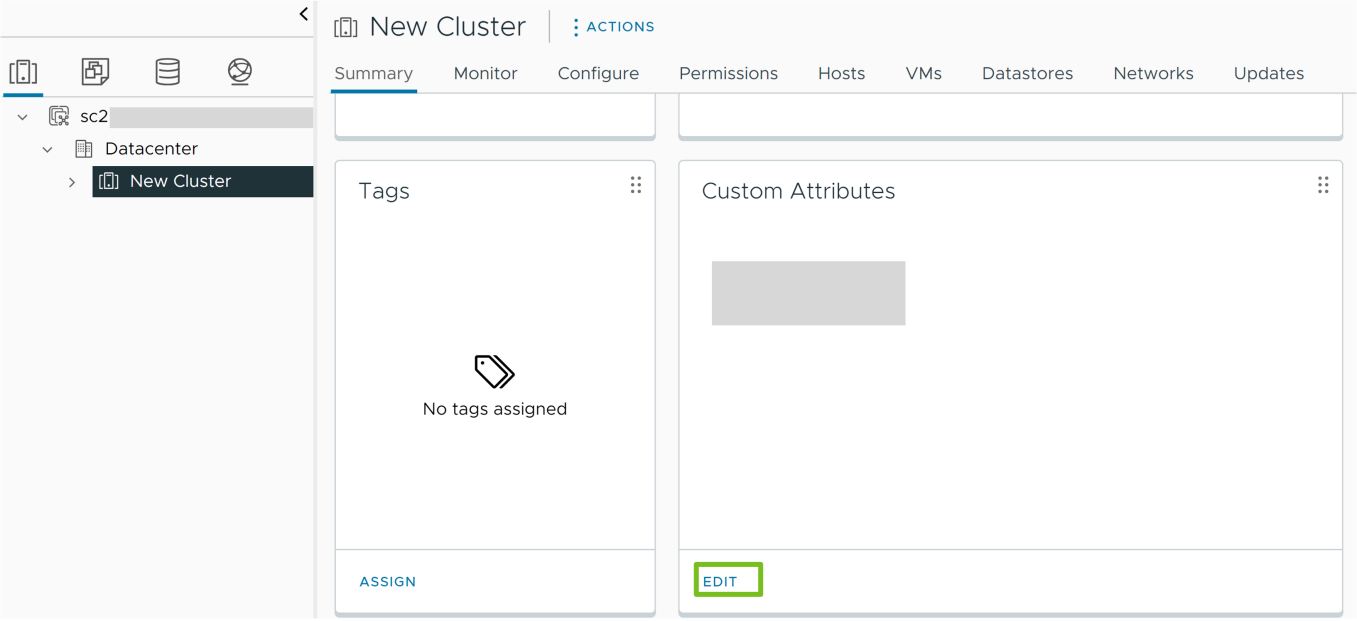
1. In the vSphere Client, click the main navigation menu ( ), and select **Tags & Custom Attributes**.
2. Select the **Custom Attributes** tab.

   All currently defined custom attributes for vCenter are displayed.
3. Click **New**.



4. Enter the values for the custom attribute.
   a) Enter the name of the attributes in the **Attribute** text box.
   b) Select the attribute type from the **Type** drop-down menu.
   c) Click **OK**.

   After you have defined an attribute on an object, it is available to all objects of that type in the inventory. However, the value you specify is applied only to the currently selected object.
5. You can later add a value to the custom attribute for each inventory object that you want.
   a) Navigate to an inventory object in your vCenter inventory.
   b) On the **Summary** tab, navigate to the **Custom Attributes** card.
   c) Click **Edit**.



- If you want to add a value to an existing custom attribute, enter or edit the attribute value in the Value column.
- If you want to create a new custom attribute, enter a name and value to the attribute and select the attribute type from the **Type** drop-down menu. Click **Add**.

d) Click **Save**.

vSphere Compute Policies

You can create policies that govern the placement of workload virtual machines in your vSphere inventory.

Creating and Managing Compute Policies

By using compute policies, you can specify how the vSphere Distributed Resource Scheduler (DRS) places virtual machines on hosts in a vSphere cluster. For more information about DRS, see Create a vSphere DRS Cluster.

Compute policies establish persistent placement constraints that are enforced not only at initial VM placement, but throughout the VM lifecycle — including during DRS load balancing, maintenance mode evacuation, and HA failover operations.

You can create, edit, or delete a compute policy. Policy conflicts are not detected when you create a policy. Policies in the system might be in conflict with each other. For example, a group of virtual machines can be part of both a VM-VM affinity policy and a VM-VM anti-affinity policy. In such cases, DRS might not be able to place the virtual machines in a way that complies with both policies.

Starting with vSphere 9.1.1, some policies are created automatically during VM creation in response to placement policy constraints specified in a virtual machine configuration specification. System-created policies are visible in the vSphere Client alongside user-created policies. In vSphere 9.1.1, you can identify system-created policies by the name prefix `AutoGenPolicy-` that is followed by the tag category name and a SHA-256 hash string. The system created policies have a description field that summarizes the full set of policy parameters in plain language.

For information on how to request system-created policies by using the bulk policy creation API, see VM-to-VM Affinity and Anti-Affinity Policies.

Note:

Affinity policies are not the same as the vSphere DRS affinity rules.

Compute Policies and vSphere Tags

Tags are the mechanism by which compute policies identify which virtual machines and hosts to govern. Before you create a VM-VM or VM-Host policy, you must have tag categories and tags in place, or you can allow the system to create

them automatically when you specify placement policies in a VM configuration specification. For more information about vSphere tags, see What Are vSphere Tags and How to Use Them.

Impact of Compute Policies During Host Replacement and Maintenance

If you configure a compute policy based on host tags, you must review the potential impact if a tagged host is placed in maintenance mode or fails and is replaced. Available resources are reduced for the duration of the replacement or maintenance operation. As a best practice, allocate a sufficient number of tagged hosts to support the workloads that are placed by compute policy when a tagged host is temporarily unavailable.

Compute Policy Types

Compute Policy	Description
VM-Host affinity	Places virtual machines in a specified category on hosts in a specified category. For more information, see Create a VM-Host Affinity Policy.
VM-Host anti-affinity	Keeps virtual machines in a specified category away from hosts in a specified category. For more information, see Create a VM-Host Anti-Affinity Policy.
VM-VM affinity	Places virtual machines sharing a specified tag on the same host, cluster, or zone. Your vSphere version must be 9.1.1 or later. For more information, see Create a VM-VM Affinity Policy.
VM-VM anti-affinity	Keeps virtual machines sharing a specified tag on different hosts, clusters, or zones. Your vSphere version must be 9.1.1 or later. For more information, see Create a VM-VM Anti-Affinity Policy.
Limit VM placement span plus one host for maintenance	Limits the number of hosts across which a group of VMs is spread, reserving capacity for maintenance. For more information, see Create a Limit VM Placement Span Plus One Host For Maintenance Policy.
VM evacuation by best effort restart on best host	Shuts down guest operating systems when a host enters maintenance mode and restarts VMs on the best available host. For more information, see Create a VM Evacuation by Best Effort Restart on Best Host Policy.

Monitoring Compute Policy Compliance

- Monitoring virtual machine compliance with a particular compute policy. In the vSphere Client, in the Summary page of each virtual machine, you can view the compute policies that apply to the virtual machine. You can also view the compliance status of the virtual machine with each policy.
- Monitoring overall compute policy compliance. In the vSphere Client, navigate to**Policies and Profiles** > **Compute Policies**. You can check the compliance status of the policy - the accumulated compliance status of all the virtual machines that are subject to that policy.

Create a VM-Host Affinity Policy

A VM-Host affinity policy establishes a relationship between a category of virtual machines and a category of ESX hosts.

- Verify that you have administrator privileges.
- Verify that DRS is activated.

By using compute policies, you can specify how the vSphere Distributed Resource Scheduler (DRS) places virtual machines on hosts in a resource pool. For more information about DRS, see Create a vSphere DRS Cluster.

You can use VM-Host affinity policies when virtual machines with workload-specific configurations require placement on hosts that have certain characteristics. You can also use VM-Host affinity policies when virtual machines that run certain applications must be placed on hosts that are licensed to run those applications.

To prevent a VM-Host affinity policy from blocking the upgrade of a host or cluster, VM-Host affinity policies cannot prevent some host-related and virtual machine-related operations.

- A policy cannot prevent a host from entering maintenance mode. If the host must be placed in maintenance mode, virtual machines with an affinity for the host are automatically migrated to another host in the cluster. The virtual machines are migrated back to the initial host when the maintenance completes and the host becomes available.

- A policy cannot prevent a host configured for HA from executing a failover. Virtual machines with an affinity for the failed host can be migrated to any available host in the cluster.
- A policy cannot prevent a virtual machine from powering-on. If a virtual machine subject to a VM-Host affinity policy specifies a resource reservation that no host can meet, it is powered on on any available host. When a host that can match the resource reservation becomes available, the virtual machine is migrated to it.

1. Log in to the vSphere Client.
2. Create a tag category and a tag for the virtual machines that you want to include in the VM-Host affinity policy.

   You can use existing tags and categories or create new ones. For more information about creating and using tags, see vSphere Tags and Custom Attributes.

   Enter a category name that describes common characteristics, such as license requirements, or virtual machines that you plan to tag and include in the category.
3. Create a tag category and a tag for the ESX hosts that you want to include in the VM-Host affinity policy.

   You can use existing tags and categories or create new ones.
4. Assign the tags to the virtual machines and hosts that you want to include in a VM-Host affinity policy. For more information about assigning a tag to an object, see How Do You Assign or Remove a vSphere Tag.
5. Create a VM-Host affinity policy.
   a) In the vSphere Client, click the main navigation menu
   ( ).
   b) Select **Policies and Profiles** > **Compute Policies**.
   c) Click **Add**.

      The **New Compute Policy** wizard appears.
   d) Enter a name for the policy.

      The policy name must be unique within your inventory.
   e) From the **Policy type** drop-down menu, select **VM-Host affinity**.
   f) Enter a description of the policy.
   g) From the **VM tag** and **Host Tag** drop-down menu, select a category and tag to which the policy applies.

      If only one tag is associated with a category, it is selected by default after you select the tag category.

      Note:

      In a stretched cluster, each host is automatically tagged with an **Availability zones** tag. The same tag is assigned to all hosts in an availability zone (AZ). You can use these tags to establish an affinity between a virtual machine and any host in the cluster that has a specific availability zone tag.

      Compute policy does not affect the location of virtual machine storage. Ensure that the virtual machine storage policies locate a copy of virtual machine storage in the AZ where the virtual machine is deployed. Compute policy does not affect network paths to and from the virtual machine, which might transit a different AZ than the one where the virtual machine is deployed.
   h) From the **Policy requirement** drop-down menu, select how the policy is applied.
      - To allow placement with violations if necessary, click **Preferred**.
      - To prevent powering on the virtual machine if the requirement in the policy cannot be met, select **Mandatory**.

      Note:

      Policy requirements apply only to initial virtual machine placement.

      Maintenance operations might override the policy requirements.

i) Click **Create**.

Create a VM-Host Anti-Affinity Policy

A VM-Host anti-affinity policy describes a relationship between a category of VMs and a category of hosts.

- Verify that you have administrator privileges.
- Verify that DRS is activated.

By using compute policies, you can specify how the vSphere Distributed Resource Scheduler (DRS) places virtual machines on hosts in a resource pool. For more information about DRS, see Create a vSphere DRS Cluster.

You can use a VM-Host anti-affinity policy when you want to avoid placing virtual machines that have specific host requirements such as a GPU or other devices, or capabilities such as IOPS control, on hosts that do not support those requirements.

To prevent a VM-Host affinity policy from blocking the upgrade of a host or cluster, VM-Host affinity policies cannot prevent some host-related and virtual machine-related operations.

- A policy cannot prevent a host from entering maintenance mode.
- A policy cannot prevent a host configured for HA from executing a failover. VMs with an anti-affinity for the failed host can be migrated to any available host in the cluster.
- A policy cannot prevent a VM from powering-on. If a VM subject to a VM-Host anti-affinity policy specifies a resource reservation that no host can meet, it is powered on on any available host.

1. Log in to the vSphere Client.
2. Create a tag category and a tag for the virtual machines that you want to include in the VM-Host anti-affinity policy.

   You can use existing tags and categories or create new ones. For more information about creating and using tags, see vSphere Tags and Custom Attributes.

   Enter a category name that describes common characteristics, such as license requirements, or virtual machines that you plan to tag and include in the category.
3. Create a tag category and a tag for the ESX hosts that you want to include in the VM-Host affinity policy.

   You can use existing tags and categories or create new ones.
4. Assign the tags to the virtual machines and hosts that you want to include in a VM-Host affinity policy. For more information about assigning a tag to an object, see How Do You Assign or Remove a vSphere Tag.
5. Create a VM-Host anti-affinity policy.
   a) In the vSphere Client, click the main navigation menu

      ( ).
   b) Select **Policies and Profiles** > **Compute Policies**.
   c) Click **Add**.

      The **New Compute Policy** wizard appears.
   d) Enter a name for the policy.

      The policy name must be unique within your inventory.
   e) From the **Policy type** drop-down menu, select **VM-Host anti-affinity**.
   f) Enter a description of the policy.
   g) From the **VM tag** and **Host Tag** drop-down menu, select a category and tag to which the policy applies.

      If only one tag is associated with a category, it is selected by default after you select the tag category.

      Note:

      In a stretched cluster, each host is automatically tagged with an **Availability zones** tag. The same tag is assigned to all hosts in an availability zone (AZ). You can use these tags to establish an affinity between a virtual machine and any host in the cluster that has a specific availability zone tag.

h) From the **Policy requirement** drop-down menu, select how the policy is applied.

- To allow placement with violations if necessary, click **Preferred**.
- To prevent powering on the virtual machine if the requirement in the policy cannot be met, select **Mandatory**.

Note:

Policy requirements apply only to initial virtual machine placement.

Maintenance operations might override the policy requirements.

i) Click **Create**.

Create a Limit VM Placement Span Plus One Host For Maintenance Policy

A policy of type limit VM placement span plus one host for maintenance describes a relationship between members of a category of virtual machines and a specified number of hosts.

- Verify that you have administrator privileges.
- Verify that DRS is activated.

By using compute policies, you can specify how the vSphere Distributed Resource Scheduler (DRS) places virtual machines on hosts in a resource pool. For more information about DRS, see Create a vSphere DRS Cluster.

A policy of type limit VM placement span plus one host for maintenance establishes a relationship between virtual machines in a given category and specified number of hosts. After the policy is created, DRS attempts to place the virtual machines from the category on a number of hosts that you specify. You can select from 1 through 96 hosts. When one of the hosts is entering maintenance-mode, it is not counted in the total number that you specified.

1. Log in to the vSphere Client.
2. Create a tag category and a tag for the virtual machines that you want to include in the policy.

   You can use existing tags and categories or create new ones. For more information about creating and using tags, see vSphere Tags and Custom Attributes.

   Enter a category name that describes common characteristics, such as license requirements, or virtual machines that you plan to tag and include in the category.
3. Assign the tags to the virtual machines that you want to include in a policy. For more information about assigning a tag to an object, see How Do You Assign or Remove a vSphere Tag.
4. Create a limit VM placement span plus one host for maintenance policy.
   a) In the vSphere Client, click the main navigation menu

   ( ), and select **Policies and Profiles** > **Compute Policies**.
   b) Click **Add**.

   The **New Compute Policy** wizard appears.
   c) Enter a name for the policy.

   The policy name must be unique within your inventory.
   d) From the **Policy type** drop-down menu, select **limit VM placement span plus one host for maintenance**.
   e) Enter a description of the policy.
   f) From the **VM tag** drop-down menu, select a category and tag to which the policy applies.

   If only one tag is associated with a category, it is selected by default after you select the tag category.
   g) Enter the number of hosts.
   h) Click **Create**.

Create a VM Evacuation by Best Effort Restart on Best Host Policy

When you apply a policy *VM evacuation by best effort restart on best host* to a virtual machine, when the host enters maintenance mode, the guest operating systems for the virtual machine shuts down.

- Verify that you have administrator privileges.
- Verify that DRS is activated.

If the guest operating system shut down is unavailable for a virtual machine that is subject to the *VM evacuation by best effort restart on best host* policy, or the guest operating system shut down cannot complete in time, the virtual machine powers off. When a virtual machine powers off as a result of the policy application, the virtual machine attempts to power on every few minutes and might power on a different host.

1. Log in to the vSphere Client.
2. Create a tag category and a tag for the virtual machines that you want to include in the policy.

   You can use existing tags and categories or create new ones. For more information about creating and using tags, see vSphere Tags and Custom Attributes.

   Enter a category name that describes common characteristics, such as license requirements, or virtual machines that you plan to tag and include in the category.
3. Assign the tags to the virtual machines that you want to include in the policy. For more information about assigning a tag to an object, see How Do You Assign or Remove a vSphere Tag.
4. Create a *VM evacuation by best effort restart on best host* policy.
   a) In the vSphere Client, click the main navigation menu

      (**),**

      and select **Policies and Profiles** > **Compute Policies**.
   b) Click **Add**.

      The **New Compute Policy** wizard appears.
   c) From the **Policy type** drop-down menu, select *VM evacuation by best effort restart on best host*.
   d) Enter a name for the policy.

      The policy name must be unique within your inventory.
   e) Enter a description of the policy.
   f) From the **VM tag** drop-down menu, select a category and tag to which the policy applies.

      If only one tag is associated with a category, it is selected by default after you select the tag category.
   g) Click **Create**.

Create a VM-VM Affinity Policy

Starting with vSphere 9.1.1, you can create a VM-VM affinity policy to place virtual machines that share a specified tag on the same host.

- Verify that you have administrator privileges.
- Verify that DRS is activated.
- Create a tag category and a tag for the virtual machines that you want to include in the VM-VM affinity policy. For more information about creating and using tags, see vSphere Tags and Custom Attributes.
- Assign the tags to the virtual machines that you want to include in a VM-VM affinity policy. For more information about assigning a tag to an object, see How Do You Assign or Remove a vSphere Tag.

The VM-VM affinity policy is important for workloads with colocation requirements, such as distributed application tiers that must not share a single point of failure.

VM-VM affinity is enforced by DRS continuously, at initial placement, during load balancing, maintenance mode, and HA failover operations.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Policies and Profiles** > **Compute Policies**.
2. Click **Add**.

   The **New Compute Policy** wizard appears.
3. From the **Policy type** drop-down menu, select **VM-VM affinity**.
4. Enter a name for the policy.

   The policy name must be unique within your inventory.
5. (Optional): Enter a description of the policy.
6. From the **VM tag** drop-down menu, select a category and tag to which the policy applies.

   If only one tag is associated with a category, after you select the tag category, the tag is selected by default.
7. Click **Create**.

The compute policy is available in the list of compute policies that are created in the vCenter instance.

To view details about a compute policy, click the compute policy name from the list.

To delete a compute policy, select it from the list, and click **Delete**.

Create a VM-VM Anti-Affinity Policy

Starting with vSphere 9.1.1, you can create a VM-VM anti-affinity policy to place virtual machines that share a specified tag on different hosts.

- Verify that you have administrator privileges.
- Verify that DRS is activated.
- Create a tag category and a tag for the virtual machines that you want to include in the VM-VM anti-affinity policy. For more information about creating and using tags, see vSphere Tags and Custom Attributes.
- Assign the tags to the virtual machines that you want to include in a VM-VM anti-affinity policy. For more information about assigning a tag to an object, see How Do You Assign or Remove a vSphere Tag.

The VM-VM anti-affinity policy is important for workloads with isolation requirements, such as distributed application tiers that must not share a single point of failure.

DRS enforces VM-VM anti-affinity policies continuously — not only at initial placement but also during load balancing, maintenance mode, and HA failover operations.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Policies and Profiles** > **Compute Policies**.
2. Click **Add**.

   The **New Compute Policy** wizard appears.
3. From the **Policy type** drop-down menu, select **VM-VM anti-ffinity**.
4. Enter a name for the policy.

   The policy name must be unique within your inventory.

5. (Optional): Enter a description of the policy.
6. From the **VM tag** drop-down menu, select a category and tag to which the policy applies.

   If only one tag is associated with a category, after you select the tag category, the tag is selected by default.
7. Click **Create**.

The compute policy is available in the list of compute policies that are created in the vCenter instance.

To view details about a compute policy, click the compute policy name from the list.

To delete a compute policy, select it from the list, and click **Delete**.

Working with vSphere Tasks

vSphere tasks are activities and actions that occur on an object within the vSphere inventory.

vSphere tasks represent system activities that do not complete immediately, such as migrating a virtual machine. For example, powering off a virtual machine is a task. You can perform this task manually every evening, or you can set up a scheduled task to power off the virtual machine every evening.

How Do You View vSphere Tasks

Learn how to view vSphere tasks that are associated with a single object or all objects in a vSphere environment.

By default, the task list for an object also includes tasks performed on its child objects. You can filter the task list by entering the object that you want in the **Target** column filter.

If you are logged in to a vCenter instance that is part of a vCenter linking group, the **Server** column in the task list displays the name of the vCenter system on which the task is performed.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to an object in the inventory.
3. Click the **Monitor** tab.
4. Under **Tasks and Events**, select **Tasks**.

   The task list contains tasks performed on the object and detailed information, such as target, task status, initiator, and start/completion time of the task.

   You can limit the number of tasks visible in the **Tasks** pane by selecting an option from the **Tasks per page** drop-down menu.
5. Optional: Click the filter ( ) icon on a column header and filter the task list by entering your filtering criteria.
6. Optional: Click the expand row (^) icon to view related events for a task. You can view task information about multiple tasks at the same time.
7. Optional: Click **Open in new tab** to open only the **Task Console** in a separate tab on your browser.

How Do You Cancel a vSphere Task

Canceling a vSphere task stops a running task from occurring. Canceling a scheduled task does not cancel subsequent runs. To cancel a scheduled task that has not run, reschedule it.

Required privileges:

- Manual tasks:**Tasks** > **Update Task**
- Scheduled tasks: **Scheduled task** > **Remove task**

1. In the vSphere Client, navigate to the **Recent Tasks** pane, and locate the task.
   By default, the **Recent Tasks** pane is displayed at the bottom of the vSphere Client.
2. Click the cancel button (⊗) next to the progress bar in the Status column for the task you want.
   If the cancel option is unavailable, the selected task cannot be canceled.
3. In the **Cancel Task** pop-up dialog box, click **OK**.

The vCenter system or ESX host stops the progress of the task and returns the object to its previous state. The vSphere Client displays the task with a status*The task was canceled by a user.*

Cancelled tasks and the corresponding events are retained in the vCenter database. For information about the retention of tasks and events in the vCenter database, and how to configure the database settings, see the *vSphere Monitoring and Performance* documentation.

How Do You Filter vSphere Tasks

To lower the number of vSphere tasks displayed for a single object or all objects in your environment, filter the task history in the database using several criteria, such as status, initiator, and time range.

1. In the vSphere Client, click the main navigation menu
   (**),**
   and select **Inventory**.
2. Navigate to an object in the inventory.
3. Click the **Monitor** tab.
4. Under **Tasks and Events**, select **Tasks**.
5. Click **Filter**.
   The **Filter Tasks** dialog opens.
6. Filter the tasks you want to view.
   a) Select the respective check boxes in the **Status** options list to filter the tasks by their status.
   b) From the **Type** drop-down menu, select the task type.
      - **User** - Displays the tasks initiated by all users, such as `vsphere.local` users, Active Directory domain users, and system users.
      - **System** - Displays the tasks initiated only by system users. System users are user accounts associated with an application or service.
   c) To view the tasks initiated by all users or by specific users, select the **All users** or **Specific users** radio button.
      If you select to view the tasks performed by specific users, create a list of users.
      1. Select the domain for the users from the drop-down menu.
      2. Select the users who initiated the tasks.
         a. Enter a name in the Search box.
            The system searches from the users in the selected domain.
         b. Select a user and click **Add**.
   d) From the **Select time set** drop-down menu, select the time when the task was started, completed, or queued.
   e) From the **Select time range** options, select the time range when the tasks were performed.
      - **Relative** - If you want to filter the tasks for a relative time range, specify the relative time range from the **Last** and **Range** drop-down menus.
      - **Date range** - If you want to filter the tasks for a specific time period, specify the date and time from the drop-down menus.

For example, to filter the tasks that got queued for the last 2 weeks, from the **Select time set** drop down menu, select **Queued time**, and select the **Relative** radio button. Then, from the **Last** drop-down menu, select **2** and from the **Range** drop-down menu, select **Weeks**.

7. Click **Filter**.

The **Tasks** page displays the tasks that match your criteria. If you want to clear the task filter, click **Clear all filters** in the upper-right corner.

How Do You Export vSphere Tasks

You can export the detailed information for selected vSphere tasks or all tasks listed in the **Tasks** page to a CSV file.

To export the information about specific tasks, you can filter the task list and then select only the tasks that you want. You can also export the information about all tasks listed for an object or all objects in the vSphere environment.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Navigate to an object in the inventory.
3. Click the **Monitor** tab.
4. Under **Tasks and Events**, select **Tasks**.
5. Optional: To export one or more tasks, click the check boxes in front of the respective tasks.
6. Click **Export** at the top-left corner of the **Tasks** pane.

   Note:
   By default, if you did not select any tasks, the detailed information about all displayed tasks is exported.

   a) Optional: If you selected one or more tasks but you want to export the information about all displayed tasks, click **All Rows**.
   b) Optional: If you want to export only the information for the selected tasks, click **Selected Rows**.

   The CSV file is generated and available for download.

How Do You Export vSphere Tasks with Advanced Export

You can use the advanced export option to export vSphere tasks that meet your specific criteria, such as status, initiator, and time range.

With the advanced export option for tasks, you can export up to 100 tasks that meet your specific criteria. You can use the exported information for monitoring and troubleshooting purposes. For example, you can export the tasks performed by specific users during the time range when some suspicious activity was detected.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Navigate to an object in the inventory.
3. Click the **Monitor** tab.
4. Under **Tasks and Events**, select **Tasks**.
5. From the **Export** drop-down menu, select **Advanced export**.

   The **Advanced Export Tasks** dialog opens.

6. Filter the tasks for which you want to export information.
   a) To export only tasks with specific status, select the respective check boxes in the **Status** options list.
   b) To export tasks based on the initiator of the tasks, select one of the options from the **Type** drop-down menu.
      - **User** - Exports tasks initiated by all users, such as `vsphere.local` users, Active Directory domain users, and system users.
      - **System** - Exports tasks initiated only by system users. System users are user accounts associated with an application or service.
   c) From the **Users** radio buttons, select whether to export the tasks initiated by specific users or by all users.

      If you select the **Specify users** radio button, you must create a list of users.

      1. From the **Domain** drop-down menu, select the domain for the users.
      2. Create a list of users who initiated the tasks.
         a. Enter a name in the Search text box.
            The system searches from the users in the selected domain.
         b. Select a user from the list and click **Add**.
   d) From the **Select time set** drop-down menu, select a time set that defines the time range of the exported tasks.

      You can select between start time, completion time, and queued time.
   e) From the **Select time range** options, select the time range for the exported tasks.
      - **Relative** - If you want to export the tasks for a relative time range, specify the relative time range from the **Last** and **Range** drop-down menus.
      - **Data range** - If you want to export the tasks for a specific time period, specify the date and time from the drop-down menus.

      For example, to export the tasks that got queued between March 13, 2022 10:30 AM and June 13, 2022 10:30 PM from the **Select time set** drop-down menu, select **Queued time**. Then select the **Date range** radio button and specify the time period using the respective text fields.
   f) From the **Include columns** radio buttons, select whether you want to export the information from all columns or from specific columns.
7. Click **Export**.

A `.csv` file is generated and available for download.

Scheduling vSphere Tasks

You can schedule vSphere tasks to run once in the future or multiple times, at a recurring interval.

The vSphere tasks that you can schedule are listed in the following table.

Table 94: Scheduled Tasks

Scheduled Task	Description
Add a host	Adds the host to the specified data center or cluster.
Change the power state of a virtual machine	Powers on, powers off, suspends, or resets the state of the virtual machine.
Change cluster power settings	Activate or deactivate DPM for hosts in a cluster.
Change resource settings of a resource pool or virtual machine	Changes the following resource settings: • CPU – Shares, Reservation, Limit. • Memory – Shares, Reservation, Limit.
Check compliance of a profile	Checks that a host's configuration matches the configuration specified in a host profile.
Clone a virtual machine	Makes a clone of the virtual machine and places it on the specified host or cluster.
Create a virtual machine	Creates a new virtual machine on the specified host.
Deploy a virtual machine	Creates a new virtual machine from a template on the specified host or cluster.

Scheduled Task	Description
Migrate a virtual machine	Migrate a virtual machine to the specified host or datastore by using migration or migration with vMotion.
Make a snapshot of a virtual machine	Captures the entire state of the virtual machine at the time the snapshot is taken.
Scan for Updates	Scans templates, virtual machines, and hosts for available updates. This task is available only when vSphere Lifecycle Manager is installed.
Remediate	Installs missing patches from the baselines selected for remediation on the hosts discovered during the scan operation and applies the newly configured settings. This task is available only when vSphere Lifecycle Manager is installed.

You create scheduled tasks by using the **Scheduled Task** wizard. For some scheduled tasks, this wizard opens the wizard used specifically for that task. For example, if you create a scheduled task that migrates a virtual machine, the **Scheduled Task** wizard opens the **Migrate Virtual Machine** wizard, which you use to set up the migration details.

Scheduling one task to run on multiple objects is not possible. For example, you cannot create one scheduled task on a host that powers on all virtual machines on that host. You must create a separate scheduled task for each virtual machine.

After a scheduled task runs, you can reschedule it to run again at another time.

> **Note:**
> At the time when a scheduled task is about to run, the user who created or last edited the task must be authenticated and authorized to run the task. If, for example, the user permissions to create or edit a scheduled task are removed, or the user account is deleted, the scheduled task fails with an error message. An administrator or a user with the required privileges can reschedule the task for subsequent runs.

How Do You Create a Scheduled vSphere Task

You can create scheduled tasks for operations that you want to run automatically once or at a recurring interval.

Required privilege: **Schedule Task** > **Create tasks**

> **Note:**
> At the time when a scheduled task is about to run, the user who created the task must still have the **Schedule Task** > **Create tasks** privileges. If the user is no longer authenticated or authorized to run the task, for example, their permissions to create a scheduled task are removed, or the user account is deleted, the scheduled task fails with an error message. An administrator or another user with the required privileges can reschedule the task for subsequent runs.

If the task to schedule is not available in the vSphere Client, use the vSphere API. See the *vSphere SDK Programming Guide*.

> **CAUTION:**
> Do not schedule multiple tasks simultaneously on the same object. The results are unpredictable.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to the object in the inventory for which you want to schedule a task.
3. Select **Configure** > **Scheduled Tasks** > **New Scheduled Task**.
4. From the **New Scheduled Task** drop-down menu, select the task to schedule.
   The **Schedule New Task** wizard opens for the task with the task name appended next to the name of the wizard. The wizard contains a page where you configure the scheduling options for the task.

5. Enter the required scheduling options for the task.
   a) Enter a name and description of the task.
   b) Choose a frequency for the task.

Option	Description
Once	Runs the scheduled task at the time selected.
After vCenter startup	Runs the task a specified number of minutes after vCenter startup.
Hourly	1. Enter the repeat frequency. 2. Enter the start date and time. 3. Enter the end date and time. For example, to start a task at the half-hour mark of every fifth hour, enter `5` hours and `30` minutes.
Daily	1. Enter the repeat frequency. 2. Enter the start date and time. 3. Enter the end date and time. For example, to run the task at 2:30 pm every four days, enter `4` and `14:30`.
Weekly	1. Enter the repeat frequency. 2. Select the day of the week. 3. Enter the start date and time. 4. Enter the end date and time. For example, to run the task at 6 am every Tuesday and Thursday, enter **1** week, **6 am**, and select **Tuesday** and **Thursday**.
Monthly	1. Enter the repeat frequency. 2. Select the days by using one of the following methods. – Enter a specific day of the month and the number of months. For example, the tenth day every five months. – Select **first**, **second**, **third**, **fourth**, or **last**, and select the day of the week and the number of months. **last** runs the task on the last week in the month that the day occurs. For example, if you select the last Monday of the month and the month ends on a Sunday, the task runs six days before the end of the month.

   c) Optional: Enter one or more email addresses to receive an email notification when the task is complete.

   To schedule some tasks, you must enter additional details for the task. For example, to schedule taking a virtual machine snapshot, the **Schedule New Task (Take Snapshot)** wizard opens. In the **Scheduling Options** page, you set the scheduling options for the task, and in the **Snapshot Settings** page, you enter the properties for the snapshot.

6. Click **Schedule the task**.

How Do You Change or Reschedule a Scheduled vSphere Task

After a scheduled vSphere task is created, you can change the schedule, frequency, and other attributes of the task. You can edit and reschedule tasks before or after they run.

Required privilege:**Schedule Task** > **Modify**

> **Note:**
> At the time when a scheduled task is about to run, the user who last edited the scheduled task must still have the **Schedule Task** > **Modify** privileges. If the user is no longer authenticated or authorized to run the task, for example, their permissions to edit a scheduled task are removed, or the user account is deleted, the scheduled task fails with a warning. An administrator or another user with the required privileges can reschedule the task for subsequent runs.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to the object in the inventory for which you want to edit a scheduled task.

   To view all scheduled tasks for a vCenter instance, navigate to that vCenter instance.
3. Select **Configure**, and select **Scheduled Tasks**.
4. Select a task from the list on the left and click **Edit**.
5. Right-click the task and select **Edit**.
6. Change the task attributes as necessary.
7. Click **Save**.

How Do You Remove a Scheduled vSphere Task

Removing a scheduled task removes all future occurrences of the task. The history associated with all completed occurrences of the task remains in the vCenter database.

Required privilege:**Scheduled task** > **Remove**

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**..
2. Navigate to the object for which you want to remove a scheduled task.

   To view all scheduled tasks for a vCenter instance, navigate to that vCenter instance.
3. Select **Configure**, and select **Scheduled Tasks**.
4. Select a task from the list on the left and click **Remove**.

vSphere Host Configuration

Before you set up your virtual environment and consider how the virtual machines that it will support are going to be used and administered, you should configure ESX hosts in vCenter.

The configuration of ESX hosts involves several tasks. Learn how to configure the boot device of the ESX host, the agent VM settings, advanced host attributes, and time configuration settings.

For information on configuring network and storage access, and security settings, see the configuration information for the specific vSphere component in the *vSphere Security* documentation, the *vSphere Storage* documentation, and the *vSphere Networking* documentation.

How to Configure the Boot Device on Your ESX Host

On servers running ESX, you can select the device that the server boots from.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a host in the inventory and click the **Configure** tab.
4. Under Hardware, select **Overview** and click the **Boot Options** button.
5. Select a boot device from the drop-down menu.
6. Optional: To reboot immediately from the device you selected, select **Apply and Reboot on OK**.
   If you do not select **Apply and Reboot on OK**, the new setting takes effect when the host reboots next.
7. Click **OK**.

How to Configure Your Agent VM Settings in the vSphere Client

In your vSphere environment, you can configure the datastore and network settings for the ESX agent virtual machines that you deploy on a host.

An ESX agent is a virtual machine, or a virtual machine and a vSphere Installation Bundle (VIB), that extend the functions of an ESX host to provide additional services that a vSphere solution requires.

For example, a solution might require a particular network filter or firewall configuration to function. A solution can use an ESX agent to connect to the vSphere Hypervisor and extend the host with functions specific to that solution. For example, the ESX agent can filter network traffic, act as a firewall, or gather other information about the virtual machines on the host.

When you configure the datastore and network settings for ESX agents on a host, all of the ESX agents that you deploy on the host use that datastore and network configuration.

> **Important:**
> ESX agents are deployed only if you configure the network and datastore settings.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a host in the inventory and click the **Configure** tab.
4. Under **Virtual Machines**, select **Agent VM Settings**.
   The current settings for the ESX agents on the host, if any, appear.
5. Click **Edit**.
6. From the **Datastore** drop-down menu, select a datastore in which to deploy the ESX agent virtual machines.
7. From the **Network** drop-down menu, select a network to connect the ESX agents.
8. Click **OK**.

For information about ESX agents and ESX Agent Manager, see *Developing and Deploying vSphere Solutions, vServices, and ESX Agents*.

Set Advanced Host Attributes

You can set advanced attributes for a host.

CAUTION:
Changing advanced options is considered unsupported. Typically, the default settings produce the optimum result. Change the advanced options only when you get specific instructions from VMware technical support or a knowledge base article.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a host in the inventory and click the **Configure** tab.
4. Under **System**, click **Advanced System Settings**.
5. Click the **Edit** button.
6. Find the appropriate item and change the value.
7. Click **OK**.

Advanced Memory Attributes

You can use the advanced memory attributes to customize memory resource usage.

Table 95: Advanced Memory Attributes

Attribute	Description	Default
Mem.ShareForceSalting	Mem.ShareForceSalting 0: Inter-virtual machine Transparent Page Sharing (TPS) behavior is still retained. The value of VMX option `sched.mem.pshare.salt` is ignored even if present. Mem.ShareForceSalting 1: By default the salt value is taken from `sched.mem.pshare.salt`. If not specified, it falls back to old TPS (inter-VM) behavior by considering salt values for the virtual machine as 0. Mem.ShareForceSalting 2: By default the salt value is taken from `sched.mem.pshare.salt` if present, or `vc.uuid`. If it does not exist, then the page sharing algorithm generates random and unique value for salting per virtual machine, which is not configurable by users.	2
Mem.SamplePeriod	Specifies the periodic time interval, measured in seconds of the virtual machine's execution time, over which memory activity is monitored to estimate working set sizes.	60
Mem.BalancePeriod	Specifies the periodic time interval, in seconds, for automatic memory reallocations. Significant changes in the amount of free memory also trigger reallocations.	15
Mem.IdleTax	Specifies the idle memory tax rate, as a percentage. This tax effectively charges virtual machines more for idle memory than for memory they are actively using. A tax rate of 0 percent defines an allocation policy that ignores working sets and allocates memory strictly based on shares. A high tax rate results in an allocation policy that allows idle memory to be reallocated away from virtual machines that are unproductively hoarding it.	75
Mem.ShareScanGHz	Specifies the maximum amount of memory pages to scan (per second) for page sharing opportunities for each GHz of available host CPU resource. For example, defaults to 4 MB/sec per 1 GHz.	4

Attribute	Description	Default
Mem.ShareScanTime	Specifies the time, in minutes, within which an entire virtual machine is scanned for page sharing opportunities. Defaults to 60 minutes.	60
Mem.CtlMaxPercent	Limits the maximum amount of memory reclaimed from any virtual machine using the memory balloon driver (`vmmemctl`), based on a percentage of its configured memory size. Specify 0 to deactivate reclamation for all virtual machines.	65
Mem.AllocGuestLargePage	Activates backing of guest large pages with host large pages. Reduces TLB misses and improves performance in server workloads that use guest large pages. 0=deactivate.	1
Mem.AllocUsePSharePool and Mem.AllocUseGuestPool	Reduces memory fragmentation by improving the probability of backing guest large pages with host large pages. If host memory is fragmented, the availability of host large pages is reduced. 0 = deactivate.	15
Mem.MemZipEnable	Activates memory compression for the host. 0 = deactivate.	1
Mem.MemZipMaxPct	Specifies the maximum size of the compression cache in terms of the maximum percentage of each virtual machine's memory that can be stored as compressed memory.	10
LPage.LPageDefragEnable	Activates large page defragmentation. 0 = deactivate.	1
LPage.LPageDefragRateVM	Maximum number of large page defragmentation attempts per second per virtual machine. Accepted values range from 1 to 1024.	32
LPage.LPageDefragRateTotal	Maximum number of large page defragmentation attempts per second. Accepted values range from 1 to 10240.	256
LPage.LPageAlwaysTryForNPT	Try to allocate large pages for nested page tables (called 'RVI' by AMD or 'EPT' by Intel). If you activate this option, all guest memory is backed with large pages in machines that use nested page tables (for example, AMD Barcelona). If NPT is not available, only some portion of guest memory is backed with large pages. 0= deactivate.	1

Advanced NUMA Attributes

You can use the advanced NUMA attributes to customize NUMA usage.

Table 96: Advanced NUMA Attributes

Attribute	Description	Default
Numa.RebalancePeriod	Controls the frequency of rebalance periods, specified in milliseconds. More frequent rebalancing can increase CPU overheads, particularly on machines with a large number of running virtual machines. More frequent rebalancing can also improve fairness.	2000
Numa.MigImbalanceThreshold	The NUMA rebalancer computes the CPU imbalance between nodes, accounting for the difference between each virtual machine’s CPU time entitlement and its actual consumption. This option controls the minimum load imbalance between nodes needed to trigger a virtual machine migration, in percent.	10
Numa.RebalanceEnable	Activate NUMA rebalancing and scheduling. Set this option to 0 to deactivate all NUMA rebalancing and initial placement of virtual machines, effectively deactivating the NUMA scheduling system.	1
Numa.RebalanceCoresTotal	Specifies the minimum number of total processor cores on the host required to activate the NUMA rebalancer.	4

Attribute	Description	Default
Numa.RebalanceCoresNode	Specifies the minimum number of processor cores per node required to activate the NUMA rebalancer. This option and Numa.RebalanceCoresTotal are useful when deactivating NUMA rebalancing on small NUMA configurations (for example, two-way Opteron hosts), where the small number of total or per-node processors can compromise scheduling fairness when you activate NUMA rebalancing.	2
Numa.AutoMemAffinity	Automatically set memory affinity for virtual machines that have CPU affinity set.	1
Numa.PageMigEnable	Automatically migrate pages between NUMA nodes to improve memory locality. Page migration rates set manually are still in effect.	1

Configuring the Time on Your ESX Host

Time synchronization on ESX hosts is the process of aligning the system clock of each host with a reliable external time source such as Network Time Protocol (NTP) or Precision Time Protocol (PTP). Accurate time on ESX hosts ensures that time-sensitive operations, including SSL certificate validation and SAML token authentication, function correctly across the vSphere network.

Unsynchronized clocks on ESX hosts can cause authentication failures, prevent the vmware-vpxd service from starting, and cause installations, migrations, or upgrades to fail. Time inconsistencies can also cause the first boot of a component in your environment to fail, depending on where in the environment the time is inaccurate and when synchronization occurs. Problems most commonly occur when the target host for a destination is not synchronized with NTP or PTP. Issues can also arise if a virtual machine migrates to a host that is set to a different time due to fully automated DRS.

vSphere supports three mechanisms for clock synchronization. To achieve optimal results, you must select the protocol that is best suited to your specific environment. For more information, see Synchronizing Clocks on the vSphere Network.

To ensure precise timestamping of events and synchronization of the time between an ESX host and the other components in the vSphere network, configure the time settings of the ESX host manually or synchronize the time and date of the host with an NTP or PTP server. For more information, see Configure the Date and Time on Your ESX Host Manually, Use PTP for Time and Date Synchronization of Your ESX Host, Use NTP Servers for Time and Date Synchronization of Your ESX Host.

Exact timestamping shows the precise sequence of events that occur in the vSphere network. Time synchronization between the components of the vSphere network can prevent authentication problems, backup issues, and incorrect logs. To ensure that all components in your environment have the correct time, as a best practice you must use the same time synchronization mechanism across the board.

Configure the Date and Time on Your ESX Host Manually

Learn how to configure the date and time of the ESX host manually in the vSphere Client. You can use the manual time configuration only after you stop synchronizing the time and date with NTP or PTP.

- Verify that the NTP and the PTP configurations are not used on the host.

If you notice some significant clock skew between a host in your environment and the rest of the vSphere components, you might need to first manually set the time and date on the host before synchronizing it to an NTP server or PTP.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a host in the inventory and click the **Configure** tab.
4. Select **System** > **Time Configuration**.
5. Click **Manual Set-Up**.

   The **Manual time configuration** dialog box appears.
6. Enter a date and time and click **OK**.

   Note:

   ESX hosts use UTC (Coordinated Universal Time) and do not support changing time zones. In the vSphere Client, you see your local time as the current host time.

Use NTP Servers for Time and Date Synchronization of Your ESX Host

To avoid time synchronization problems between an ESX host and other components in the vSphere network, you can synchronize the time and date of the host to an NTP server.

- Verify that the PTP service is not running. For information about how to change its status, see *Manage the NTP and PTP Service Status on Your ESX Host.*

The NTP and the PTP services cannot run simultaneously. Deactivate the PTP service and then enable the NTP server synchronization. Additionally, when you enable the NTP service, the manual time configuration becomes inactive.

Note:

You can set a startup policy to control the start and stop of the NTP service. You can also change the NTP service status manually. For more information about services, see *Manage the NTP and PTP Service Status on Your ESX Host*.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a host in the inventory and click the **Configure** tab.
4. Select **System** > **Time Configuration**.
5. Click **Add Service** and select **Network Time Protocol** from the drop-down menu.
6. In the **Network Time Protocol** dialog box, edit the network time protocol settings.
   a) To monitor all events in the vSphere environment, select **Enable monitoring events**.
   b) In the **NTP Servers** text box, enter the IP addresses or host names of the NTP servers that you want to use. A best practice is to use at least three NTP servers for the time synchronization of the host.
   c) Click **OK**.

   The NTP configuration is triggered immediately.

Use PTP for Time and Date Synchronization of Your ESX Host

To ensure that the time of an ESX host is synchronized with the time of other components of the vSphere network, you can synchronize the time and date of the host to PTP.

- Verify that the NTP service is not running. For information about how to change its status, see *Manage the NTP and PTP Service Status on Your ESX Host*.
- For a hardware-based timestamping, verify that you enabled PCI passthrough for a network device on the host. See the *vSphere Networking* documentation.

The Precision Time Protocol allows both software- and hardware-based timestamping on an ESX hosts and provides a highly accurate time synchronization. PTP provisions hardware-based timestamping for the virtual machines and the hosts within a network.

The PTP and the NTP services cannot run simultaneously. Stop the NTP service and then enable the PTP service. Additionally, when you enable the PTP service, the manual time configuration becomes inactive.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a host in the inventory and click the **Configure** tab.
4. On the **Configure** tab, select **System** > **Time Configuration**.
5. Click **Add Service** and select **Precision Time Protocol** from the drop-down menu.
6. In the **Precision Time Protocol** dialog box, edit the PTP settings.
   a) Select the PTP-enabled network device for time synchronization from the **Network adapter type** drop-down menu.

PCI passthrough	For configuring a hardware timestamping with a PCI passthrough network device, follow these steps: 1. From the **Device name** drop-down menu, select the PCI passthrough network device. For vSphere 7.0 U3, the supported network adapters are IntelX710 and E810. 2. Enter the IP configuration settings for the network device. – To use DHCP to obtain the IP address configuration of the network device, select **Obtain IPv4 settings automatically**. – To set a static IP configuration, select the **Use static IPv4 settings** option and enter the IPv4 configuration settings. – To use the IEEE 802.3 network transport, select **No IP configuration (use IEEE 802.3 transport)**.
VMkernel Adapter	For configuring software timestamping PTP, from the **Device name** drop-down menu, select the VMkernel adapter configured to use PTP.

7. Optional: Create a fallback mechanism in case the PTP synchronization fails.
   a) To monitor the events in vSphere, select the **Enable monitoring events** check box.
   b) To enable a fallback mechanism in case PTP become inaccessible, click **Enable fallback**.

      You can create a fallback mechanism only if you enabled tracking the events in vSphere.
   c) In the **NTP Servers** text box, enter the IP addresses or host names of the NTP servers that you want to use. A best practice is to use at least three NTP servers for the time synchronization of the host.
8. Click **OK**.

   Finishing the configuration immediately triggers the PTP synchronization.
9. Optional: To test whether the service used for time synchronization of the host is running correctly, click **Test Services**.

   The **Time Synchronization Services test** dialog box appears. You can see information about how the activated time configuration works by collecting information from various systems.

Manage the NTP and PTP Service Status on Your ESX Host

In the vSphere Client, you can configure a startup policy for the NTP or PTP service that runs on the ESX host. You can also manually start, stop, or restart the respective service and in this way override the configured startup policy.

1. In the vSphere Client, click the main navigation menu

   (**),** and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a host in the inventory and click the **Configure** tab.
4. Select **System** > **Services**.
5. Change the status of the NTP or PTP service manually.

Option	Description
Option	Action
Change the NTP service status	1. Select **NTP Daemon**. 2. Click **Start**, **Stop**, or **Restart**.
Change the PTP service status	1. Select **PTP Daemon**. 2. Click **Start**, **Stop**, or **Restart**.

6. Optional: Select the NTP or PTP service and click **Edit Startup Policy**.

Option	Description
Start and stop with port usage	Starts or stops the service when a client port is activated or deactivated for access to the security profile of the host.
Start and stop with host	Starts and stops the service when the host powers on and shuts down.
Start and stop manually	You must manually control the status of the service.

Delete a Time Synchronization Service on Your ESX Host

Read how to delete a time synchronization service that is no longer needed by using the vSphere Client.

Verify that the service you want to delete is not used to synchronize the time of the host.

1. In the vSphere Client, click the main navigation menu

   (**),** and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select a host in the inventory and click the **Configure** tab.
4. Select **System** > **Time Configuration**.
5. Select the **Precision Time Protocol** or **Network Time Protocol** check box and click **Delete**.
6. Click **OK**.

Managing Hosts in the vSphere Client

To monitor all hosts in your vSphere environment from one place and to simplify host configuration, add the hosts to a vCenter instance.

The Managing Hosts in the vCenter section of the vCenter and Host Management publication explains the lifecycle and administrative tasks that you can perform on the ESX hosts that a vCenter instance manages.

You can disconnect and reconnect a managed host to temporarily suspend monitoring without removing the host or its virtual machines from the inventory, or remove a host to delete it and its associated virtual machines entirely.

The section also describes how to relocate an ESX host between vCenter instances, reboot or shut down a host, verify SSL certificates for legacy hosts, and enable SGX remote attestation on multi-socket hosts.

For information about the configuration management of ESX hosts, also see the vSphere Networking, vSphere Storage, and vSphere Security documentation.

Disconnecting and Reconnecting an ESX Host

You can disconnect and reconnect a host that a vCenter system manages. Disconnecting a managed host does not remove it from vCenter, but temporarily suspends all monitoring activities that vCenter performs.

The managed host and its associated virtual machines remain in the vCenter inventory. By contrast, removing a managed host from vCenter deletes the managed host and all its associated virtual machines from the vCenter inventory.

If an ESX host becomes disconnected due to a loss of network connectivity to vCenter, the ESX host reconnects automatically to vCenter after network connectivity is restored. If you manually disconnect an ESX host, see How to Reconnect Your Managed ESX Host for more information.

Reconnecting an ESX host automatically or manually does not impact the running virtual machines, unless the host is part of a cluster and there are resource pool privileges configured. For more information about creating and managing resource pools, see the *vSphere Resource Management* documentation.

How to Disconnect Your Managed ESX Host

Use the vSphere Client to disconnect a managed host from vCenter.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and select a host.
3. Right-click the host and select **Connection** > **Disconnect** from the pop-up menu.
4. In the confirmation dialog box that appears, click **Ok**.
   If the managed host is disconnected, the word “disconnected” is appended to the object name in parentheses, and the object is dimmed. All associated virtual machines are similarly dimmed and labeled.

How to Reconnect Your Managed ESX Host

Use the vSphere Client to reconnect a managed host to a vCenter system.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and select a host.
3. Right-click the host and select **Connection** > **Connect** from the pop-up menu.
   When the managed host’s connection status to vCenter is changed, the statuses of the virtual machines on that managed host are updated to reflect the change.

How Do You Reconnect ESX Hosts After Changes to the vCenter SSL Certificate

vCenter uses an SSL certificate to encrypt and decrypt host passwords stored in the vCenter database. If the certificate is replaced or changed, vCenter cannot decrypt host passwords, and therefore cannot connect to managed hosts. If vCenter fails to decrypt a host password, the host is disconnected from vCenter.

You must reconnect the host and supply the login credentials, which are encrypted and stored in the database using the new certificate.

Rename an ESX Host FQDN

Starting with vSphere 9.0, you can change the FQDN of an ESX host at any time. You do not need to disconnect the host, or put it in maintenance mode.

- Verify that the ESX host, and the vCenter instance are version 9.0 or later.
- Verify that you have the Host.Config.Settings privilege.
- Verify that the current ESX host FQDN remains valid until the rename task is complete.
- Verify that the new ESX host FQDN is registered with your DNS provider.
- If you manage your certificates, verify that the current and the new host FQDNs are present in the host certificate as Subject Alternative Name (SAN).

For example, you can change the host FQDN if you need to change the network configuration.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Right-click the host, and select **Rename**.
4. On the **Rename Host** page, select the check boxes to verify that you meet the prerequisites.
5. In the New host FQDN field, enter the name of the host, and click **Rename Host**.

You can check the task progress in the **Recent Tasks** pane. When the task is complete, the new host name appears in the inventory list.

How to Relocate Your ESX Host

You can move a host to another location within the vSphere inventory by dragging the host to the new location. The new location can be a folder, a cluster, or you can place the host as a standalone object in the data center.

Power off all virtual machines that are running on the host, or migrate the virtual machines to a new host by using vMotion.

When a host is moved from a cluster to another destination in the vSphere inventory, the resources which the host provides are deducted from the total cluster resources. You can either keep the virtual machines in the same cluster and migrate them to other hosts, or keep them on the host and remove them from the cluster. For information about removing a host from a cluster, see Removing a Host from a Cluster in the *vSphere Resource Management* documentation.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and select a host.
3. If the host is part of a cluster, put it in maintenance mode.
   a) Right-click the host and select **Maintenance Mode** > **Enter Maintenance Mode**.
   b) Optional: If the host is part of a DRS cluster, evacuate the powered off or suspended virtual machines to other hosts within the cluster by selecting the check box **Move powered-off and suspended virtual machines to other hosts in the cluster**.
   c) In the confirmation dialog box, click **OK**.
      The host enters maintenance mode.
4. Select the host in the vSphere inventory panel and drag it to the new location within the inventory.
5. Right-click the host and select **Maintenance Mode** > **Exit Maintenance Mode**.
6. Optional: Power on the virtual machines that you powered off before you put the host in maintenance mode.

How to Remove an ESX Host from Your vCenter Instance

Remove a managed host from vCenter to stop vCenter from monitoring and managing that host.

- Make sure that NFS mounts are active. If NFS mounts are unresponsive, the operation fails.
- If the host you want to remove from the cluster is connected to a distributed switch, remove the host from the switch. For more information, see Remove Hosts from a vSphere Distributed Switch in the *vSphere Networking* documentation.

If possible, remove managed hosts while they are connected. Removing a disconnected host does not remove the vCenter agent from the managed host.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and select a host.
3. Optional: If the host is part of a cluster, put it in maintenance mode.
   a) Right-click the host and select **Maintenance Mode** > **Enter Maintenance Mode** from the pop-up menu.
      If not all virtual machines on the host are powered off, the host does not enter maintenance mode.

      If the host is part of a DRS cluster, when the host enters maintenance mode, DRS attempts to evacuate powered on virtual machines from the host by using vMotion.
   b) In the confirmation dialog box, click **Ok**.
      If the host is part of a DRS cluster, you can evacuate powered off or suspended virtual machines to other hosts within the cluster. Select the check box **Move powered-off and suspended virtual machines to other hosts in the cluster**.

      The host icon changes and the term Maintenance Mode is added to the name in parentheses.
4. Right-click the host you want to remove in the inventory pane, and select **Remove from Inventory** from the pop-up menu.
5. In the confirmation dialog box, click **Yes** to remove the host.
   vCenter removes the host and the associated virtual machines from the vCenter instance. vCenter then returns the status of all associated processor and migration licenses to available.

How to Reboot or Shut Down Your ESX Host

You can power off or restart any ESX host using the vSphere Client. Powering off a managed host disconnects it from vCenter, but does not remove it from the inventory.

- Power off all virtual machines that are running on the host, or migrate the virtual machines to a new host by using vMotion.
- Put the host in maintenance mode.

To shut down or reboot an ESX host, you can use the ESXCLI command set. See the *Stopping and Rebooting Hosts with ESXCLI* topic in the *ESXCLI Concepts and Examples* documentation at https://developer.broadcom.com/tools/esxcli/latest.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and select a host.
3. From the **Actions** menu, select **Power**.
4. Select the operation.
   - To power off and restart the ESX host, click **Reboot**.
   - To power off the ESX host, click **Shut Down**.
5. Provide a reason for the operation and click **OK**.
   This information is added to the log file.

How Do You Verify SSL Certificates for Legacy ESX Hosts

You can configure vCenter to check the SSL certificates of hosts to which it connects. If you configure this setting, vCenter and the vSphere Client check for valid SSL certificates before connecting to a host for operations such as adding a host or making a remote console connection to a virtual machine.

SSL certificates are signed by VMware Certificate Authority by default. You can instead use certificates from a third-party CA. Thumbprint mode is supported only for legacy hosts.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and navigate to the vCenter instance.
3. Select the **Configure** tab.
4. Under **Settings**, select **General**.
5. Click **Edit**.
6. Select **SSL settings**.
7. Determine the host thumbprint for each legacy host that requires validation.
   a) Log in to the direct console.
   b) Select **View Support Information** on the **System Customization** menu.
      The thumbprint is displayed in the column on the right.
8. Compare the thumbprint you obtained from the host with the thumbprint listed in the vCenter SSL settings dialog box.
9. If the thumbprints match, select the check box for the host.
   Hosts that are not selected will be disconnected after you click **Save**.

10. Click **Save**.

Enabling SGX Remote Attestation on Multi-Socket ESX Hosts

Intel® Software Guard Extensions (Intel® SGX) is a hardware-based security solution that allows you to isolate specific application code and data in private memory regions, called enclaves. Use the vSphere Client to register your SGX-capable hosts with multiple CPU sockets with the Intel Registration Server and use remote attestation for applications running inside your vSGX-enabled virtual machines.

You can enable the Virtual Intel® Software Guard Extensions (vSGX) on virtual machines and provide additional security to your workloads. See Securing Virtual Machines with Intel Software Guard Extensions in the *vSphere Security* documentation. Furthermore, you can use remote attestation for the vSGX-enabled virtual machines. Intel SGX remote attestation is a security mechanism that allows you to establish an authenticated and secure communication channel with a trusted remote entity. To use remote attestation for virtual machines using SGX enclaves, hosts with a single CPU socket do not require Intel registration.

Starting with vSphere 8.0, to enable the remote attestation on a virtual machine running on a host with multiple CPU sockets, you must first register the host with the Intel Registration Server. If an SGX-capable host with multiple CPU sockets is not registered with the Intel Registration Server, you can only power on vSGX-enabled virtual machines that do not require remote attestation.

When you add a host with SGX-capable CPUs, vCenter accesses the Unified Extensible Firmware Interface (UEFI) variables provided by the BIOS and reads the current registration status of the host. To enable vCenter to retrieve information about the SGX status of a host, you must set the firmware boot mode of the host to UEFI mode. See How to View the SGX Registration Status of Your ESX Host.

You can change the current SGX registration status of the host by using the registration options in vSphere Client or by rebooting the ESX host after microcode updates and adding or replacing a CPU package. After each host reboot, you can view the updated registration status of the host by using the vSphere Client.

SGX Registration Statuses of a Host

You can view the current status of an SGX-capable hosts using the vSphere Client and perform the necessary steps to register the hosts with the Intel Registration Server.

SGX Registration Status	Description
Not Applicable	SGX-capable hosts with a single CPU socket do not require registration with the Intel Registration Server to enable remote attestation.
Incomplete	The registration status is incomplete in one of the following use cases: • When you add a new host to a vCenter instance and the host is not registered yet. • After a host firmware update that performs an Intel SGX Trusted Computing Base (TCB) recovery. • For hosts which have multiple CPU packages, when a CPU package is added or replaced, you must manually perform an SGX factory reset on BIOS setup. Then the host must be registered as if a newly added host. • When you manually perform an SGX factory reset on the BIOS setup, you must register the host again.
Complete	The host is successfully registered with the Intel Registration Server.

How to View the SGX Registration Status of Your ESX Host

You can view the current SGX registration status of an ESX host by using the vSphere Client.

- Make sure that the host is installed on an Intel CPU with SGX capabilities and SGX is enabled.
- Set the firmware boot mode of the host to UEFI.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and select an SGX-capable host from the inventory.
3. On the **Summary** tab, navigate to the **Hardware** card.
4. Expand the **SGX** node to view the value of the Registration Status property.

   For more information about the different registration statuses, see Enabling SGX Remote Attestation on Multi-Socket ESX Hosts.

To use the remote attestation feature for vSGX-enabled virtual machines, you must register the host with the Intel Registration Server if the host registration is incomplete and the host has multiple CPU sockets. See How to Register Your Multi-Socket ESX Host with the Intel SGX Registration Server.

How to Register Your Multi-Socket ESX Host with the Intel SGX Registration Server

To use the SGX remote attestation feature for a multi-socket host, register the ESX host with the Intel Registration Server using the vSphere Client.

- Make sure that the host is installed on an Intel CPU with SGX capabilities and SGX is enabled.
- Set the firmware boot mode of the host to UEFI.

The Intel SGX attestation mechanism ensures the trust between the vSGX enclave and an external entity. To use this feature on a multi-socket host with enabled SGX capabilities, you must register the host with the Intel SGX Registration Server.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Select an SGX-capable host from the inventory, and click the **Configure** tab.
4. Under Hardware, select **SGX** and click **Register**.

Upon successful completion of the registration operation, the registration status of the host changes to Completed.

Enable remote attestation for a vSGX-enabled virtual machine. See Securing Virtual Machines with Intel Software Guard Extensions in the *vSphere Security* documentation.

vSphere Virtual Machines Migration

With vSphere vMotion, you can move virtual machines from one compute resource or storage location to another by using cold or hot migration.

For example, with vSphere vMotion you can move powered on virtual machines away from a host to perform maintenance, to balance loads, to collocate virtual machines that communicate with each other, to move virtual machines apart to minimize fault domain, to migrate to new server hardware, and so on.

Moving a virtual machine from one inventory folder to another folder or resource pool in the same data center is not a form of migration. Unlike migration, cloning a virtual machine or copying its virtual disks and configuration file in the same vCenter system are procedures that create a new virtual machine. Cloning and copying a virtual machine in the same vCenter system are also not forms of migration.

By using migration, you can change the compute resource that the virtual machine runs on. For example, you can move a virtual machine from one host to another host or cluster.

To migrate virtual machines with disks larger than 2 TB, the source and destination ESX hosts must be version 6.0 and later.

Depending on the power state of the virtual machine that you migrate, migration can be cold or hot.

Cold Migration	Moving a powered off or suspended virtual machine to a new host. Optionally, you can relocate configuration and disk files for powered off or suspended virtual machines to new storage locations. You can also use cold migration to move virtual machines from one virtual switch to another, and from one data center to another. You can perform cold migration manually or you can schedule a task.
Hot Migration	Moving a powered on virtual machine to a new host. Optionally, you can also move the virtual machine disks or folder to a different datastore. Hot migration is also called live migration or vSphere vMotion. With vSphere vMotion, you migrate the virtual machine without any interruption in its availability.

Depending on the virtual machine resource type, you can perform three types of migration.

Change compute resource only	Moving a virtual machine, but not its storage, to another compute resource, such as a host, cluster, resource pool, or vApp. You can move the virtual machine to another compute resource by using cold or hot migration. If you change the compute resource of a powered on virtual machine, you use vSphere vMotion.
Change storage only	Moving a virtual machine and its storage, including virtual disks, configuration files, or a combination of these, to a new datastore on the same host. You can change the datastore of a virtual machine by using cold or hot migration. If you move a powered on virtual machine and its storage to a new datastore, you use Storage vMotion.
Change both compute resource and storage	Moving a virtual machine to another host and at the same time moving its disk or virtual machine folder to another datastore. You can change the host and datastore simultaneously by using cold or hot migration.

You can move virtual machines between vSphere sites by using migration between the following types of objects.

Migrate to another virtual switch	Moving the network of a virtual machine to a virtual switch of a different type. You can migrate virtual machines without reconfiguring the physical and virtual network. By using cold or hot migration, you can move the virtual machine from a standard to a standard or distributed switch, and from a distributed switch to another distributed switch. When you move a virtual machine network between distributed switches, the network configuration and policies that are associated with the network adapters of the virtual machine are transferred to the target switch.
Migrate to another data center	Moving a virtual machine to a different data center. You can change the data center of a virtual machine by using cold or hot migration. For networking in the target data center, you can select a dedicated port group on a distributed switch.
Migrate to another vCenter system	Moving a virtual machine to a different vCenter instance. You can move a virtual machine to a vCenter instance that is connected to the source vCenter instance through vCenter linking. You can also move virtual machines between vCenter instances that are located across a long distance from each other. Starting with vSphere 7.0 Update 1c, you can migrate workloads across vCenter systems by using Advanced Cross vCenter vMotion. You can initiate migration of workloads both from on-premise environments and from cloud environments. Advanced Cross vCenter vMotion does not depend on vCenter linking and you can migrate virtual machines across vCenter systems in different vCenter Single Sign-On domains. Starting with vSphere 7.0 Update 3, you can use the Advanced Cross vCenter vMotion feature to clone virtual machines across vCenter systems.

Starting with vSphere 9.0, you can migrate the virtual machines to the vSphere Supervisor. For more information, see Import VMs into vSphere Supervisor.

Cold Migration in Your vSphere Environment

Cold migration is the migration of powered off or suspended virtual machines between hosts across clusters, data centers, and vCenter instances. By using cold migration, you can also move associated disks from one datastore to another.

You can use cold migration to have the target host checked against fewer requirements than when you use vMotion. For example, if you use cold migration when a virtual machine contains a complex application setup, the compatibility checks during vMotion might prevent the virtual machine from moving to another host.

You must power off or suspend the virtual machines before you begin the cold migration process. Migrating a suspended virtual machine is considered a cold migration because although the virtual machine is powered on, it is not running.

Migrating a virtual machine across its network subnets might result in the loss of network connectivity.

CPU Compatibility Check During Cold Migration

If you attempt to migrate a powered off virtual machine that is configured with a 64-bit operating system to a host that does not support 64-bit operating systems, vCenter generates a warning. Otherwise, CPU compatibility checks do not apply when you migrate powered off virtual machines with cold migration.

When you migrate a suspended virtual machine, the new host for the virtual machine must meet CPU compatibility requirements. This requirement allows the virtual machine to resume execution on the new host.

Operations During Cold Migration

A cold migration consists of the following operations:

1. If you select the option to move to a different datastore, the configuration files, including the NVRAM file (BIOS settings), log files, and the suspend file, are moved from the source host to the destination host's associated storage area. You can choose to move the virtual machine's disks as well.
2. The virtual machine is registered with the new host.
3. After the migration is completed, the old version of the virtual machine is deleted from the source host and datastore if you selected the option to move to a different datastore.

Network Traffic for Cold Migration

By default, data for VM cold migration, cloning, and snapshots is transferred through the management network. This traffic is called provisioning traffic. It is not encrypted but uses run-length encoding of data.

On a host, you can dedicate a separate VMkernel network adapter to the provisioning traffic, for example, to isolate this traffic on another VLAN. On a host, you can assign no more than one VMkernel adapter for provisioning traffic. For information about enabling provisioning traffic on a separate VMkernel adapter, see Setting Up VMkernel Networkingin the *vSphere Networking* documentation.

If you plan to transfer high volumes of virtual machine data that the management network cannot accommodate, redirect the cold migration traffic on a host to the TCP/IP stack that is dedicated to cold migration and cloning of powered off virtual machines. You can also redirect if you want to isolate cold migration traffic in a subnet different from the management network, for example, for migration over a long distance. See How to Place Traffic for Cold Migration, Cloning, and Snapshots on the Provisioning TCP/IP Stack.

How to Migrate a Powered Off or Suspended Virtual Machine

You can use cold migration to move a virtual machine and its associated disks from one datastore to another in your vSphere environment. The virtual machines are not required to be on shared storage.

- Make sure that you are familiar with the requirements for cold migration. See Cold Migration in Your vSphere Environment.
- Required privilege:**Resource** > **Migrate powered off virtual machine**

1. In the vSphere Client, click the main navigation menu

   (**),** and select **Inventory**.
2. Navigate to **Hosts and Clusters**, and navigate to the virtual machine.
3. Power off or suspend the virtual machine.
4. Right-click the virtual machine and select **Migrate**.
   a) To locate a virtual machine, select a data center, folder, cluster, resource pool, host, or vApp.
   b) Click the **Virtual Machines** tab.
5. Select the migration type and click **Next**.

Option	Description
Change compute resource only	Move the virtual machine to another host.
Change storage only	Move the virtual machine's configuration file and virtual disks.
Change both compute resource and storage	Move the virtual machine to another host and move its configuration file and virtual disks.

6. If you change the compute resource of the virtual machine, select the destination compute resource for this virtual machine migration and click **Next**.

   Any compatibility problem appears in the Compatibility panel. Fix the problem, or select another host or cluster.

   Possible targets include hosts and DRS clusters with any level of automation. If a cluster has no DRS enabled, select a specific host in the cluster rather than selecting the cluster.

   Important:

   If the virtual machine that you migrate has an NVDIMM device and uses PMem storage, the destination host or cluster must have available PMem resources. Otherwise, the compatibility check fails and you cannot proceed further with the migration.

   If the virtual machine that you migrate does not have an NVDIMM device but it uses PMem storage, you must select a host or cluster with available PMem resources, so that all PMem hard disks remain stored on a PMem datastore. Otherwise, all the hard disks use the storage policy and datastore selected for the configuration files of the virtual machine.

   Important:

   Migrating a virtual machine that has an NVDIMM device or a vPMem disk to a host that does not have the proper license fails and leaves the virtual machine in an unmanageable state for 90 seconds. You can afterwards retry the migration and select a destination host that is licensed to use PMem devices.
7. If you change the storage of the virtual machine, enter the required details in the **Select Storage** page.
   a) Select the storage type for the virtual machine configuration files and all the hard disks.
      - If you select the **Standard** mode, all virtual disks are stored on a standard datastore.
      - If you select the **PMem** mode, all virtual disks are stored on the host-local PMem datastore. Configuration files cannot be stored on a PMem datastore and you must additionally select a regular datastore for the configuration files of the virtual machine.
      - If you select the **Hybrid** mode, all PMem virtual disks remain stored on a PMem datastore. Non-PMem disks are affected by your choice of a VM storage policy and datastore or datastore cluster.

   Selecting the type of storage is possible only if PMem or Hybrid storage types are available in the data center.

b) Select the format for the virtual machine's disks.

Option	Action
Same format as source	Use the same format as the source virtual machine.
Thick Provision Lazy Zeroed	Create a virtual disk in a default thick format. Space required for the virtual disk is allocated during creation. Any data remaining on the physical device is not erased during creation. Instead, it is zeroed out on demand on first write from the virtual machine.
Thick Provision Eager Zeroed	Create a thick disk that supports clustering features such as Fault Tolerance. Space required for the virtual disk is allocated at creation time. In contrast to the thick provision lazy zeroed format, the data remaining on the physical device is zeroed out during creation. It might take longer to create disks in this format than to create other types of disks.
Thin Provision	Use the thin provisioned format. At first, a thin provisioned disk uses only as much datastore space as the disk initially needs. If the thin disk needs more space later, it can expand to the maximum capacity allocated to it.

c) Select a virtual machine storage policy from the **VM Storage Policy** drop-down menu.

Storage policies specify storage requirements for applications that run on the virtual machine. You can also select the default policy for vSAN or Virtual Volumes datastores.

Important:

If the virtual machine hard disks use different storage policies, the new policy that you select only applies to non-PMem hard disks. PMem hard disks are migrated to the host-local PMem datastore of the destination host.

d) Select the datastore location where you want to store the virtual machine files.

Option	Action
Store all virtual machine files in the same location on a datastore.	Select a datastore from the list and click **Next**.
Store all virtual machine files in the same Storage DRS cluster.	1. Select a Storage DRS cluster. 2. To deactivate Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 3. Click **Next**.
Store virtual machine configuration files and disks in separate locations.	1. Click **Configure per disk**. **Note:** You can use the **Configure per disk** option to downgrade from or upgrade to PMem storage. 2. For the virtual machine configuration file and for each virtual disk, select **Browse**, and select a datastore or Storage DRS cluster. **Note:** Configuration files cannot be stored on a PMem datastore. 3. If you selected a Storage DRS cluster and do not want to use Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 4. Click **Next**.

8. If you change the compute resource of the virtual machine, select destination networks for the virtual machine migration.

   You can migrate a virtual machine network to another distributed switch in the same or to another data center or vCenter.

Option	Action
Select a destination network for all VM network adapters connected to a valid source network.	1. Click the arrow in the **Destination Network** column and select **Browse**. 2. Select a destination network and click **OK**. 3. Click **Next**.
Select a new destination network for each VM network adapter connected to a valid source network.	1. Click **Advanced**. 2. Click the arrow in the **Destination Network** column and select **Browse**. 3. Select a destination network and click **OK**. 4. Click **Next**.

9. On the **Ready to complete** page, review the details and click **Finish**.

vCenter moves the virtual machine to the new host or storage location.

Event messages appear in the **Events** tab. The data displayed on the **Summary** tab shows the status and state throughout the migration. If errors occur during migration, the virtual machines revert to their original states and locations.

Migrating Virtual Machines with vSphere vMotion

If you must take a host offline for maintenance, you can move the virtual machine to another host. Migration with vSphere vMotion allows virtual machine processes to continue working throughout a migration.

When you migrate a virtual machine with vSphere vMotion, the new host for the virtual machine must meet compatibility requirements so that the migration can proceed.

For more information about the vMotion migration types, see vSphere Virtual Machines Migration.

Transferred State Information

The state information includes the current memory content and all the information that defines and identifies the virtual machine. The memory content includes transaction data and the bits of the operating system and applications that are in the memory. The defining and identification information stored in the state includes all the data that maps to the virtual machine hardware elements. This information includes BIOS, devices, CPU, MAC addresses for the Ethernet cards, chipset states, registers, and so forth.

Stages in vSphere vMotion

Migration with vSphere vMotion occurs in three stages:

1. When you initiate a migration with vSphere vMotion, vCenter verifies that the existing virtual machine is in a stable state within its current host.
2. The virtual machine state information (memory, registers, and network connections) is copied to the target host.
3. The virtual machine resumes its activities on the new host.

If errors occur during migration, the virtual machine reverts to its original state and location.

Host Configuration for vSphere vMotion

Before using vSphere vMotion, you must configure your hosts correctly.

- Each host must be licensed.

- Each host must meet shared storage requirements for vSphere vMotion. See vSphere vMotion Shared Storage Requirements.
- Each host must meet the networking requirements for vSphere vMotion. See What Are the vSphere vMotion Networking Requirements.

vSphere vMotion Across Long Distances

You can perform reliable migrations between hosts and sites that are separated by high network round-trip latency times. No user configuration is necessary.

For long-distance migration, verify the network latency between the hosts and your license.

- The round-trip time between the hosts must be up to 150 milliseconds.
- You must place the traffic related to transfer of virtual machine files to the destination host on the provisioning TCP/IP stack. See How to Place Traffic for Cold Migration, Cloning, and Snapshots on the Provisioning TCP/IP Stack.

vSphere vMotion Shared Storage Requirements

Configure your hosts for vSphere vMotion with shared storage to ensure that virtual machines are accessible to both source and target hosts.

During a migration with vMotion, the migrating virtual machine must be on storage accessible to both the source and target hosts. Ensure that the hosts configured for vMotion use shared storage. Shared storage can be on a Fibre Channel storage area network (SAN), or can be implemented using iSCSI and NAS.

If you use vMotion to migrate virtual machines with raw device mapping (RDM) files, make sure to maintain consistent LUN IDs for RDMs across all participating hosts.

For information about SANs and RDMs, see the *vSphere Storage* documentation.

What Are the vSphere vMotion Networking Requirements

Migration with vMotion requires correctly configured network interfaces on source and target hosts.

Configure each host with at least one network interface for vMotion traffic. To ensure secure data transfer, the vMotion network must be a secure network, accessible only to trusted parties. Additional bandwidth significantly improves vMotion performance. When you migrate a virtual machine with vMotion without using shared storage, the contents of the virtual disk is transferred over the network as well.

Network traffic with vMotion can be encrypted. Encrypted vMotion depends on host configuration, or on compatibility between the source and destination hosts.

Requirements for Concurrent vMotion Migrations

You must ensure that the vMotion network has at least 250 Mbps of dedicated bandwidth per concurrent vMotion session. Greater bandwidth lets migrations complete more quickly. Gains in throughput resulting from WAN optimization techniques do not count towards the 250-Mbps limit.

To determine the maximum number of concurrent vMotion operations possible, see vCenter Limits on Simultaneous Migrations. These limits vary with a host link speed to the vMotion network.

Round-Trip Time for Long-Distance vMotion Migration

You can perform reliable migrations between hosts that are separated by high network round-trip latency times. The maximum supported network round-trip time for vMotion migrations is 150 milliseconds. This round-trip time lets you migrate virtual machines to another geographical location at a longer distance.

Multiple-NIC vMotion

You can configure multiple NICs for vMotion by adding two or more NICs to the required standard or distributed switch. For more information, see Broadcom Knowledge Base article 318899.

Network Configuration

Configure the virtual networks on vMotion enabled hosts as follows:

- On each host, configure a VMkernel port group for vMotion.
  To have the vMotion traffic routed across IP subnets, enable the vMotion TCP/IP stack on the host. See How to Place vSphere vMotion Traffic on the vMotion TCP/IP Stack of Your ESX Host.
- If you are using standard switches for networking, ensure that the network labels used for the virtual machine port groups are consistent across hosts. During a migration with vMotion, vCenter assigns virtual machines to port groups based on matching network labels.

  Note:

  By default, you cannot use vMotion to migrate a virtual machine that is attached to a standard switch with no physical uplinks configured, even if the destination host also has a no-uplink standard switch with the same label.

  To override the default behavior, set the `config.migrate.test.CompatibleNetworks.VMOnVirtualIntranet` advanced settings of vCenter to `false`. The change takes effect immediately. For information about configuring advanced settings of vCenter, see *vCenter Configuration*.
- If you use Intrusion Detection Systems (IDS) and firewalls to protect your environment, make sure that you configure them to allow connections to the ports used for vMotion on the ESX hosts. For the list of currently supported ports for vMotion, see the VMware Ports and Protocols Tool™ at https://ports.esp.vmware.com/home/vSphere.

For information about configuring the vMotion network resources, see Networking Best Practices for vSphere vMotion .

For more information about vMotion networking requirements, see Broadcom Knowledge Base article 342209.

Networking Best Practices for vSphere vMotion

Consider certain best practices for configuring the network resources for vMotion on an ESX host.

- Provide the required bandwidth in one of the following ways:

Physical Adapter Configuration	Best Practices
Dedicate at least one adapter for vMotion.	Use at least one 10 GbE adapter for workloads that have a small number of memory operations, or if you migrate workloads that have many memory operations. If only two Ethernet adapters are available, for best availability, combine both adapters into a team, and use VLANs to divide traffic into networks: one or more for virtual machine traffic and one for vMotion.
Direct vMotion traffic to one or more physical NICs that have high-bandwidth capacity and are shared between other types of traffic as well	• To distribute and allocate more bandwidth to vMotion traffic across several physical NICs, use multiple-NIC vMotion. • On a vSphere Distributed Switch 5.1 and later, use vSphere Network I/O Control shares to guarantee bandwidth to outgoing vMotion traffic. Defining shares also prevents from contention as a result from excessive vMotion or other traffic. • To avoid saturation of the physical NIC link as a result of intense incoming vMotion traffic, use traffic shaping in egress direction on the vMotion port group on the destination host. By using traffic shaping you can limit the average and peak bandwidth available to vMotion traffic, and reserve resources for other traffic types. • In vSphere 7.0 Update 1 or earlier, vMotion saturates 1 GbE and 10 GbE physical NICs with a single vMotion VMkernel NIC. Starting with vSphere 7.0 Update 2, vMotion saturates high speed links such as 25 GbE, 40 GbE and 100 GbE with a single vMotion VMkernel NIC. If you do not have dedicated uplinks for vMotion, you can use Network I/O Control to limit vMotion bandwidth use.

- Use jumbo frames for best vMotion performance.
  Ensure that jumbo frames are enabled on all network devices that are on the vMotion path including physical NICs, physical switches, and virtual switches.
- Place vMotion traffic on the vMotion TCP/IP stack for migration across IP subnets that have a dedicated default gateway that is different from the gateway on the management network. See How to Place vSphere vMotion Traffic on the vMotion TCP/IP Stack of Your ESX Host.

Virtual Machine Conditions and Limitations for vSphere vMotion

To migrate virtual machines with vMotion, the virtual machine must meet certain network, disk, CPU, USB, and other device requirements.

The following virtual machine conditions and limitations apply when you use vSphere vMotion:

- The source and destination management network IP address families must match. You cannot migrate a virtual machine from a host that is registered to vCenter with an IPv4 address to a host that is registered with an IPv6 address.
- Using 1 GbE network adapters for the vSphere vMotion network might result in migration failure, if you migrate virtual machines with large vGPU profiles. Use 10 GbE network adapters for the vSphere vMotion network.
- If virtual CPU performance counters are enabled, you can migrate virtual machines only to hosts that have compatible CPU performance counters.
- You can migrate virtual machines that have 3D graphics enabled. If the 3D Renderer is set to Automatic, virtual machines use the graphics renderer that is present on the destination host. The renderer can be the host CPU or a GPU graphics card. To migrate virtual machines with the 3D Renderer set to Hardware, the destination host must have a GPU graphics card.
- Starting with vSphere 6.7 Update 1 and later, vSphere vMotion supports virtual machines with vGPU.
- vSphere DRS supports initial placement of vGPU virtual machines running vSphere 6.7 Update 1 or later without load balancing support.
- You can migrate virtual machines with USB devices that are connected to a physical USB device on the host. You must enable the devices for vSphere vMotion.
- You cannot use migration with vSphere vMotion to migrate a virtual machine that uses a virtual device backed by a device that is not accessible on the destination host. For example, you cannot migrate a virtual machine with a CD drive backed by the physical CD drive on the source host. Disconnect these devices before you migrate the virtual machine.
- You cannot use migration with vSphere vMotion to migrate a virtual machine that uses a virtual device backed by a device on the client computer. Disconnect these devices before you migrate the virtual machine.

Using vSphere vMotion to Migrate vGPU Virtual Machines

You can use vMotion to perform a live migration of NVIDIA vGPU-powered virtual machines without causing data loss. Starting with vSphere 8.0 Update 3, vMotion for vGPU virtual machines is activate by default.

Stun time is the time when the virtual machine is inaccessible to users during vMotion. During the stun time, you are unable to access the VM, desktop, or application. After the migration is complete, access to the virtual machine resumes and all applications continue from their previous state. For information on frame buffer size in vGPU profiles, refer to the NVIDIA Virtual GPU documentation.

The expected VM stun times and the estimated worst-case stun times are listed in the following tables. The expected stun times were tested over a 10Gb network with NVIDIA Tesla V100 PCIe 32 GB GPUs:

Table 97: Expected Stun Times for vMotion of vGPU VMs

Used vGPU Frame Buffer (GB)	VM Stun Time (sec)
1	2
2	4

Used vGPU Frame Buffer (GB)	VM Stun Time (sec)
4	6
8	12
16	22
32	39

Table 98: Estimated Worst-Case Stun Times (sec)

vGPU Memory	VM Memory 4 GB	VM Memory 8 GB	VM Memory 16 GB	VM Memory 32 GB
1 GB	5	6	8	12
2 GB	7	9	11	15
4 GB	13	14	16	21
8 GB	24	25	28	32
16 GB	47	48	50	54
32 GB	91	92	95	99

Note:
When you consider the expected and estimated worst-case stun times, keep in mind the following points:

- The configured vGPU profile represents an upper bound to the used vGPU frame buffer. In many use cases, the amount of vGPU frame buffer memory used by the VM at any given time is below the assigned vGPU memory in the profile.
- Both expected and estimated worst-case stun times are only valid when migrating a single virtual machine. If you are concurrently migrating multiple virtual machines, that is, for a vSphere manual remediation process, the stun times will have adverse effects.
- The above estimates assume sufficient CPU, memory, PCIe, and network capacity to achieve 10 Gbps migration throughput.

DRS supports initial placement of vGPU VMs running vSphere 6.7 Update 1 and later without load balancing support.

VMware vSphere vMotion is supported only with and between compatible NVIDIA GPU device models and NVIDIA GRID host driver versions as defined and supported by NVIDIA. For compatibility information, refer to the NVIDIA Virtual GPU User Guide.

To check compatibility between NVIDIA vGPU host drivers, vSphere, and Horizon, refer to the Broadcom Compatibility Guide.

How to Set a Stun Time Limit for Your vGPU Virtual Machines

Learn how to set a stun time limit per virtual machine when you migrate NVIDIA vGPU-powered virtual machines with vSphere vMotion. Setting a stun time limit might prevent vCenter from powering on the virtual machine or migrating it to a host and network whose estimated maximum stun time exceeds that limit.

- Verify that the vCenter instance is version 8.0 Update 2 or later.

- Verify that the source and destination ESX hosts are version 8.0 Update 2 or later.
- Verify that vMotion is enabled for vGPU virtual machines. The `vgpu.hotmigrate.enabled` advanced setting must be set to `true`. For more information about how to configure the vCenter advanced settings, see *Configure Advanced Settings* in the *vCenter Configuration* documentation.

Virtual machine stun time is the time when the virtual machine is inaccessible to users during vMotion. Starting with vSphere 8.0 Update 2, you can set a vMotion stun time limit for vGPU virtual machines.

The limit that you set must be higher than the estimated maximum stun time for the current device configuration. In case of multiple PCI devices, the stun time limit that you set must be higher than the sum of the contributions of all PCI devices. Setting a stun time limit that is lower than the estimated maximum stun time might prevent the virtual machine from powering on.

Note:
Maximum stun time estimates are only available for C-Series and Q-Series vGPU types.

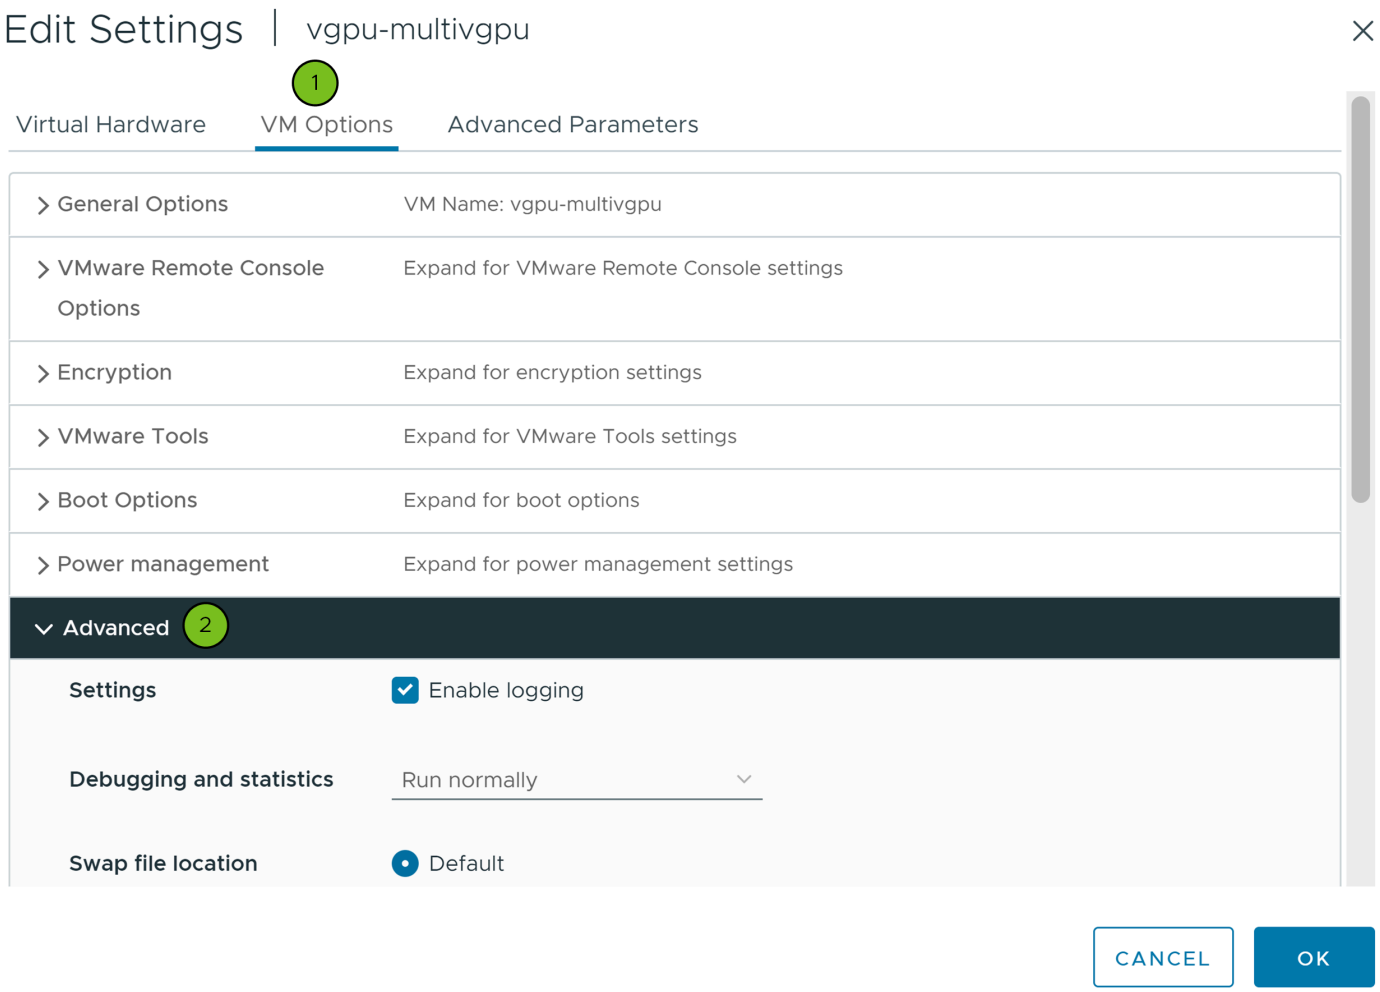
The maximum stun time is calculated on the basis of the bandwidth of the host on which the VM runs currently. The calculations might change at the time of migration if the destination host has lower bandwidth. For example, if a virtual machine is running on a host with a 25 Gbps vMotion NIC, but the destination host has a 10 Gbps vMotion NIC. At the time of migration the maximum stun time calculation is based on the 10 Gbps vMotion NIC.

Note:

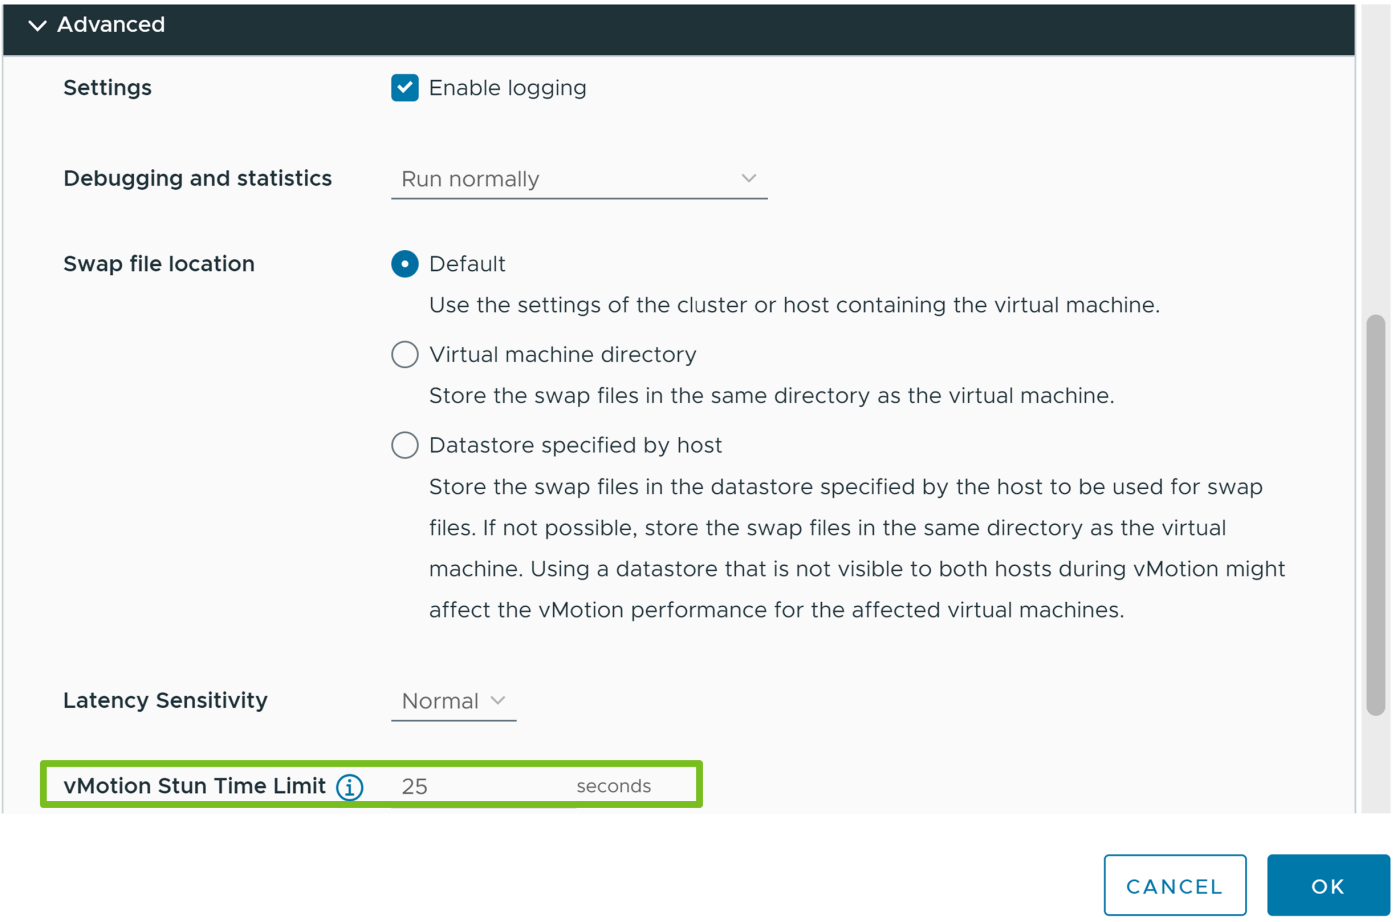
Starting with vSphere 8.0 Update 3, vMotion for vGPU virtual machines is activated by default. If you want to deactivate it, you must set the `vgpu.hotmigrate.enabled` advanced setting to `false`. For more information about how to configure the vCenter advanced settings, see *Configure Advanced Settings* in the *vCenter Configuration* documentation.

1. In the vSphere Client, click the main navigation menu

   (**),**
   and select **Inventory**.
2. Navigate to **Hosts and Clusters**.
3. Navigate to a vGPU virtual machine.
4. Right-click the virtual machine and select **Edit Settings**.
   The **Edit Settings** dialog box appears.
5. Click the **VM Options** tab and expand **Advanced**.



6. In the **vMotion Stun Time Limit** input field, enter the stun time limit in seconds.



If you set a stun time limit that is lower than the estimated maximum stun time for the PCI device configuration, a warning message appears. A warning message is also displayed on the **Virtual Hardware** tab.

7. Click **OK**.

Set a Stun Time Limit for a vMotion Migration of a Virtual Machine with a PCI Device

You can set a stun time limit per virtual machine when you migrate virtual machines with a PCI device with vSphere vMotion. Setting a stun time limit might prevent vCenter from powering on the virtual machine or migrating it to a host and network whose estimated maximum stun time exceeds that limit.

Verify that the vMotion network is configured through the Quickstart Workflow. For information about configuring the networking options for the vMotion traffic, see How to Add an ESX Host to Your vSphere Cluster by Using the Quickstart Workflow.

Virtual machine stun time is the time when the virtual machine is inaccessible to users during vMotion. You can set a vMotion stun time limit for the virtual machines with PCI devices. The limit that you set must be higher than the estimated maximum stun time for the current device configuration. If there are multiple PCI devices, the stun time limit that you set must be higher than the sum of the contributions of all PCI devices. Setting a stun time limit that is lower than the estimated maximum stun time might prevent the virtual machine from powering on.

For information on how to view the stun time for a PCI device, see View Stun Time Estimates During a vMotion Migration of a Virtual Machine with a PCI Device.

The maximum stun time is calculated based on the vMotion bandwidth of the host on which the virtual machine runs currently. If the destination host has lower bandwidth, the calculations might change at the time of migration. For example,

if a virtual machine is running on a host with a 25 Gbps vMotion NIC, but the destination host has a 10 Gbps vMotion NIC, at the time of migration the maximum stun time calculation is based on the 10 Gbps vMotion NIC.

Note:

You cannot set a stun time limit higher than 100 seconds.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Select **Hosts and Clusters**.
3. Navigate to the virtual machine with PCI device for which you want to set a stun time limit.
4. Right-click the virtual machine and select **Edit Settings**.

   The **Edit Settings** dialog box appears.
5. Click the **VM Options** tab and expand **Advanced**.
6. In the **vMotion Stun Time Limit** input field, enter the stun time limit in seconds.

   If you set a stun time limit that is lower than the estimated maximum stun time for the PCI device configuration, a warning message appears. A warning message is also displayed on the **Virtual Hardware** tab.
7. Click **OK**.

View Stun Time Estimates During a vMotion Migration of a Virtual Machine with a PCI Device

You can view the expected PCI device stun times during a migration of a virtual machine with vMotion and the estimated worst-case stun times.

Stun time is the time when the virtual machine is inaccessible to users during vMotion. During the stun time, you are unable to access the virtual machine, desktop, or application. After the migration is completed, access to the virtual machine resumes and all applications continue from their previous state.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Select **Hosts and Clusters**.
3. Navigate to the virtual machine with PCI device for which you want to view the stun time limit.
4. Right-click the virtual machine and select **Edit Settings**.

   The **Edit Settings** dialog box appears.
5. Click the **Virtual Hardware** tab, and expand the menu next to the PCI device for which you want to view the estimated stun times.
6. Next to **Estimated Max Stun Time**, you can see the estimated maximum stun time for the PCI device.
7. If you want to view the estimated stun times depending on the different bandwidth, click **View Reference Table**.

   When you consider the expected and estimated worst-case stun times, keep in mind the following points:

   - The estimated stun times are only valid when migrating a single virtual machine. If you are concurrently migrating multiple virtual machines, that is, for a vSphere manual remediation process, the stun times differ.
   - The estimates assume sufficient CPU, memory, PCIe, and network capacity to achieve 10-Gbps migration throughput.

Virtual Machines Swap File Location and vSphere vMotion Compatibility

Virtual machine swap file location affects vMotion compatibility in different ways depending on the version of ESX running on the virtual machine's host.

You can configure ESX 7.0 or later hosts to store virtual machine swap files with the virtual machine configuration file, or on a local swap file datastore specified for that host.

The location of the virtual machine swap file affects vMotion compatibility as follows:

- For migrations between hosts running ESX 7.0 and later, vMotion and migrations of suspended and powered-off virtual machines are allowed.
- During a migration with vMotion, if the swap file location on the destination host differs from the swap file location on the source host, the swap file is copied to the new location. This activity can result in slower migrations with vMotion. If the destination host cannot access the specified swap file location, it stores the swap file with the virtual machine configuration file.

For information about using swap files, see Using Swap Files with vSphere in the *vSphere Resource Management* documentation.

vSphere vMotion Notifications for Latency Sensitive Applications

Starting with vSphere 8.0, you can notify an application running inside the guest OS of a virtual machine when a vSphere vMotion event starts and finishes. This notification mechanism allows latency sensitive applications to prepare or delay a vSphere vMotion operation.

In cases of latency sensitive applications, such as VoIP applications and high frequency trading applications, vSphere vMotion and vSphere DRS are usually deactivated. vSphere 8.0 introduces a notification mechanism which allows you to notify an application that a vSphere vMotion is about to happen so that the application takes the necessary steps to prepare. vSphere vMotion pauses after generating the start event and waits for the application to acknowledge the start notification before it proceeds.

> **Note:**
>
> Enabling the notification mechanism for vSphere vMotion operations might result in an increase of the overall vSphere vMotion time.

How to Configure a Virtual Machine for vSphere vMotion Notifications

By default, the notification mechanism is deactivated. To enable the notification mechanism on a virtual machine, the virtual machine must be of hardware version 20 or above and you must configure the following advanced virtual machine configuration options.

You can use vSphere Web Services API to enable sending notifications to applications running inside the virtual machine, and to specify the maximum period of time in seconds that an application has to prepare for the vMotion operation.

- To enable sending notifications to applications running inside the virtual machine, set the `vmx.vmOpNotificationToApp.enabled` virtual machine property to `true`
- To specify the maximum period of time in seconds that an application has to prepare for the vMotion operation, use the `vmx.vmOpNotificationToApp.timeout` virtual machine property. When a vSphere vMotion operation generates a start event, the vMotion operation pauses and waits for an acknowledgment from the application to proceed. vSphere vMotion waits for the notification timeout that you specify.

  This property is optional and is not set by default. You can use it to configure a more restrictive timeout for a specific virtual machine. If left unset, the host notification configuration is used.

For more information, see the virtual machine data object properties in the vSphere Web Services API documentation. For information on how to use the vSphere Web Services SDK, see the vSphere Management SDK guide.

How to Configure a Host for vSphere vMotion Notifications

You can use the `VmOpNotificationToApp.Timeout` advanced host configuration setting, to specify a notification timeout that applies to all virtual machines on a host. Use the `ConfigManager` APIs to set a value to this configuration

property. The default notification timeout is `0`. In this case, application notifications are generated but the vSphere vMotion operations are not delayed.

If you set a notification timeout on a host and a virtual machine running on the host at the same time, the smaller value is used.

For information on how to use the vSphere Web Services SDK, see the vSphere Management SDK guide.

How to Register an Application for vSphere vMotion Notifications

To enable an application to receive notifications for vSphere vMotion events, you must have VMware Tools installed on the virtual machine hosting the application. For more information about installing and configuring VMware Tools, see the *VMware Tools* documentation.

With vSphere 8.0, you can register only one application per virtual machine. An application that wants to receive vSphere vMotion notifications, can use the following guest RPC calls and check for new vMotion events periodically, for example, every 1 or 2 seconds, using the `vm-operation-notification.check-for-event` guest RPC call.

For information on how to use guest RPC calls, see the vSphere Guest SDK guide.

Command	Description
`vm-operation-notification.register`	Registers an application to start receiving notifications for vSphere vMotion events.
`vm-operation-notification.unregister`	Unregisters an application from receiving notifications for vSphere vMotion events.
`vm-operation-notification.list`	Retrieves information about the registered application running on a virtual machine on the host.
`vm-operation-notification.check-for-event`	Retrieves information about the vSphere vMotion event registered at the time of the call.
`vm-operation-notification.ack-event`	Acknowledges a vSphere vMotion start event.

How to Migrate Your Virtual Machine to a New Compute Resource

Learn how to use vSphere vMotion and the **Migration** wizard to migrate a powered-on virtual machine from one compute resource to another. To relocate only the disks of a powered-on virtual machine, migrate the virtual machine to a new datastore by using Storage vMotion.

Verify that your hosts and virtual machines meet the requirements for migration with vMotion with shared storage.

- Verify that your hosts and virtual machines meet the requirements for migration with vMotion. See Host Configuration for vSphere vMotion and Virtual Machine Conditions and Limitations for vSphere vMotion.
- Verify that the storage that contains the virtual machine disks is shared between the source and target hosts. See vSphere vMotion Shared Storage Requirements.
- For migration across vCenter instances, verify whether your system meets additional requirements. See What Are the Requirements for vMotion Between vCenter Instances.
- For migration of a virtual machine with NVIDIA vGPU, verify that the target ESX host has a free vGPU slot. Also, verify that the `vgpu.hotmigrate.enabled` advanced setting is set to `true`. For more information about configuring vCenter advanced settings, see *Configure Advanced Settings* in the *vCenter Configuration* documentation.
- Required privilege: **Resource** > **Migrate powered on virtual machine**

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Select **Hosts and Clusters**, and navigate to the virtual machine.
3. Right-click the virtual machine and select **Migrate**.
   a) To locate a virtual machine, select a data center, folder, cluster, resource pool, host, or vApp.
   b) Click the **Virtual Machines** tab.
4. Click **Change compute resource only** and click **Next**.
5. Select a host, cluster, resource pool, or vApp to run the virtual machine, and click **Next**.
   Any compatibility problem appears in the Compatibility panel. Fix the problem, or select another host or cluster.

   Possible targets include hosts and fully automated DRS clusters in the same or another vCenter system. If your target is a non-automated cluster, select a host within the non-automated cluster.

   Important:

   If the virtual machine that you migrate has an NVDIMM device and virtual PMem hard disks, the destination host or cluster must have available PMem resources. Otherwise, the compatibility check fails and you cannot proceed further with the migration.

   If the virtual machine that you migrate does not have an NVDIMM device, but it has virtual PMem hard disks, the destination host or cluster must have available PMem resources, so that all PMem hard disks remain stored on a PMem datastore. Otherwise, all the hard disks use the storage policy and datastore selected for the configuration files of the virtual machine.

   Important:
   Migrating a virtual machine that has an NVDIMM device or a vPMem disk to a host that does not have the proper license fails and leaves the virtual machine in an unmanageable state for 90 seconds. You can afterwards retry the migration and select a destination host that is licensed to use PMem devices.
6. Select a destination network for all VM network adapters connected to a valid source network and click **Next**.

   You can click **Advanced** to select a new destination network for each VM network adapter connected to a valid source network.

   You can migrate a virtual machine network to another distributed switch in the same or to another data center or vCenter.
7. Select the migration priority level and click **Next**.

Option	Description
Schedule vMotion with high priority	vCenter attempts to reserve resources on both the source and destination hosts to be shared among all concurrent migrations with vMotion. vCenter grants a larger share of host CPU resources. If sufficient CPU resources are not immediately available, vMotion is not initiated.
Schedule normal vMotion	vCenter reserves resources on both the source and destination hosts to be shared among all concurrent migrations with vMotion. vCenter grants a smaller share of host CPU resources. If there is a lack of CPU resources, the duration of vMotion can be extended.

8. Review the page and click **Finish**.

vCenter moves the virtual machine to the new host or storage location.

Event messages appear in the **Events** tab. The data displayed on the **Summary** tab shows the status and state throughout the migration. If errors occur during migration, the virtual machines revert to their original states and locations.

What is Migration with Storage vMotion

With Storage vMotion, you can migrate a virtual machine and its disk files from one datastore to another while the virtual machine is running. You can also move virtual machines off of arrays for maintenance or to upgrade.

With Storage vMotion you also have the flexibility to optimize disks for performance, or to transform disk types, which you can use to reclaim space.

You can choose to place the virtual machine and all its disks in a single location, or you can select separate locations for the virtual machine configuration file and each virtual disk. The virtual machine does not change execution host during a migration with Storage vMotion.

During a migration with Storage vMotion, you can change the disk provisioning type.

Migration with Storage vMotion changes virtual machine files on the destination datastore to match the inventory name of the virtual machine. The migration renames all virtual disk, configuration, snapshot, and `.nvram` files. If the new names exceed the maximum filename length, the migration does not succeed.

Storage vMotion has several uses in administering virtual infrastructure, including the following examples of use.

- Storage maintenance and reconfiguration. You can use Storage vMotion to move virtual machines off a storage device to allow maintenance or reconfiguration of the storage device without virtual machine downtime.
- Redistributing storage load. You can use Storage vMotion to redistribute virtual machines or virtual disks to different storage volumes to balance capacity or improve performance.

Storage vMotion Requirements and Limitations

A virtual machine and its host must meet resource and configuration requirements for the virtual machine disks to be migrated with Storage vMotion.

Storage vMotion is subject to the following requirements and limitations:

- Virtual machine disks must be in persistent mode or be raw device mappings (RDMs). For virtual compatibility mode RDMs, you can migrate the mapping file or convert to thick-provisioned or thin-provisioned disks during migration if the destination is not an NFS datastore. If you convert the mapping file, a new virtual disk is created and the contents of the mapped LUN are copied to this disk. For physical compatibility mode RDMs, you can migrate the mapping file only.
- Migration of virtual machines during VMware Tools installation is not supported.
- Because VMFS3 datastores do not support large capacity virtual disks, you cannot move virtual disks greater than 2 TB from a VMFS5 datastore to a VMFS3 datastore.
- ESX 4.0 and later hosts do not require vMotion configuration to perform migration with Storage vMotion.
- The host on which the virtual machine is running must have access to both the source and target datastores.
- For limits on the number of simultaneous migrations with vMotion and Storage vMotion, see vCenter Limits on Simultaneous Migrations.

How to Migrate Your Virtual Machine with Storage vMotion

Learn how to use Storage vMotion to migrate the configuration file of a virtual machine and its virtual disks to a new storage. You can migrate the virtual machine while it is powered on.

- Verify that your system satisfies the requirements for Storage vMotion. See Storage vMotion Requirements and Limitations.
- For migration of a virtual machine with NVIDIA vGPU, verify that the ESX host on which the virtual machine runs has a free vGPU slot when the host is with version 7.0 Update 2 and earlier. Starting with vSphere 7.0 Update 3, the source hosts are not required to have a free vGPU slot.
- Verify that the `vgpu.hotmigrate.enabled` advanced setting is set to `true`. For more information about configuring vCenter advanced settings, see Configure Advanced Settings in the *vCenter Configuration* documentation.
- Required privilege: **Resource** > **Migrate powered on virtual machine**

1. In the vSphere Client, click the main navigation menu

   ( ),

   and select **Inventory**.
2. Select **Hosts and Clusters**, and navigate to the virtual machine.
3. Right-click the virtual machine and select **Migrate**.
   a) To locate a virtual machine, select a data center, folder, cluster, resource pool, host, or vApp.
   b) Click the **Virtual Machines** tab.
4. Click **Change storage only** and click **Next**.
5. Select the format for the virtual machine's disks.

Option	Action
Same format as source	Use the same format as the source virtual machine.
Thick Provision Lazy Zeroed	Create a virtual disk in a default thick format. Space required for the virtual disk is allocated during creation. Any data remaining on the physical device is not erased during creation. Instead, it is zeroed out on demand on first write from the virtual machine.
Thick Provision Eager Zeroed	Create a thick disk that supports clustering features such as Fault Tolerance. Space required for the virtual disk is allocated at creation time. In contrast to the thick provision lazy zeroed format, the data remaining on the physical device is zeroed out during creation. It might take longer to create disks in this format than to create other types of disks.
Thin Provision	Use the thin provisioned format. At first, a thin provisioned disk uses only as much datastore space as the disk initially needs. If the thin disk needs more space later, it can expand to the maximum capacity allocated to it.

6. Select a virtual machine storage policy from the **VM Storage Policy** drop-down menu.

   Storage policies specify storage requirements for applications that run on the virtual machine.

   Important:

   If the virtual machine hard disks use different storage policies, the new policy that you select only applies to non-PMem hard disks. PMem hard disks are migrated to the host-local PMem datastore of the destination host.
7. Select the datastore location where you want to store the virtual machine files.

Option	Action
Store all virtual machine files in the same location on a datastore.	Select a datastore and click **Next**.
Store all virtual machine files in the same Storage DRS cluster.	1. Select a Storage DRS cluster. 2. To deactivate Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 3. Click **Next**.
Store virtual machine configuration files and disks in separate locations.	1. Click **Advanced**. **Note:** You can use the **Advanced** option to downgrade from or upgrade to PMem storage. 2. For the virtual machine configuration file and for each virtual disk, select **Browse**, and select a datastore or Storage DRS cluster.

Option	Action
	Note: Configuration files cannot be stored on a PMem datastore. 3. If you selected a Storage DRS cluster and do not want to use Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 4. Click **Next**.

8. On the Ready to complete page, review the details and click **Finish**.

vCenter moves the virtual machine to the new storage location. Names of migrated virtual machine files on the destination datastore match the inventory name of the virtual machine.

Event messages appear in the **Events** tab. The data displayed on the **Summary** tab shows the status and state throughout the migration. If errors occur during migration, the virtual machines revert to their original states and locations.

How to Migrate Your Virtual Machine to a New Compute Resource and Storage

Learn how to move a virtual machine from your vSphere inventory to another compute resource and move its disks or virtual machine folder to another datastore. With vMotion, you can migrate a virtual machine and its disks and files while the virtual machine is powered on.

- Verify that your hosts and virtual machines meet the requirements for live migration. See Requirements and Limitations for vMotion Without Shared Storage.
- For migration across vCenter instances, verify whether your system meets additional requirements. See What Are the Requirements for vMotion Between vCenter Instances.
- For migration of a virtual machine with NVIDIA vGPU, verify that the target ESX host has a free vGPU slot. Also, verify that the `vgpu.hotmigrate.enabled` advanced setting is set to `true`. For more information about configuring vCenter advanced settings, see Configure Advanced Settings in *vCenter Configuration*.
- Required privilege: **Resource** > **Migrate powered on virtual machine**

Simultaneous migration to a new compute resource and datastore provides greater mobility for virtual machines by eliminating the vCenter boundary. Virtual machine disks or contents of the virtual machine folder are transferred over the vMotion network to reach the destination host and datastores.

To make disk format changes and preserve them, you must select a different datastore for the virtual machine files and disks. You cannot select the same datastore on which the virtual machine disks currently reside.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Select **Hosts and Clusters**, and navigate to the virtual machine.
3. Right-click the virtual machine and select **Migrate**.
   a) To locate a virtual machine, select a data center, folder, cluster, resource pool, host, or vApp.
   b) Click the **Virtual Machines** tab.
4. Select **Change both compute resource and storage** and click **Next**.
5. Select a destination resource for the virtual machine, and click **Next**.

   Any compatibility problems appear in the Compatibility panel. Fix the problem, or select another host or cluster.

   Possible targets include hosts and fully automated DRS clusters. If your target is a non-automated cluster, select a host within the non-automated cluster.

If your environment has more than one vCenter instances, you can move virtual machines from one vCenter inventory to another.

Important:

If the virtual machine that you migrate has an NVDIMM device and uses PMem storage, the destination host or cluster must have available PMem resources. Otherwise, the compatibility check fails and you cannot proceed further with the migration.

If the virtual machine that you migrate does not have an NVDIMM device but it uses PMem storage, you must select a host or cluster with available PMem resources, so that all PMem hard disks remain stored on a PMem datastore. Otherwise, all the hard disks use the storage policy and datastore selected for the configuration files of the virtual machine.

Important:

Migrating a virtual machine that has an NVDIMM device or a vPMem disk to a host that does not have the proper license fails and leaves the virtual machine in an unmanageable state for 90 seconds. You can afterwards retry the migration and select a destination host that is licensed to use PMem devices.

6. Select the format for the virtual machine's disks.

Option	Action
Same format as source	Use the same format as the source virtual machine.
Thick Provision Lazy Zeroed	Create a virtual disk in a default thick format. Space required for the virtual disk is allocated during creation. Any data remaining on the physical device is not erased during creation. Instead, it is zeroed out on demand on first write from the virtual machine.
Thick Provision Eager Zeroed	Create a thick disk that supports clustering features such as Fault Tolerance. Space required for the virtual disk is allocated at creation time. In contrast to the thick provision lazy zeroed format, the data remaining on the physical device is zeroed out during creation. It might take longer to create disks in this format than to create other types of disks.
Thin Provision	Use the thin provisioned format. At first, a thin provisioned disk uses only as much datastore space as the disk initially needs. If the thin disk needs more space later, it can expand to the maximum capacity allocated to it.

7. Select a virtual machine storage policy from the **VM Storage Policy** drop-down menu.

   Storage policies specify storage requirements for applications that run on the virtual machine.

   Important:

   If the virtual machine hard disks use different storage policies, the new policy that you select only applies to non-PMem hard disks. PMem hard disks are migrated to the host-local PMem datastore of the destination host.

8. Select the datastore location where you want to store the virtual machine files.

Option	Action
Store all virtual machine files in the same location on a datastore.	Select a datastore and click **Next**.
Store all virtual machine files in the same Storage DRS cluster.	1. Select a Storage DRS cluster. 2. To deactivate Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 3. Click **Next**.
Store virtual machine configuration files and disks in separate locations.	1. Click **Advanced**.

Option	Action
	Note: You can use the **Advanced** option to downgrade from or upgrade to PMem storage. 2. For the virtual machine configuration file and for each virtual disk, select **Browse**, and select a datastore or Storage DRS cluster. **Note:** Configuration files cannot be stored on a PMem datastore. 3. If you selected a Storage DRS cluster and do not want to use Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 4. Click **Next**.

9. Select a destination network for all VM network adapters connected to a valid source network and click **Next**.

   You can click **Advanced** to select a new destination network for each VM network adapter connected to a valid source network.

   You can migrate a virtual machine network to another distributed switch in the same or to another data center or vCenter.

10. Select the migration priority level and click **Next**.

Option	Description
Schedule vMotion with high priority	vCenter attempts to reserve resources on both the source and destination hosts to be shared among all concurrent migrations with vMotion. vCenter grants a larger share of host CPU resources. If sufficient CPU resources are not immediately available, vMotion is not initiated.
Schedule normal vMotion	vCenter reserves resources on both the source and destination hosts to be shared among all concurrent migrations with vMotion. vCenter grants a smaller share of host CPU resources. If there is a lack of CPU resources, the duration of vMotion can be extended.

11. On the Ready to complete page, review the details and click **Finish**.

vCenter moves the virtual machine to the new host or storage location.

Event messages appear in the **Events** tab. The data displayed on the **Summary** tab shows the status and state throughout the migration. If errors occur during migration, the virtual machines revert to their original states and locations.

vSphere vMotion in Environments Without Shared Storage

You can use vSphere vMotion to migrate virtual machines to a different compute resource and storage simultaneously. Unlike vSphere Storage vMotion, which requires a single host to have access to both the source and destination datastore, you can migrate virtual machines across storage accessibility boundaries.

vSphere vMotion does not require environments with shared storage. This is useful for performing cross-cluster migrations, when the target cluster machines might not have access to the storage of the source cluster. Processes that are working on the virtual machine continue to run during the migration with vSphere vMotion.

You can use vSphere vMotion to migrate virtual machines across vCenter instances.

You can place the virtual machine and all its disks in a single location or select separate locations for the virtual machine configuration file and each virtual disk. In addition, you can change virtual disks from thick-provisioned to thin-provisioned or from thin-provisioned to thick-provisioned. For virtual compatibility mode RDMs, you can migrate the mapping file or convert from RDM to VMDK.

vSphere vMotion without shared storage is useful for virtual infrastructure administration tasks similar to vSphere vMotion with shared storage or vSphere Storage vMotion tasks.

- Host maintenance. You can move virtual machines from a host to allow maintenance of the host.
- Storage maintenance and reconfiguration. You can move virtual machines from a storage device to allow maintenance or reconfiguration of the storage device without virtual machine downtime.
- Storage load redistribution. You can manually redistribute virtual machines or virtual disks to different storage volumes to balance capacity or improve performance.

Requirements and Limitations for vMotion Without Shared Storage

If you want to migrate a virtual machine with vMotion in the absence of shared storage, the virtual machine and its host must meet resource and configuration requirements for the virtual machine files and disks.

vMotion in an environment without shared storage is subject to the following requirements and limitations:

- The hosts must meet the networking requirement for vMotion. See What Are the vSphere vMotion Networking Requirements.
- The virtual machines must be properly configured for vMotion. See Virtual Machine Conditions and Limitations for vSphere vMotion.
- Virtual machine disks must be in persistent mode or be raw device mappings (RDMs). See Storage vMotion Requirements and Limitations.
- The destination host must have access to the destination storage.
- When you move a virtual machine with RDMs and do not convert those RDMs to VMDKs, the destination host must have access to the RDM LUNs.
- Consider the limits for simultaneous migrations when you perform a vMotion migration without shared storage. This type of vMotion counts against the limits for both vMotion and Storage vMotion, so it consumes both a network resource and 16 datastore resources. See vCenter Limits on Simultaneous Migrations.

When you migrate a powered-on virtual machine with vMotion in the absence of shared storage, the migration goes over the network using the vMotion vmknic, and the data is transferred directly between the two ESX hosts.

Migrating Virtual Machines Between vCenter Systems

You can migrate powered-on and powered-off virtual machines between vCenter instances. With Advanced Cross vCenter vMotion, you can also move or clone workloads across vCenter systems both between on-premises environments and between cloud and on-premises environments.

Cold and Hot migration of virtual machines across vCenter systems is helpful in certain VM provisioning cases.

- Balance workloads across clusters and vCenter instances.
- Elastically expand or shrink capacity across resources in different vCenter instances in the same site or in another geographical area.
- Move virtual machines between environments that have different purposes, for example, from a development to production.
- Move virtual machines to meet different Service Level Agreements (SLAs) regarding storage space, performance, and so on.

> **Note:**
> During the migration of a virtual machine to another vCenter system, the performance data that has been collected about the virtual machine is lost.

What Are the Requirements for vMotion Between vCenter Instances

You can use vSphere vMotion across vCenter instances if your system meets certain requirements.

The following list sums the requirements that your system must meet so that you can use migration across vCenter instances:

- When you migrate virtual machines across vCenter instances without using Advanced Cross vCenter vMotion, verify that you meet the following requirements.
  - Both vCenter instances must be in the same vCenter Single Sign-On domain.
  - The source and destination vCenter instances and ESX hosts must be 6.7 or later.
  - Both vCenter instances must be time-synchronized with each other for correct vCenter Single Sign-On token verification.
  - For migration of compute resources only, both vCenter instances must be connected to the shared virtual machine storage.
- When you migrate virtual machines across vCenter instances in different vCenter Single Sign-On domains with Advanced Cross vCenter vMotion, verify that you meet the following requirements.
  - The vCenter instance from which you initiate the import or export of virtual machines must be version 7.0 Update 1c or later.

Network Compatibility Checks During vMotion Between vCenter Instances

Migration of virtual machines between vCenter instances moves virtual machines to new networks. The migration process performs checks to verify that the source and destination networks are similar.

vCenter performs network compatibility checks to prevent the following configuration problems:

- vMotion between distributed switches of different versions
- vMotion from an external network to an internal network
- vMotion to a distributed switch that is not working properly

vCenter does not perform checks for and notify you about the following problems:

- If the source and destination distributed switches are not in the same broadcast domain, virtual machines lose network connectivity after migration.
- If the source and destination distributed switches do not have the same services configured, virtual machines might lose network connectivity after migration.

MAC Address Management During Migration Between vCenter Systems

When you move a virtual machine between vCenter instances, the environment specifically handles MAC address migration to avoid address duplication and loss of data in the network.

In an environment with multiple vCenter instances, when a virtual machine is migrated, its MAC addresses are transferred to the target vCenter. The source vCenter adds the MAC addresses to a denylist so that it does not assign them to newly created virtual machines.

To reclaim unused MAC addresses from the denylist, contact VMware Technical Support for assistance.

Export or Clone a Virtual Machine with Advanced Cross vCenter vMotion

Learn how to export or clone workloads to a target vCenter system by using Advanced Cross vCenter vMotion. You can initiate migration of workloads both from on-premise environments and from cloud environments.

- Obtain the credentials for the administrator accounts of the vCenter instances to which you want to migrate virtual machines.
- Verify that the target vCenter instances to which you export or clone virtual machines are version 6.7 or later.
- Verify that the source vCenter instance from which you export virtual machines is version 7.0 Update 1c or later if you want to export virtual machines to other vCenter instances.
- Verify that the source vCenter instance from which you clone virtual machines is version 7.0 Update 3 or later.
- Verify that the destination ESX hosts are version 6.7 or later.
- If the virtual machine that you migrate has an NVDIMM device and uses PMem storage, verify that the destination host or cluster have available PMem resources.
- If you migrate a virtual machine that has an NVDIMM device or a vPMem disk, verify that the destination host has the proper license.

- Required privilege: **Resource.Query vMotion**
- When you migrate powered on virtual machines, verify that you meet the following requirements.
  - Required privilege: **Resource.Migrate powered on virtual machine**
  - Verify that your hosts and virtual machines meet the requirements for migration with vMotion. See Host Configuration for vSphere vMotion and Virtual Machine Conditions and Limitations for vSphere vMotion.
  - Verify that your hosts and virtual machines meet the requirements for live migration. See Requirements and Limitations for vMotion Without Shared Storage.
- When you migrate powered off virtual machines, verify that you meet the following requirements.
  - Required privilege: **Resource.Migrate powered off virtual machine**
  - Make sure that you are familiar with the requirements for cold migration. See Cold Migration in Your vSphere Environment.
- Required ports:
  - Port 8000 on the ESX host for vMotion.
  - Port 902 on the ESX host for NFC.
  - Port 443 between the two vCenter instances.

  For the list of all supported ports and protocols in VMware products, see the VMware Ports and Protocols Tool™ at https://ports.broadcom.com/view.

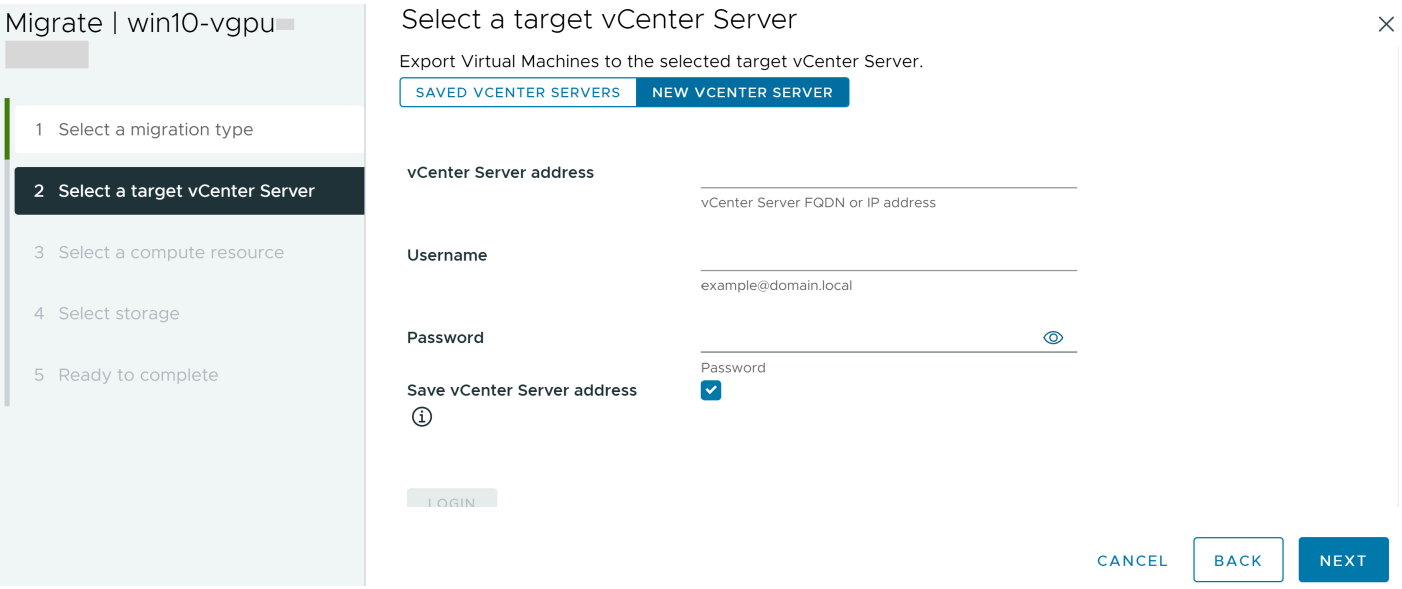
Advanced Cross vCenter vMotion does not depend on vCenter linking and you can migrate virtual machines across vCenter systems in different vCenter Single Sign-On domains. For example, when you deploy a new vCenter instance, you can migrate virtual machines from the earlier version of your vCenter instance to the newly provisioned one.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Navigate to**Hosts and Clusters**.
3. From the inventory tree, select the host or cluster that contains the virtual machines you want to migrate.
4. On the **VMs** tab, click the **Virtual Machines** button.
5. From the virtual machines list, select the virtual machines that you want to migrate.
6. Right-click the selection and click **Migrate**.
7. If a confirmation dialog box appears, click **Yes**.

   The migration wizard appears.
8. Select **Cross vCenter export** as the migration type.
   a) Optional: To create a clone of the virtual machine on the target vCenter, select the **Keep VMs on the source vCenter Server (performs a VM clone operation).** check box.
   b) Click **Next** to continue.
9. Select the target vCenter instance to which you want to export or clone virtual machines.



Option	Action
Saved vCenter Instances	From the drop-down menu, select the IP address or FQDN of a saved vCenter.
New vCenter Instance	1. Enter the IP address or FQDN, user name, and password of a vCenter instance. **Note:** The check box **Save vCenter address** is selected by default. If you do not want to save the vCenter address, deselect the check box. 2. Click **Login**.

The connection to a saved vCenter instance is valid only for the current user session. You must enter the credentials of the target vCenter instances for each login session.

10. If a **Security Alert** dialog box appears, click **Yes**.
11. Click **Next** to continue.
12. Select the destination compute resource for this virtual machine migration and click **Next**.

    Possible targets include hosts and DRS clusters with any level of automation. If DRS is not enabled for a cluster, select a specific host in the cluster rather than selecting the cluster.

    Important:

    If the virtual machine that you migrate does not have an NVDIMM device but it uses PMem storage, you must select a host or cluster with available PMem resources, so that all PMem hard disks remain stored on a PMem datastore. Otherwise, all the hard disks use the storage policy and datastore selected for the configuration files of the virtual machine.

    Important:
    When you try to migrate a virtual machine that has an NVDIMM device or a vPMem disk to a host that does not have the proper license, the operation fails and the virtual machine is in an unmanageable state for 90 seconds. After 90 seconds, you can retry the migration, and select a destination host that is licensed to use PMem devices.

13. If a compatibility problem appears in the Compatibility pane, fix the problem or select another host or cluster for the migration.
14. Select the destination storage for the virtual machine migration.
    a) Select the storage type for the virtual machine configuration files and all the hard disks.

Mode	Description
Standard	All virtual disks are stored on a standard datastore.
PMem	All virtual disks are stored on the local PMem datastore of the host. Configuration files cannot be stored on a PMem datastore. You must additionally select a regular datastore for the configuration files of the virtual machine.
Hybrid	All PMem virtual disks remain stored on a PMem datastore. Your choice of a VM storage policy and your choice of a datastore affects non-PMem disks.

    You can select the type of storage only if PMem or Hybrid storage types are available in the data center.
    b) Select the format for the virtual machine's disks.

Option	Action
Same format as source	Use the same format as the source virtual machine.
Thick Provision Lazy Zeroed	Create a virtual disk in a default thick format. Space required for the virtual disk is allocated during creation. Any data remaining on the physical device is not erased during creation. Instead, it is zeroed out on demand on first write from the virtual machine.
Thick Provision Eager Zeroed	Create a thick disk that supports clustering features such as Fault Tolerance. Space required for the virtual disk is allocated at creation time. In contrast to the thick provision lazy zeroed format, the data remaining on the physical device is zeroed out during creation. It might take longer to create disks in this format than to create other types of disks.
Thin Provision	Use the thin provisioned format. At first, a thin provisioned disk uses only as much datastore space as the disk initially needs. If the thin disk needs more space later, it can expand to the maximum capacity allocated to it.

    c) Select a virtual machine storage policy from the **VM Storage Policy** drop-down menu.

    Storage policies specify storage requirements for applications that run on the virtual machine. You can also select the default policy for vSAN or Virtual Volumes datastores.

    Important:
    If the virtual machine hard disks use different storage policies, the new policy that you select only applies to non-PMem hard disks. PMem hard disks are migrated to the host-local PMem datastore of the destination host.
    d) Select the datastore location for the virtual machine files.

Option	Action
Store all virtual machine files in the same location on a datastore.	Select a datastore from the list and click **Next**.
Store all virtual machine files in the same Storage DRS cluster.	1. Select a Storage DRS cluster. 2. If you want to migrate the virtual machine to a Storage DRS cluster and do not want to use Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 3. Click **Next**.

Option	Action
Store virtual machine configuration files and disks in separate locations.	1. Click **Configure per disk**. **Note:** You can use the **Configure per disk** option to downgrade from or upgrade to PMem storage. 2. For the virtual machine configuration file and for each virtual disk, select **Browse**, and select a datastore or a Storage DRS cluster. **Note:** Configuration files cannot be stored on a PMem datastore. 3. If you want to migrate the virtual machine to a Storage DRS cluster and do not want to use Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 4. Click **Next**.

15. If a compatibility problem appears in the Compatibility pane, fix the problem or select another destination storage for the migration.
16. Select the destination folder for the virtual machine migration and click **Next**.
17. Select the destination networks for the virtual machine migration.

Option	Action
Select a destination network for all VM network adapters connected to a valid source network.	1. Click the arrow in the **Destination Network** column and select **Browse**. 2. Select a destination network and click **OK**. 3. Click **Next**.
Select a different destination network for each VM network adapter connected to a valid source network.	1. Click **Advanced**. 2. Click the arrow in the **Destination Network** column and select **Browse**. 3. Select a destination network and click **OK**. 4. Click **Next**.

18. On the **Ready to complete** page, review the details and click **Finish**.

The virtual machines are moved or cloned to the destination folder in the new vCenter instance. You can monitor the migration process in the **Recent tasks** pane. If errors occur during the migration, the virtual machines revert to their original states and locations.

Import or Clone a Virtual Machine with Advanced Cross vCenter vMotion

Learn how to use Advanced Cross vCenter vMotion to import or clone workloads from a source vCenter system. You can initiate migration of workloads both from on-premise environments and from cloud environments.

- Obtain the credentials for the administrator account of the vCenter instance from which you want to import or clone virtual machines.
- Verify that the source vCenter instances from which you import or clone virtual machines are version 6.7 or later.
- Verify that the target vCenter instance to which you import virtual machines is version 7.0 Update 1c or later.
- Verify that the target vCenter instance to which you clone virtual machines is version 7.0 Update 1c or later.
- Verify that the destination ESX hosts are version 6.7 or later.
- If the virtual machine that you migrate has an NVDIMM device and uses PMem storage, verify that the destination host or cluster have available PMem resources.
- If you migrate a virtual machine that has an NVDIMM device or a vPMem disk, verify that the destination host has the proper license.
- Required privilege: **Resource.Query vMotion**

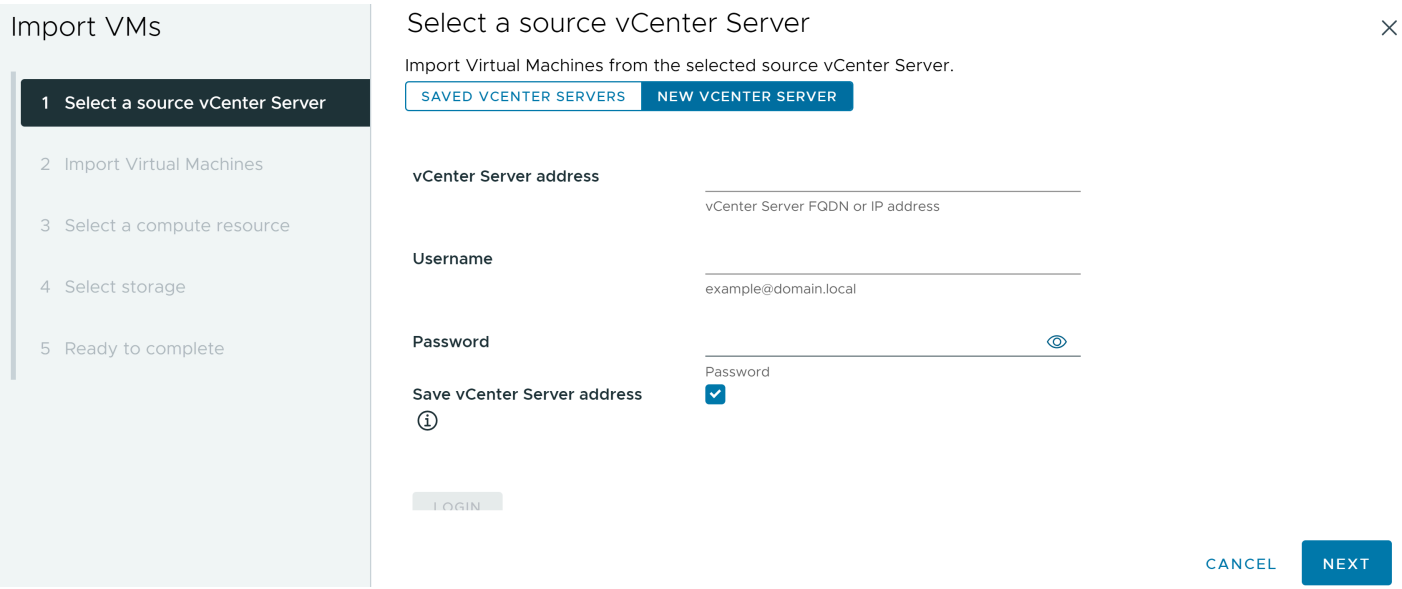
- When you migrate powered on virtual machines, verify that you meet the following requirements.
  - Required privilege: **Resource.Migrate powered on virtual machine**
  - Verify that your hosts and virtual machines meet the requirements for migration with vMotion. See Host Configuration for vSphere vMotion and Virtual Machine Conditions and Limitations for vSphere vMotion.
  - Verify that your hosts and virtual machines meet the requirements for live migration. See Requirements and Limitations for vMotion Without Shared Storage.
- When you migrate powered off virtual machines, verify that you meet the following requirements.
  - Required privilege: **Resource.Migrate powered off virtual machine**
  - Make sure that you are familiar with the requirements for cold migration. See Cold Migration in Your vSphere Environment.
- Required ports:
  - Port 8000 on the ESX host for vMotion.
  - Port 902 on the ESX host for NFC.
  - Port 443 between the two vCenter instances.

  For the list of all supported ports and protocols in VMware products, see the VMware Ports and Protocols Tool™ at https://ports.broadcom.com/.

Advanced Cross vCenter vMotion does not depend on vCenter linking and you can migrate virtual machines across vCenter systems in different vCenter Single Sign-On domains. For example, when you deploy a new vCenter instance, you can migrate virtual machines from the earlier version of your vCenter instance to the newly provisioned one.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Select **Hosts and Clusters**.
3. From the inventory tree, right-click the host or cluster to which you want to import virtual machines.
4. Click **Import VMs**.

   The **Import VMs** wizard appears.
5. Select the source vCenter instance from which you want to import virtual machines.



Option	Action
Saved vCenter Instances	From the drop-down menu, select the IP address or FQDN of a saved vCenter instance.

Option	Action
New vCenter Instance	1. Enter the IP address or FQDN, user name, and password of a vCenter instance. **Note:** The check box **Save vCenter Server address** is selected by default. If you do not want to save the vCenter address, deselect the check box. 2. Click **Login**.

The connection to a saved vCenter instances is valid only for the current user session. You must enter the credentials of the source vCenter instances for each login session.

6. If a **Security Alert** dialog box appears, click **Yes**.
7. Click **Next**.
8. Select the virtual machines to import or clone.
   a) If you want to migrate more than one virtual machine, the selected virtual machines must be in the same power state.
   b) To keep a clone of the virtual machine on the source vCenter, select the **Keep VMs on the source vCenter (performs a VM clone operation).** check box.
   c) Click **Next** to continue.

   If you want to migrate more than one virtual machine, the selected virtual machines must be in the same power state.
9. Select the destination compute resource for this virtual machine migration and click **Next**.

   Possible targets include hosts and DRS clusters with any level of automation. If DRS is not enabled for a cluster, select a specific host in the cluster rather than selecting the cluster.

   Important:

   If the virtual machine that you migrate does not have an NVDIMM device but it uses PMem storage, you must select a host or cluster with available PMem resources, so that all PMem hard disks remain stored on a PMem datastore. Otherwise, all the hard disks use the storage policy and datastore selected for the configuration files of the virtual machine.

   Important:
   When you try to migrate a virtual machine that has an NVDIMM device or a vPMem disk to a host that does not have the proper license, the operation fails and the virtual machine is in an unmanageable state for 90 seconds. After 90 seconds, you can retry the migration, and select a destination host that is licensed to use PMem devices.
10. If a compatibility problem appears in the Compatibility pane, fix the problem or select another host or cluster for the migration.
11. Select the destination storage for the virtual machine migration.
    a) Select the storage type for the virtual machine configuration files and all the hard disks.

Mode	Description
Standard	All virtual disks are stored on a standard datastore.
PMem	All virtual disks are stored on the local PMem datastore of the host. Configuration files cannot be stored on a PMem datastore. You must additionally select a regular datastore for the configuration files of the virtual machine.
Hybrid	All PMem virtual disks remain stored on a PMem datastore. Your choice of a VM storage policy and your choice of a datastore affects non-PMem disks.

You can select the type of storage only if PMem or Hybrid storage types are available in the data center.

b) Select the format for the virtual machine's disks.

Option	Action
Same format as source	Use the same format as the source virtual machine.
Thick Provision Lazy Zeroed	Create a virtual disk in a default thick format. Space required for the virtual disk is allocated during creation. Any data remaining on the physical device is not erased during creation. Instead, it is zeroed out on demand on first write from the virtual machine.
Thick Provision Eager Zeroed	Create a thick disk that supports clustering features such as Fault Tolerance. Space required for the virtual disk is allocated at creation time. In contrast to the thick provision lazy zeroed format, the data remaining on the physical device is zeroed out during creation. It might take longer to create disks in this format than to create other types of disks.
Thin Provision	Use the thin provisioned format. At first, a thin provisioned disk uses only as much datastore space as the disk initially needs. If the thin disk needs more space later, it can expand to the maximum capacity allocated to it.

c) Select a virtual machine storage policy from the **VM Storage Policy** drop-down menu.

Storage policies specify storage requirements for applications that run on the virtual machine.

Important:
If the virtual machine hard disks use different storage policies, the new policy that you select only applies to non-PMem hard disks. PMem hard disks are migrated to the host-local PMem datastore of the destination host.

d) Select the datastore location where you want to store the virtual machine files.

Option	Action
Store all virtual machine files in the same location on a datastore.	Select a datastore from the list and click **Next**.
Store all virtual machine files in the same Storage DRS cluster.	1. Select a Storage DRS cluster. 2. If you want to migrate the virtual machine to a Storage DRS cluster and do not want to use Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 3. Click **Next**.
Store virtual machine configuration files and disks in separate locations.	1. Click **Configure per disk**. **Note:** You can use the **Configure per disk** option to downgrade from or upgrade to PMem storage. 2. For the virtual machine configuration file and for each virtual disk, select **Browse**, and select a datastore or Storage DRS cluster. **Note:** Configuration files cannot be stored on a PMem datastore. 3. If you want to migrate the virtual machine to a Storage DRS cluster and do not want to use Storage DRS with this virtual machine, select **Disable Storage DRS for this virtual machine** and select a datastore within the Storage DRS cluster. 4. Click **Next**.

12. If a compatibility problem appears in the Compatibility pane, fix the problem or select another destination storage for the migration.
13. Select the destination folder for the virtual machines and click **Next**.
14. Select the destination networks for the virtual machine migration.

Option	Action
Select a destination network for all VM network adapters connected to a valid source network.	1. Click the arrow in the **Destination Network** column and select **Browse**. 2. Select a destination network and click **OK**. 3. Click **Next**.
Select a different destination network for each VM network adapter connected to a valid source network.	1. Click **Advanced**. 2. Click the arrow in the **Destination Network** column and select **Browse**. 3. Select a destination network and click **OK**. 4. Click **Next**.

15. On the **Ready to complete** page, review the details and click **Finish**.

The virtual machines are moved or cloned to the destination folder in the current vCenter instance. You can monitor the migration process in the **Recent tasks** pane. If errors occur during the migration, the virtual machines revert to their original states and locations.

Migrating Virtual Machines Between Servers with DPU Devices

vSphere 8.0 introduces the VMware vSphere®Distributed Services Engine™ feature which allow offloading of some of your networking operations from an x86 host to a data processing unit (DPU). You can migrate virtual machines in a vSphere 8.0 environment with hosts that have data processing units (DPUs).

In vSphere 8.0, if you enable network offloads to a DPU device, you can use vSphere vMotion for migrating virtual machines when both hosts have DPU devices. To enable vMotion between hosts with DPU devices, you must perform multiple steps on the virtual machines, on the vCenter system, and on VMware NSX.

1. Create a vSphere Distributed Switch on a data center and enable the network offloads compatibility on the vSphere Distributed Switch. For more information about how to enable the network offloads compatibility on a host with a DPU device, see What is Network Offloads Compatibility in the *vSphere Networking* documentation.
2. Add to the switch only hosts with DPUs from the same vendor and of the same model.
3. Deploy NSX and configure an NSX transport node for the vSphere Distributed Switch. See the *NSX Installation Guide* documentation.
4. Enable the UPT support on the virtual machine that you want to migrate to and from a host with DPU devices. See *Add a Network Adapter to a Virtual Machine* in the *vSphere Virtual Machine Administration* documentation.

You can also use a DPU device on a host as a standard NIC. In this case, no additional configuration is required. You can use vSphere vMotion to migrate virtual machines to and from hosts with and without DPU devices.

What Is Encrypted vSphere vMotion

Encrypted vSphere vMotion secures confidentiality, integrity, and authenticity of data that is transferred with vSphere vMotion. vSphere supports encrypted vMotion of unencrypted and encrypted virtual machines across vCenter instances.

vSphere vMotion always uses encryption when migrating encrypted virtual machines. For virtual machines that are not encrypted, you can select one of the encrypted vSphere vMotion options.

What Is Encrypted in Encrypted vSphere vMotion

For encrypted disks, the data is transmitted encrypted in all cases. For unencrypted disks, the following applies:

- If disk data is transferred within a host, that is without changing the host, you change only the datastore, the transfer is unencrypted.
- If disk data is transferred between hosts and encrypted vMotion is used, the transfer is encrypted. If encrypted vMotion is not used the transfer is unencrypted.

For virtual machines that are encrypted, migration with vSphere vMotion always uses encrypted vSphere vMotion. You cannot turn off encrypted vSphere vMotion for encrypted virtual machines.

Encrypted vSphere vMotion States for Unencrypted Virtual Machines

For virtual machines that are not encrypted, you can set encrypted vSphere vMotion to one of the following states. The default is Opportunistic.

Disabled	Do not use encrypted vSphere vMotion.
Opportunistic	Use encrypted vSphere vMotion if the source and the destination hosts support it. Only ESX hosts of version 6.5 and later support encrypted vSphere vMotion.
Required	Allow only encrypted vSphere vMotion. If the source or the destination host does not support encrypted vSphere vMotion, migration with vSphere vMotion is not allowed.

When you encrypt a virtual machine, the virtual machine keeps a record of the current encrypted vSphere vMotion setting. If you later deactivate encryption for the virtual machine, the encrypted vMotion setting remains at Required until you change the setting explicitly. You can change the settings using **Edit Settings**.

> **Note:**
>
> Currently, you must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter instances. See *vSphere Web Services SDK Programming Guide* and *vSphere Web Services API Reference* documentation.

Migrating or Cloning Encrypted Virtual Machines Across vCenter Instances

vSphere vMotion supports migrating and cloning encrypted virtual machines across vCenter instances.

When migrating or cloning encrypted virtual machines across vCenter instances, the source and destination vCenter instances must be configured to share the key provider that was used to encrypt the virtual machine. In addition, the key provider name must be the same on both the source and destination vCenter instances, and must have the following characteristics:

- Standard key provider: The same key server (or key servers) must be in the key provider.
- vSphere Native Key Provider: Must have the same KDK.

  > **Note:**
  > You cannot clone or migrate an encrypted virtual machine using vSphere Native Key Provider to a standalone host, no matter that the source host resides in a cluster.

The destination vCenter ensures the destination ESX host has encryption mode set, ensuring the host is cryptographically "safe."

The following privileges are required when using vSphere vMotion to migrate or clone an encrypted virtual machine across vCenter instances.

- Migrating: **Cryptographic operations** > **Migrate** on the virtual machine
- Cloning: **Cryptographic operations** > **Clone** on the virtual machine

Also, the destination vCenter must have the **Cryptographic operations** > **EncryptNew** privilege. If the destination ESX host is not in "safe" mode, the **Cryptographic operations** > **RegisterHost** privilege must also be on the destination vCenter.

Certain tasks are not allowed when migrating virtual machines (non-encrypted or encrypted), either on the same vCenter or across vCenter instances.

- You cannot change the VM Storage Policy.
- You cannot perform a key change.

  > **Note:**
  > You can change the VM Storage Policy while cloning virtual machines.

vSphere Native Key Provider vMotion and Cross-vCenter vMotion

vSphere Native Key Provider supports vMotion and Encrypted vMotion across ESX hosts. Cross-vCenter vMotion is supported if vSphere Native Key Provider is configured on the destination host.

Encrypted vMotion and Intel QuickAssist Technology (QAT) Hardware Accelerator

The vMotion encryption and decryption tasks, which use CPU resources, are now offloaded to the hardware devices. Some processors, for example, 4th Gen Intel Xeon Scalable Processors and 5th Gen Intel Xeon Scalable Processors, have built-in QAT accelerators. Starting with vSphere 9.1, if your processor has QAT accelerator and the device is available for vMotion, by default the crypto operation for ecrypted vMotion is offloaded to the QAT accelerator. This reduces the CPU consumption for the vMotion task. If the QAT accelerator is needed for a virtual machine operation at the same time as an encrypted vMotion task, the vMotion task does not interrupt the virtual machine operation.

The feature is activated by default during new deployment and after an upgrade to vSphere 9.1. You can see the following message in the vmkernel logs:

```
DAS Crypto AEAD session handle created successfully. Crypto workload will be offloaded.
```

vSphere is compliant with the Federal Information Processing Standards (FIPS). If you want to make your end-to-end solution compliant with FIPS, you must choose FIPS-compliant hardware. If your environment requires FIPS compliance, you must validate that third-party hardware solutions, including Intel QAT, meet the necessary standards.

How to Activate Encrypted vSphere vMotion on Your Virtual Machine

You can activate encrypted vSphere vMotion during virtual machine creation. You can later change the encrypted vMotion state from the virtual machine settings.

Encrypted vMotion is supported only in vSphere 6.5 and later.

You can change the encrypted vMotion state only for virtual machines that are not encrypted.

1. In the vSphere Client, click the main navigation menu
   (**),**
   and select **Inventory**.
2. Select **Hosts and Clusters**, and navigate to the virtual machine.
3. Right-click the virtual machine and select **Edit Settings**.
4. Select **VM Options**.
5. Click **Encryption**, and select an option from the **Encrypted VMotion** drop-down menu.

Disabled	Do not use encrypted vMotion.
Opportunistic	Use encrypted vMotion if source and destination hosts support it. Only ESX hosts of version 6.5 and later support encrypted vMotion.
Required	Allow only encrypted vMotion. If the source or destination host does not support encrypted vMotion, migration with vMotion fails.

How to Isolate Traffic for Migrating Your Virtual Machines

You can use the vSphere vMotion TCP/IP stack to isolate traffic for vMotion and the provisioning TCP/IP stack to isolate traffic for cold migration, VM clones, and snapshots.

How to Place vSphere vMotion Traffic on the vMotion TCP/IP Stack of Your ESX Host

Learn how to use the vMotion TCP/IP stack to isolate traffic for vMotion and to assign a dedicated default gateway, routing table, and DNS configuration for this traffic. To enable the vMotion TCP/IP stack, assign a new VMkernel adapter to it.

Verify that the host is running ESXi 6.0 or later

By using a separate TCP/IP stack, you can handle vMotion traffic according to the topology of the network and as required for your organization:

- Route the traffic for migration of powered on virtual machines by using a default gateway. The gateway might be different from the gateway assigned to the default stack on the host.
- Assign a separate set of buffers and sockets.
- Avoid routing table conflicts that might otherwise appear when many features are using a common TCP/IP stack.
- Isolate traffic to improve security.

1. In the vSphere Client, click the main navigation menu ( ), and select **Inventory**.
2. Select **Hosts and Clusters**, and select the host.
3. Click the **Configure** tab.
4. Select **Networking**, and click **VMkernel adapters**.
5. Click **Add networking**.
6. On the Select connection type page, select **VMkernel Network Adapter** and click **Next**.
7. On the **Select target device** page, select the switch for the VMkernel adapter, and click **Next**.

Option	Description
Select an existing network	Use the physical adapter configuration of an existing distributed port group to send data from the VMkernel adapter to the external network.
Select an existing standard switch	Use the physical adapter configuration for the VMkernel adapter of an existing standard switch.
New vSphere standard switch	Assign a new physical adapter configuration for the VMkernel adapter on a new standard switch.

8. On the Port properties page, select **vMotion** from the **TCP/IP stack** drop-down menu.

   The vMotion traffic becomes the only service that is enabled. You cannot use this VMkernel adapter for traffic types other than vMotion.
9. Set the label, VLAN ID, and IP mode of the VMkernel adapter, and click **Next**.
10. Optional: On the IPv4 settings page, select an option for obtaining IP addresses.

Option	Description
Obtain IPv4 settings automatically	Use DHCP to obtain IP settings. A DHCP server must be present on the network.
Use static IPv4 settings	Enter the IPv4 IP address and subnet mask for the VMkernel adapter. The VMkernel Default Gateway and DNS server addresses for IPv4 are obtained from the selected TCP/IP stack. Select the **Override default gateway for this adapter** check box and enter a gateway address, if you want to specify a different gateway for the VMkernel adapter. **Note:** Selected netstack should have the default gateway explicitly on each host.

11. Optional: On the IPv6 settings page, select an option for obtaining IPv6 addresses.

Option	Description
Obtain IPv6 addresses automatically through DHCP	Use DHCP to obtain IPv6 addresses. A DHCPv6 server must be present on the network.
Obtain IPv6 addresses automatically through Router Advertisement	Use router advertisement to obtain IPv6 addresses. In ESX 6.5 and later router advertisement is enabled by default and supports the M and O flags in accordance with RFC 4861.
Static IPv6 addresses	1. Click **Add IPv6 address** to add a new IPv6 address. 2. Enter the IPv6 address and subnet prefix length, and click **OK**. 3. To change the VMkernel default gateway, click **Override default gateway for this adapter**. The VMkernel Default Gateway address for IPv6 is obtained from the selected TCP/IP stack.

12. Review your settings selections on the Ready to complete page and click **Finish**.

After you create a VMkernel adapter on the vMotion TCP/IP stack, you can use only this stack for vMotion on this host. The VMkernel adapters on the default TCP/IP stack are deactivated for the vMotion service. If a live migration uses the default TCP/IP stack while you are configuring VMkernel adapters with the vMotion TCP/IP stack, the migration completes successfully. However, the involved VMkernel adapters on the default TCP/IP stack are deactivated for future vMotion sessions.

Assign a default gateway, and configure the DNS settings, congestion control, and maximum number of connections for the vMotion TCP/IP stack.

For more information on how to change the configuration of a TCP/IP stack on a host, see Change the Configuration of an TCP/IP Stack on a Host in the *vSphere Networking* documentation.

How to Place Traffic for Cold Migration, Cloning, and Snapshots on the Provisioning TCP/IP Stack

Learn how to use the provisioning TCP/IP stack to isolate traffic for cold migration, VM clones, snapshots, and cold data in hot migration, and to assign a dedicated default gateway, routing table, and DNS configuration for this traffic. To enable the Provisioning TCP/IP stack, assign a new VMkernel adapter to it.

Verify that the host is running ESXi 6.0 or later

By using a separate TCP/IP stack, you can handle vMotion traffic according to the topology of the network and as required for your organization:

- Route the traffic for migration of powered on virtual machines by using a default gateway. The gateway might be different from the gateway assigned to the default stack on the host.
- Assign a separate set of buffers and sockets.
- Avoid routing table conflicts that might otherwise appear when many features are using a common TCP/IP stack.
- Isolate traffic to improve security.

1. In the vSphere Client, navigate to the host.
2. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
3. Select **Hosts and Clusters, and select the host**.
4. Click the **Configure** tab.
5. Select **Networking**, and click **VMkernel adapters**.
6. Click **Add networking**.
7. On the Select connection type page, select **VMkernel Network Adapter** and click **Next**.
8. On the **Select target device** page, select the switch for the VMkernel adapter, and click **Next**.

Option	Description
Select an existing network	Use the physical adapter configuration of an existing distributed port group to send data from the VMkernel adapter to the external network.
Select an existing standard switch	Use the physical adapter configuration for the VMkernel adapter of an existing standard switch.
New vSphere standard switch	Assign a new physical adapter configuration for the VMkernel adapter on a new standard switch.

9. On the Port properties page, select **Provisioning** from the **TCP/IP stack** drop-down menu.

   The provisioning traffic becomes the only service that is enabled. You cannot use this VMkernel adapter for traffic types other than provisioning.
10. Set the label, VLAN ID, and IP mode of the VMkernel adapter, and click **Next**.
11. Optional: On the IPv4 settings page, select an option for obtaining IP addresses.

Option	Description
Obtain IPv4 settings automatically	Use DHCP to obtain IP settings. A DHCP server must be present on the network.
Use static IPv4 settings	Enter the IPv4 IP address and subnet mask for the VMkernel adapter. The VMkernel Default Gateway and DNS server addresses for IPv4 are obtained from the selected TCP/IP stack. Select the **Override default gateway for this adapter** check box and enter a gateway address, if you want to specify a different gateway for the VMkernel adapter. **Note:** Selected netstack should have the default gateway explicitly on each host.

12. Optional: On the IPv6 settings page, select an option for obtaining IPv6 addresses.

Option	Description
Obtain IPv6 addresses automatically through DHCP	Use DHCP to obtain IPv6 addresses. A DHCPv6 server must be present on the network.
Obtain IPv6 addresses automatically through Router Advertisement	Use router advertisement to obtain IPv6 addresses. In ESX 6.5 and later router advertisement is enabled by default and supports the M and O flags in accordance with RFC 4861.
Static IPv6 addresses	1. Click **Add IPv6 address** to add a new IPv6 address. 2. Enter the IPv6 address and subnet prefix length, and click **OK**.

Option	Description
	3. To change the VMkernel default gateway, click **Override default gateway for this adapter**. The VMkernel Default Gateway address for IPv6 is obtained from the selected TCP/IP stack.

13. Review your settings selections on the Ready to complete page and click **Finish**.

After you create a VMkernel adapter on the provisioning TCP/IP stack, you can use only this stack for cold migration, cloning, and snapshots on this host. The VMkernel adapters on the default TCP/IP stack are deactivated for the provisioning service. If a live migration uses the default TCP/IP stack while you configure VMkernel adapters with the provisioning TCP/IP stack, the data transfer completes successfully. However, the involved VMkernel adapters on the default TCP/IP stack are deactivated for future cold migration, cross-host cloning, and snapshot sessions.

vCenter Limits on Simultaneous Migrations

vCenter places limits on the number of simultaneous virtual machine migration and provisioning operations that can occur on each host, network, and datastore.

Each operation, such as a migration with vMotion or cloning a virtual machine, is assigned a resource cost. Each host, datastore, or network resource, has a maximum cost that it can support at any one time. Any new migration or provisioning operation that causes a resource to exceed its maximum cost does not proceed immediately, but is queued until other operations complete and release resources. Each of the network, datastore, and host limits must be satisfied for the operation to proceed.

vMotion without shared storage, migrating virtual machines to a different host and datastore simultaneously, is a combination of vMotion and Storage vMotion. This migration inherits the network, host, and datastore costs associated with those operations. vMotion without shared storage is equivalent to a Storage vMotion with a network cost of 1.

Network Limits

Network limits apply only to migrations with vMotion. Network limits depend on the version of ESX and the network type. All migrations with vMotion have a network resource cost of 1.

Table 99: Network Limits for Migration with vMotion

Operation	ESX Version	Network Type	Maximum Cost
vMotion	7.0, 8.0, 9.0, 9.1	1GigE	4
vMotion	7.0, 8.0, 9.0, 9.1	10GigE	8

Datastore Limits

Datastore limits apply to migrations with vMotion and with Storage vMotion. A migration with vMotion has a resource cost of 1 against the shared virtual machine's datastore. A migration with Storage vMotion has a resource cost of 16 against the source datastore and 16 against the destination datastore.

Table 100: Datastore Limits and Resource Costs for vMotion and Storage vMotion

Operation	ESX Version	Maximum Cost Per Datastore	Datastore Resource Cost
vMotion	7.0, 8.0, 9.0, 9.1	128	1
Storage vMotion	7.0, 8.0, 9.0, 9.1	128	16

Host Limits

Host limits apply to migrations with vMotion, Storage vMotion, and other provisioning operations such as cloning, deployment, and cold migration. All hosts have a maximum cost per host of 8. For example, on an ESX 7.0 host, you can perform 2 Storage vMotion operations, or 1 Storage vMotion and 4 vMotion operations.

Table 101: Host Migration Limits and Resource Costs for vMotion, Storage vMotion, and Provisioning Operations

Operation	ESX Version	Derived Limit Per Host	Host Resource Cost
vMotion	7.0, 8.0, 9.0, 9.1	8	1
Storage vMotion	7.0, 8.0, 9.0, 9.1	2	4
vMotion Without Shared Storage	7.0, 8.0, 9.0, 9.1	2	4
Other provisioning operations	7.0, 8.0, 9.0, 9.1	8	1

vMotion Migration Compatibility Checks

During migration, use the **Migrate Virtual Machine** wizard to view information about the compatibility checks carried out using various criteria between the destination host or cluster and the migrating virtual machine.

When you select a host or a cluster, the Compatibility panel at the bottom of the **Migrate Virtual Machine** wizard displays information about the compatibility of the selected host or cluster with the virtual machine's configuration.

Compatibility Check Results

If the virtual machine is compatible, the panel displays the message `Compatibility checks succeeded`. If the virtual machine is not compatible with either the host's or cluster's configured networks or datastores, the compatibility window might display both warnings and errors:

- Warning messages do not stop migration. Often the migration is justified and you can continue with the migration despite the warnings.
- Errors might stop migration if no error-free destination hosts are available among the selected destination hosts. In this case, if you click **Next**, the wizard displays the compatibility errors again, and you cannot proceed to the next step.

Compatibility Checks During Migration Setup

When you attempt to move only the compute resource, the **Migrate Virtual Machine** wizard examines the source and destination hosts, the target resource pool, the datastore, and the network. When you attempt to move only the storage, the wizard checks the compatibility of the same objects except for the network.

When you move compute resources and storage together, the **Migrate Virtual Machine** wizard runs fewer compatibility checks. For example, if you move the compute resource, you select the target host or cluster under a vCenter instance. The wizard performs all necessary validation only against the selected host, and does not check the datastores available on the destination host. When you attempt to move the virtual machine to a cluster, the **Migrate Virtual Machine** wizard examines the compatibility against the host recommendation from vSphere DRS. The wizard directly validates the compatibility of the target datastore when you select it later.

Another compatibility check is whether vMotion is enabled on the source and target hosts.

Compatibility Checks for Virtual Hardware

Effects of a specific host CPU feature on compatibility depend on whether ESX exposes or hides them from virtual machines.

- Features that are exposed to virtual machines are not compatible when they do not match on the source and target hosts.
- Features that are not exposed to virtual machines are considered as compatible regardless of whether they match on the hosts.

Specific items of virtual machine hardware can also cause compatibility problems. For example, a virtual machine using an Enhanced VMXNET virtual NIC cannot be migrated to a host running a version of ESX that does not support Enhanced VMXNET.

CPU Compatibility and vSphere Enhanced vMotion Compatibility

vCenter performs compatibility checks before it allows migration of running or suspended virtual machines to another host. Compatibility checks ensure that the virtual machine is compatible with the target host CPU.

When you initiate a migration with vMotion or a migration of a suspended virtual machine, the **Migrate Virtual Machine** wizard checks the destination host for compatibility. If compatibility problems prevent migration, the wizard displays an error message.

The CPU instruction set available to the operating system and to applications running in a virtual machine is determined at the time that a virtual machine is powered on. This CPU feature set is based on the following items:

- Host CPU family and model.
- Settings in the BIOS that might deactivate CPU features.
- ESX version running on the host.
- The virtual hardware compatibility setting of the virtual machine.
- The guest operating system of the virtual machine.

CPUs have new instructions or features added in each new CPU generation. While a virtual machine is powered-on, the set of features available to the virtual machine remains constant regardless of what host CPU the virtual machine runs on.

When you migrate a powered-on or suspended virtual machine, the set of CPU features available on the target host must include all of the features available to the virtual machine when it was powered-on prior to the migration. A compatibility check is performed to ensure that after you migrate a virtual machine, the target host CPU will support all of the instructions and features that the powered-on virtual machine requires. If the target host CPU does not supports all of them, you cannot proceed with the migration.

When you migrate a virtual machine by using vMotion, the processors of the target host must provide the same instructions to the virtual machine after migration that the processors of the source host provided before migration. Clock speed, cache size, and number of cores can differ between source and target processors.

To improve CPU compatibility between hosts of varying CPU feature sets, some host CPU features can be hidden from the virtual machine by placing the host in an Enhanced vMotion Compatibility (EVC) cluster. If the hosts in a cluster have processors from the same CPU vendor but different CPU generations, you can use Enhanced vMotion Compatibility to make all host CPUs migration compatible. When you configure EVC on a cluster, all the hosts in the cluster become migration compatible, even if they are a mixture of CPU generations. The host CPUs in that cluster are treated as if they are of the same generation and provide the same set of instructions and features.

For example, if a cluster contains hosts with Intel CPUs of different generations: Intel Cascade Lake, Intel Ice Lake, and Intel Sapphire Rapids, after you configure EVC, all hosts in the cluster can appear as Intel Cascade Lake during virtual machine power-on and migration.

Pre-Defined EVC Mode

The EVC mode of a cluster can be chosen from a list of pre-defined modes that closely match the CPU generations from Intel or AMD, such as Intel Cascade Lake and AMD Zen 2. After you select a pre-defined EVC mode and apply it to the cluster, you can only add ESX hosts with CPUs that have the same or greater features than that of the EVC mode of the cluster. After you add a host to a cluster with pre-defined EVC mode, the host CPU features that are available to a virtual machine are restricted to the features of the EVC mode. You can also select a pre-defined vSGA EVC mode and apply it to all hosts in the cluster. For more information about vSGA, see Virtual Shared Graphics Acceleration.

Note:

Pre-defined EVC modes closely match CPU generations. However, CPUs from the same generation might support a close but not identical set of instructions or features. Pre-defined EVC modes per generation match the highest set of instructions and features for the specified CPU generation. Hosts with CPUs from the same generation but with a less rich feature set might not be allowed to the cluster with a pre-defined EVC mode for this generation. In such cases you can use custom EVC mode.

Custom EVC Mode

Starting with vSphere 9.0, you can also use a custom EVC type. With the custom EVC type, you can select a set of hosts or clusters that are used to create a custom EVC mode based on the highest set of CPU and vSGA features common to all selected hosts and hosts included in the selected clusters. By using a custom EVC mode, you can select specific hosts or clusters, and their host CPUs are used to construct the new custom EVC mode.

A custom EVC mode can be created from a set of hosts or clusters within the vCenter instance, and from hosts or clusters managed by other vCenter instances if the vCenter instances operate in linked mode. However, the created custom EVC mode can only be applied to clusters managed by the current vCenter instance.

You can apply pre-defined or custom EVC modes to clusters and virtual machines.

CPU Families and Feature Sets Compatibility with vSphere vMotion

Processors are grouped into families. Processors within a given family generally have similar feature sets.

Processor vendors define processor families. You can distinguish different processor versions within the same family by comparing the processors' model, stepping level, and extended features. Each vendor's CPU generations, identifiable by family, model and stepping, add new instructions and features.

By default, vCenter does compatibility checks to ensure that the CPU features of a host are sufficient:

- To power-on a virtual machine on that host.
- For the host to be the target host of a vMotion migration.
- For the host to be the target host of migration of a suspended virtual machine.

For more information on identifying Intel processors and their features, see *How to Identify My Intel Processor*, available from Intel. For more information on identifying AMD processors and their features, see *Obtaining Processor Information Via the CPUID Instruction*, available from AMD.

Enhanced vMotion Compatibility

You can use the Enhanced vMotion Compatibility (EVC) feature to help ensure vMotion compatibility between all hosts in a cluster. EVC ensures that all hosts in a cluster present the same CPU feature set to virtual machines, even if the actual CPUs on the hosts differ. Using EVC prevents migrations with vMotion from failing because of incompatible CPUs.

When you configure EVC on a cluster, you configure all host processors in the cluster to present the same feature set. The EVC mode must be equivalent to, or a subset of, the feature set of the host with the smallest feature set in the cluster.

Activating EVC only affects processor features that affect vMotion compatibility. Activating EVC does not prevent a virtual machine from taking advantage of faster processor speeds or increased numbers of CPU cores that might be available on newer hosts.

EVC cannot prevent virtual machines from accessing hidden CPU features in all circumstances. Applications that do not follow CPU vendor recommended methods of feature detection might behave unexpectedly in an EVC environment. VMware EVC cannot be supported with ill-behaved applications that do not follow the CPU vendor recommendations. For more information about creating well-behaved applications, see *What is an ill-behaved application, and why does it affect EVC?*, in Broadcom Knowledge Base article 313545.

The EVC feature for Virtual Shared Graphics Acceleration (vSGA) allows multiple virtual machines to share GPUs installed on ESX hosts and leverage the 3D graphics acceleration capabilities. vSGA enables efficient use of hardware acceleration by grouping virtual machines with different performance requirements on one GPU. For more information about vSGA, see Virtual Shared Graphics Acceleration.

Pre-defined and Custom EVC Modes

Starting with vSphere 9.0, in addition to pre-defined EVC modes, you can also use a custom EVC mode. With the pre-defined EVC mode, you can choose from a list of EVC and vSGA modes which closely match vendors' CPU generations. With the custom EVC mode, you can select a set of hosts or clusters from which to construct a custom EVC mode based on the highest set of CPU and vSGA features common to all selected hosts. You cannot modify the feature sets of the EVC types.

Enhanced vMotion Compatibility Requirements for Hosts

To improve CPU compatibility between hosts that have varying CPU feature sets, you can place the host in a cluster with activated Enhanced vMotion Compatibility (EVC). Hosts in an EVC cluster and hosts that you add to an existing EVC cluster must meet EVC requirements.

- To activate or change the EVC mode of a cluster, power off all virtual machines in the cluster that require a feature set greater than the EVC mode that you intend to enable. You can also migrate these virtual machines out of the cluster.
- All hosts in the cluster must meet the following requirements:

Requirements	Description
Supported ESX version	ESX 7.0 or later.
vCenter	The host must be connected to a vCenter system.
CPUs	A single vendor, either AMD or Intel.
Advanced CPU features enabled	Enable these CPU features in the BIOS if they are available: • Hardware virtualization support (AMD-V or Intel VT) • AMD No eXecute(NX) • Intel eXecute Disable (XD) **Note:** Hardware vendors sometimes deactivate particular CPU features in the BIOS by default. You might have problems enabling EVC because the EVC compatibility checks detect the absence of features that are expected to be present for a particular CPU. If you cannot enable EVC on a system with a compatible processor, ensure that all features are enabled in the BIOS.
Supported CPUs for the EVC mode that you want to enable	To check EVC support for a specific processor or server model, see the *Broadcom Compatibility Guide* at https://compatibilityguide.broadcom.com/.
Configured for vMotion	See Host Configuration for vSphere vMotion.

- Custom EVC is available in vCenter instances of version 9.0 or later.

How to Configure the EVC Mode of an Existing Cluster

Learn how to activate or change the vSphere Enhanced vMotion Compatibility (EVC) mode on an existing cluster to ensure vMotion CPU compatibility between the hosts in the cluster.

- Verify that the hosts in the cluster meet the requirements listed in Enhanced vMotion Compatibility Requirements for Hosts.
- Verify that all hosts in the cluster are connected and registered on vCenter. The cluster cannot contain a disconnected host.
- Verify that all hosts in the cluster have supported CPUs for the EVC mode you want to enable. For a list of supported CPUs, see the Broadcom Compatibility Guide at https://compatibilityguide.broadcom.com/.
- Power off all virtual machines with no EVC mode or with an EVC mode that is greater than the EVC mode that you plan to enable on the cluster. To determine the EVC mode of all virtual machines on the hosts in the cluster, see How to Determine the EVC Mode of Your Virtual Machine.

- When you change the EVC mode on a cluster, virtual machines must be in the following power states, depending on whether you raise or lower the EVC mode.

EVC Mode	Virtual Machine Power Action
Raise the EVC mode to a CPU baseline with more features.	Running virtual machines can remain powered on. New EVC mode features are not available to the virtual machines until they are powered off and powered back on again. A full power cycling is required. Rebooting the guest operating system or suspending and resuming the virtual machine is not sufficient. **Tip:** You can configure a virtual machine to power cycle when its guest OS is rebooted, by setting the `vmx.reboot.powerCycle` VM parameter to `TRUE`. When the virtual machine is powered back on, this configuration parameter is removed. To edit the virtual machine configuration settings, you can use the VMware Host Client. See *Edit the Configuration File Parameters in the VMware Host Client* topic in the *vSphere Single Host Management - VMware Host Client* guide. For information on how to set this parameter to a group of virtual machines using VMware PowerCLI, see the VMware vSphere Blog post.
Lower the EVC mode to a CPU baseline with fewer features.	Power off virtual machines if they are powered on and running at a higher EVC mode than the one you intend to enable.

- If you want to use custom EVC mode, verify that the vCenter version is 9.0 or later.

Several EVC approaches are available to ensure CPU compatibility:

- You can raise the EVC mode to expose more CPU features.
- You can lower the EVC mode to hide CPU features and increase compatibility.
- If all the hosts in a cluster are compatible with a newer EVC CPU or Graphics (vSGA) mode, you can change the EVC CPU or Graphics (vSGA) mode of an existing EVC cluster.

For more information about vSGA, see Virtual Shared Graphics Acceleration.

Note:

When you take a snapshot of a virtual machine in an EVC cluster, keep in mind the following use cases:

- If you take a snapshot of a running virtual machine before an EVC downgrade, an attempt to revert to that snapshot after the EVC downgrade fails and the virtual machine is left in a suspended state.
- If you take a snapshot of a virtual machine before an EVC upgrade, you can revert to that snapshot before or after the EVC upgrade.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Inventory**.
2. Select **Hosts and Clusters**.
3. Select a cluster in the vSphere inventory.
4. Power off all the virtual machines on the hosts with feature sets greater than the EVC mode.
5. Click the **Configure** tab.
6. Under Configuration, select VMware EVC, and click **Edit**.
7. If you want to select a pre-defined EVC type, select **Pre-defined** from the **EVC type**drop-down menu.
   a) From the **Host type**drop-down menu, select whether you want to activate the EVC mode for AMD hosts or Intel hosts.
   b) From the **CPU Mode** drop-down menu, select a CPU feature set.
   c) From the **Graphics Mode (vSGA)** drop-down menu, select a graphics feature set.

Option	Description
Baseline Graphics	Applies the Baseline Graphics feature set that includes features through Direct3D 10.1/OpenGL 3.3. **Note:** To configure the vSGA mode to apply the Baseline Graphics set that includes features through Direct3D 10.1/OpenGL 3.3, the virtual machine must be compatible with ESX 6.5 or later.
D3D 11.0 class features	Applies the baseline graphics feature set that includes features through Direct3D 11.0/OpenGL 4.3. **Note:** When you create a cluster and you enable EVC graphics mode Direct3D 11.0/OpenGL 4.3 class features, you can add only ESX 8.0 hosts that support Direct3D 11.0/OpenGL 4.3 to the cluster. When you try to add an ESX 8.0 host that does not support Direct3D 11.0/OpenGL 4.3 to the cluster, the operation fails with an error message.

8. If you want to configure a custom EVC mode, select Custom from the EVC type drop down menu.
   a) From the list of inventory objects, select the hosts or clusters to be used to construct the custom EVC mode feature set.

      Note:

      If your vCenter instances are part of a vCenter linking group, you can select hosts or clusters from any vCenter instance part of the vCenter linking group.

      If some of your clusters have EVC modes applied, you cannot select specific hosts from that cluster but only the whole cluster.
9. Click **Next**.

   A validation process starts.

   If the EVC CPU mode or the vSGA mode that you selected cannot be applied, the **Compatibility** pane displays the reason, and the relevant hosts for each reason.

10. Review the EVC mode details and click **Finish**.

How to Configure the EVC Mode of a Virtual Machine

Per virtual machine EVC is deactivated by default. You can activate, deactivate, and change the EVC mode of a virtual machine to ensure its seamless migration across clusters, vCenter systems, and data centers that have different processors.

- Power off the virtual machine.
- Verify that the virtual hardware version is 14 or later.

The per virtual machine EVC feature facilitates the migration of the virtual machine beyond the cluster and across vCenter systems and data centers that have different CPU generations. The EVC mode of a virtual machine is independent from the EVC mode defined at the cluster level. The cluster-based EVC mode limits the CPU features a host exposes to virtual machines. The per virtual machine EVC mode determines the set of host CPU features that a virtual machine requires to power on and migrate. By default, when you power on a newly created virtual machine, it inherits the feature set of its parent EVC cluster or host. However, you can change the EVC mode for each virtual machine separately. You can raise or lower the EVC mode of a virtual machine. Lowering the EVC mode increases the CPU compatibility of the virtual machine. You can also use the API calls to customize the EVC mode further.

There are several differences between the way the EVC feature works at the host cluster level and at the virtual machine level.

- Unlike cluster-based EVC, you can change the per-VM EVC mode only when the virtual machine is powered off.
- With cluster-based EVC, when you migrate a virtual machine out of the EVC cluster, a power cycle resets the EVC mode that the virtual machine has. With Per-VM EVC, the EVC mode becomes an attribute of the virtual machine. A power cycle does not affect the compatibility of the virtual machine with different processors.
- When you configure EVC at the virtual machine level, the per virtual machine EVC mode overrides cluster-based EVC. If you do not configure per virtual machine, when you power on the virtual machine, it inherits the EVC mode of its parent EVC cluster or host.
- If a virtual machine is in an EVC cluster and the per virtual machine EVC is also enabled, the EVC mode of the virtual machine cannot exceed the EVC mode of the EVC cluster in which the virtual machine runs. The baseline feature set that you configure for the virtual machine cannot contain more CPU features than the baseline feature set applied to the hosts in the EVC cluster. For example, if you configure a cluster with the Intel "Merom" Generation EVC mode, you should not configure a virtual machine with any other Intel baseline feature set. All other sets contain more CPU features than the Intel "Merom" Generation feature set and as a result of such configuration, the virtual machine fails to power on.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Select **Hosts and Clusters**.
3. Navigate to a virtual machine in the inventory, and click the **Configure** tab.
4. Under Configuration, select **VMware EVC**.

   The pane shows details about the EVC mode of the virtual machine and CPUID details.

   Important:
   For newly created virtual machines, the EVC mode that shows in the **VMware EVC** pane is deactivated.

   For powered off virtual machines, the **VMware EVC** pane always shows the EVC status defined at the virtual machine level.

   For powered on virtual machines with per-VM EVC activated, the VMware EVC pane shows the EVC status defined at the virtual machine level.

   For powered on virtual machines with per-VM EVC deactivated, the VMware EVC pane shows the EVC mode that the virtual machine inherits from its parent EVC cluster or host.

5. Click the **Edit** button.

   The **Configure EVC mode** dialog box appears.

6. If you want to select a pre-defined EVC type, select **Pre-defined** from the **EVC type**drop-down menu.
   a) From the **Host type**drop-down menu, select whether you want to activate the EVC mode for AMD hosts or Intel hosts.
   b) From the **CPU Mode** drop-down menu, select the baseline CPU feature set that you want to enable for the cluster.

      Important:

      If the virtual machine is in an EVC cluster and the per-VM EVC mode exceeds the EVC mode for the cluster, the virtual machine fails to power on. The baseline CPU feature set for the virtual machine must not contain more CPU features than the baseline CPU feature set of the cluster.

   c) From the **Graphics Mode (vSGA)** drop-down menu, select a baseline graphics feature set.

Option	Description
Baseline Graphics	Applies the Baseline Graphics feature set that includes features through Direct3D 10.1/OpenGL 3.3. **Note:** To configure the vSGA mode to apply the Baseline Graphics set that includes features through Direct3D 10.1/OpenGL 3.3, the virtual machine must be compatible with ESX 7.0 Update 1 or earlier.
D3D 11.0 class features	Applies the baseline graphics feature set that includes features through Direct3D 11.0/OpenGL 4.3 **Note:** To configure the vSGA mode to apply the Baseline Graphics set that includes features through Direct3D 11.0/OpenGL 4.3, verify that the virtual machine is compatible with ESX 8.0 or later and has installed VMware Tools 12.0.0 or later. To power on a virtual machine, configured with Direct3D 11.0/OpenGL 4.3, verify that the ESX host graphics hardware is available.

7. If you want to configure a custom EVC type, select **Custom** from the **EVC type** drop-down menu.
   a) From the list of inventory objects, select the hosts or clusters to be used to construct the EVC mode feature set.

      Note:

      If your vCenter instances are part of a vCenter linking group group, you can select hosts or clusters from any vCenter instance part of the vCenter linking group group.

      If some of your clusters have EVC modes applied, you cannot select specific hosts from that cluster but only the whole cluster.

8. Click **Next**.

   A validation process starts.

   If the EVC CPU or the vSGA mode that you selected cannot be applied, the **Compatibility** pane displays the reason, and the relevant hosts for each reason.

9. Review the EVC mode details and click **Finish**.

How to Determine the EVC Mode of Your Virtual Machine

The EVC mode of a virtual machine determines the CPU and graphics features that a host must have in order for the virtual machine to migrate to that host and power on. The EVC mode of a virtual machine is independent from the EVC mode that you configure for the cluster in which the virtual machine runs.

The EVC mode of a virtual machine is determined when the virtual machine powers on. At power-on, the virtual machine also determines the EVC mode of the cluster in which it runs. If the EVC mode of a running virtual machine or the entire EVC cluster is raised, the virtual machine does not change its EVC mode until it is powered off and powered on again. This means that the virtual machine does not use any CPU features exposed by the new EVC mode until the virtual machine is powered off and powered on again.

For example, you create an EVC cluster that contains hosts with Intel processors and you set the EVC mode to Intel "Merom" Generation (Xeon Core 2). When you power on a virtual machine in this cluster, it runs in the Intel Merom Generation (Xeon Core 2) EVC mode. If you raise the EVC mode of the cluster to Intel "Penryn" Generation (Xeon 45 nm Core 2), the virtual machine retains the lower Intel "Merom" Generation (Xeon Core 2) EVC mode. To use the feature set of the higher EVC mode, such as SSE4.1, the virtual machine must be powered off and powered on again.

1. In the vSphere Client, click the main navigation menu

   (**),**

   and select **Inventory**.
2. Select **Hosts and Clusters**.
3. Navigate to a cluster or a host in the inventory.
4. Click the **VMs** > **Virtual Machines** tab.

   A list of all virtual machines in the selected cluster or on the selected host appears.
5. To verify the status of the CPU mode, check the **EVC CPU Mode** column.
   a) If the column is not visible, click **Manage Columns** at the bottom left corner of the **Virtual Machines** table.

      The **Show Columns** pop-up appears.
   b) To show the **EVC CPU Mode** column, locate and select the respective check box from the list.

   The **EVC CPU Mode** column shows the CPU modes of all virtual machines in the cluster or on the host.

   Important:
   For each virtual machine, the **EVC CPU Mode** column displays the EVC mode defined at the virtual machine level.

   However, if you do not configure per-VM EVC for a virtual machine, the virtual machine inherits the EVC mode of its parent cluster or host. As a result, for all virtual machines that do not have per-VM EVC configured, the **EVC CPU Mode** column displays the inherited EVC mode of the parent host or cluster.

   If the virtual machine is in an EVC cluster, the EVC mode that you see in the **EVC CPU Mode** column is defined in the following manner.

   - When the virtual machine is powered on, the **EVC CPU Mode** column displays either the per-VM EVC mode, or the cluster-level EVC mode.

Per-VM EVC	Cluster-Level EVC	EVC Mode for the Virtual Machine
Activated	Activated	Enabled. The **EVC CPU Mode** column displays the EVC mode of the virtual machine.
Deactivated	Activated	Enabled. The **EVC CPU Mode** column displays the EVC mode of the EVC cluster.

- When the virtual machine is powered off, the **EVC CPU Mode** column displays the per-VM EVC mode. If per-VM EVC is deactivated, the **EVC CPU Mode** column for the virtual machine is empty.

When the virtual machine is not in an EVC cluster and per-VM EVC is not configured, the EVC mode that you see in the **EVC CPU Mode** column is defined in the following manner.

- When the virtual machine is powered on, the **EVC CPU Mode** column displays the EVC mode of the parent host.
- When the virtual machine is powered off, the **EVC CPU Mode** column is empty.

6. To verify the status of the graphics mode, check the **EVC Graphics Mode (vSGA)** column.
   a) If the column is not visible, click **Manage Columns** at the bottom left corner of the **Virtual Machines** table.
      The **Show Columns** pop-up appears.
   b) To show the **EVC Graphics Mode (vSGA)** column, locate and select the respective check box from the list.

   The **EVC Graphics Mode (vSGA)** column displays the baseline graphics features set. To view the baseline graphics, you must enable **3D graphics** in the virtual machine.

   For information about configuring 3D graphics in a virtual machine, see *Configure 3D Graphics and Video Cards* in the *vSphere Virtual Machine Administration* documentation.

How to View Feature Capabilities Details for Your EVC Cluster

The feature set that is exposed by an EVC cluster corresponds to the feature set of a particular type of processor. Processor feature sets are described by a set of feature flags, most of which correspond to flags returned by the CPUID instruction.

You can view the feature flags currently exposed by the hosts in an EVC cluster.

1. In the vSphere Client, click the main navigation menu
   (**),**
   and select **Inventory**.
2. Select **Hosts and Clusters**.
3. Select a cluster in the inventory.
4. Click the **Configure** tab.
5. Select **VMware EVC** and expand **Current Feature Capabilities Details**.

This VMware EVC panel displays the CPUID feature flags that EVC enforces for the hosts in this cluster. For information about CPUID feature flags, see the Intel and AMD websites.

What Is vSphere Developer Center

The Developer Center is a single point of entry for developers that provides tools to manage API structure and to capture user actions to translate them into executable code.

The vSphere Client Developer Center provides tools for automation experts, devops engineers, and developers to find the resources to manage API structures and to capture vSphere Client actions to translate them into PowerCLI.

What Is vSphere API Explorer

The API Explorer allows you to browse and invoke vSphere REST APIs supported by the system and provides information and context around the API calls.

With the API Explorer, you can choose an API endpoint from your environment and retrieve a list of vSphere REST APIs. You can review details like available parameters, expected responses, and response status codes, and you can invoke the APIs against the live environment. The available APIs depend on the role of the selected endpoint.

How Do You Retrieve APIs Using vSphere API Explorer

You can use the API Explorer to retrieve available vSphere REST APIs from a selected endpoint and receive information and context around API calls.

1. In the vSphere Client, click the main navigation menu
   ( ),
   and select **Developer Center**.
2. Click the **API Explorer** tab.
3. From the **Select Endpoint** drop-down menu, select an endpoint from the environment.
4. From the **Select API** drop-down menu, select an API. The listed APIs are the ones publicly provided by the API explorer in vCenter.
5. Optional: You can use the filter text box to filter your results. For example, enter `health` to view a list of methods related to monitoring the health of the selected API.
6. Select an API category from the list.
7. Select a method from the list.

   You can review deprecated APIs by using the toggle button next to each method from the list. Avoid using deprecated APIs. Deprecated APIs might become unresponsive in the future and cause unexpected failures in your automation scripts.

   Detailed information about the method appears.
8. If a section about parameter details appears for the selected method, enter a method parameter value in the **Value** text box.
9. Optional: To invoke the method against the live environment, click **Execute**.
   a) If a warning dialog box appears, click **Yes**.

   The result for the invoked method appears in the response box.
10. Optional: To copy the result for the invoked method to your clipboard, click **Copy Response**.
11. Optional: To download the result for the invoked method, click **Download**.

What Is vSphere Code Capture

Code Capture records user actions and translates them into executable code.

Code Capture gives you the ability to record actions taken in the vSphere Client and output them as usable PowerCLI code. You can then copy the code or download it as a script and use it in a PowerShell session to execute the task.

> **Note:**
>
> Only vCenter calls are recorded. Calls made on operations regarding roles, privileges, tags, content libraries, and storage policies are not recorded.

How Do You Record Actions by Using vSphere Code Capture

After you enable Code Capture, you can use it to record a session.

To use Code Capture to record a session, you must first enable Code Capture.

You can use Code Capture to record actions taken in the vSphere Client to produce a PowerCLI code output.

> **Note:**
> Calls made on operations regarding roles, privileges, tags, content libraries, and storage policies are not recorded. Sensitive data such as passwords are not recorded.

1. In the vSphere Client, click the main navigation menu ( ), and select **Developer Center**.
2. Click the **Code Capture** tab.
3. Optional: If Code Capture is not enabled, click the toggle to enable Code Capture.
4. To start a recording, navigate to your desired pane and click the red record button in the top pane. To start recording immediately, click **Start Recording**.

   While a recording is in progress, the red record button in the top pane blinks.
5. Optional: To clear the code captured in a previous session and start a new session, click **Clear and Start Another**.
6. To stop a recording, click the red record button in the top pane, or navigate to the **Code Capture** tab in the Developer Center and click **Stop Recording**.

   The recorded code appears in the code pane.
7. Optional: Click **Copy** to copy the code or **Download** to download it as a PowerCLI script.
8. To clear the current code and start another recording, click **Clear and Start Another** or navigate to your desired pane and click the red record button in the top pane.

The recorded code appears in the code pane. You can copy the code, download it, or clear the code to start another recording.

Automating Management Tasks Using VMware Cloud Foundation Operations orchestrator

VMware Cloud Foundation Operations orchestrator is a platform that provides a library of extensible workflows. By using the workflow library, you can automate and configure processes to manage the vSphere infrastructure, other VMware technologies, and third-party technologies.

VMware Cloud Foundation Operations orchestrator exposes every operation in the vCenter API so that you can integrate all these operations into your own automated processes.

What Are VMware Cloud Foundation Operations orchestrator Workflows

A workflow is a series of actions and decisions that are automated to run sequentially after you run the workflow. VMware Cloud Foundation Operations orchestrator (VCF Operations orchestrator) provides a library of workflows that perform common management tasks.

Basics of Workflows

Workflows consist of a schema, variables, and input and output parameters. The workflow schema is the main component of a workflow as it defines all the workflow elements and the logical task flow of the workflow. The workflow variables and parameters are used by workflows to transfer data. VMware Cloud Foundation Operations orchestrator saves a workflow token every time a workflow runs, recording the details of that specific run of the workflow. This token contains all parameters related to the workflow run. For example, if you run a workflow three times, three workflow tokens are saved.

With the vSphere Client, you can run and schedule workflows on selected objects from the vSphere inventory. You cannot create, delete, edit, and manage workflows in the vSphere Client. You develop and manage workflows in the VMware Cloud Foundation Operations orchestrator client.

Input Workflow Parameters

To run, most workflows require a certain set of input parameters. The workflow processes input parameters that the user, an application, another workflow, or an action passes to it.

For example, if a workflow resets a virtual machine, the workflow requires the name of the virtual machine as an input parameter.

Output Workflow Parameters

The workflow output parameters represent the result from the workflow run. Some workflows and workflow elements can change the output parameters of the workflow when they run. While they run, workflows can receive the output parameters of other workflows as input parameters.

For example, if a workflow creates a snapshot of a virtual machine, the output parameter for the workflow is the resulting snapshot.

Workflow Input Form

When you run a workflow in the vSphere Client, the client loads the workflow presentation. You provide the input parameters of the workflow in the workflow input form.

Waiting for Input

Some workflows require user input during their run and the run is suspended either until the user provides the required information, or until the workflow run times out.

What Administration Tasks Can You Perform on vSphere Objects by Using VCF Operations orchestrator

By using VCF Operations orchestrator view in the vSphere Client, you can perform administration tasks such as running and scheduling workflows, and viewing the list of available workflows.

From the VCF Operations orchestrator view in the vSphere Client, you can work with workflows. Working with workflows includes the following tasks:

- Associating workflows with specific vSphere inventory objects such as virtual machines, ESX hosts, clusters, resource pools, and folders.
- Exporting and importing existing associations of workflows with vSphere inventory objects for backup purposes or to import them to another vCenter instance.
- Editing associations of workflows with vSphere inventory objects such as virtual machines, ESX hosts, clusters, resource pools, folders, and others.
- Viewing information about workflow runs and about workflows waiting for user intervention.
- Running and scheduling workflows on vSphere objects.

Managing Context Actions of Workflows on Your vSphere Inventory Objects

By using VCF Operations orchestrator, you can associate workflows with the different vSphere object types to see more workflows displayed in the context menu when you right-click a vSphere inventory object. You can also run these workflows on more object types.

You can add and edit context actions, and export and import configuration files containing the context actions of workflows on vSphere objects.

Workflows associated with inventory object types are listed in the context menu that appears when you right-click the inventory objects and in the **Actions** menu.

You can assign Automation Orchestrator groups. The users in the Automation Orchestrator groups and users from the VCF Operations orchestrator Administrator group in the vSphere Client can use the defined context actions on the vSphere inventory objects.

Assign an Automation Orchestrator Group in the vSphere Client

With VCF Operations orchestrator, you can assign an Automation Orchestrator group. The users in the group can use the defined context actions on the vSphere inventory objects.

- Verify that groups are created in the VMware Cloud Foundation Operations orchestrator client. For more information about VCF Operations orchestrator groups and how to create them, see the *Workload Orchestration* documentation.
- Log in to the vSphere Client as a member of the VMware Cloud Foundation Operations orchestrator Administrators group. For more information about VMware Cloud Foundation Operations orchestrator roles and groups, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.
2. Click the **Group Assignments** tab.

   A list of all groups which can use context actions is displayed.
3. Click **Assign**.
4. Select a group from the list and click **Assign**.

   The group appears in the list of assigned groups.

Associate Your Workflows with vSphere Inventory Object Types

You can associate VMware Cloud Foundation Operations orchestrator workflows with a vSphere object type, such as host, to run the workflows directly on the inventory objects of that type.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.
- Log in to the vSphere Client as a member of the VMware Cloud Foundation Operations orchestrator Administrators group. For more information about VMware Cloud Foundation Operations orchestrator roles and groups, see the *Workload Orchestration* documentation.

Workflows associated with inventory object types are listed in the context menu that appears when you right-click an inventory object, and in the **Actions** menu.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.
2. Click the **Context Actions** tab.
3. Click **Add** to add a workflow.
4. Navigate through the workflow library to find the workflow to add, and select the workflow.
5. Under Type of Object, select the vSphere object types with which you want to associate the workflow.
6. Optional: Use the add or remove icons to add or remove object types.

   To remove an object type, more than one object types must be selected.
7. Optional: Select the **Allow multiple selection** check box.

   With multi-selection enabled, you can select multiple vSphere objects of the same type when you run the workflow.
8. Click **Assign**.

   The workflow appears in the list of workflows.

Edit the Context Actions of Your Workflows on vSphere Objects

After you associate a VMware Cloud Foundation Operations orchestrator workflow with objects from the vSphere inventory, you can edit the context actions of workflows on the objects from the vSphere inventory.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.

- Log in to the vSphere Client as a member of the VMware Cloud Foundation Operations orchestrator Administrators group. For more information about VMware Cloud Foundation Operations orchestrator roles and groups, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.
2. Click the **Context Actions** tab.
3. Click the workflow that you want to edit.

   A dialog box appears.
4. Change the context action properties.
5. Click **Save**.

Export the Context Actions of Your Workflows on vSphere Objects

You can transfer the context actions of VMware Cloud Foundation Operations orchestrator workflows on objects in the vSphere inventory by using a JSON file.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.
- Log in to the vSphere Client as a member of the VMware Cloud Foundation Operations orchestrator Administrators group. For more information about VMware Cloud Foundation Operations orchestrator roles and groups, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.
2. Click the **Context Actions** tab.
3. Click **MORE** > **Export**.
4. Select a location where you want to save the JSON file, and click **Save**.

Import Context Actions of Your Workflows on vSphere Objects

You can import a JSON file that contains the context actions of VMware Cloud Foundation Operations orchestrator workflows on objects in the vSphere inventory.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.
- Log in to the vSphere Client as a member of the VMware Cloud Foundation Operations orchestrator Administrators group. For more information about VMware Cloud Foundation Operations orchestrator roles and groups, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.
2. Click the **Context Actions** tab.
3. Click **MORE** > **Import**.
4. Browse to select the JSON file to import, and click **Open**.

VMware Cloud Foundation Operations orchestrator compares the two sets of workflow context actions and imports the missing workflow context actions.

Working with VCF Operations orchestrator Workflows in the vSphere Client

In the vSphere Client, you can view information about VCF Operations orchestrator workflows, run, and schedule workflows.

You can perform some scheduling and running tasks on the VCF Operations orchestrator workflows from the VCF Operations orchestrator view in the vSphere Client.

You can schedule a workflow to run at a specified time or start a workflow directly, by right-clicking a vSphere inventory object and selecting **VCF Operations orchestrator**.

Workflow tasks include:

- Running workflows on vSphere inventory objects, such as virtual machines, ESX hosts, clusters, resource pools, and folders.
- Viewing information about workflow runs.
- Viewing information about workflows waiting for user interaction.
- Searching for a specific workflow from the list of available workflows.
- Scheduling workflows.

Run Your Workflows on vSphere Inventory Objects

You can automate management tasks in vSphere by running VCF Operations orchestrator workflows directly on objects from the vSphere inventory.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.
- Verify that you have workflows associated with the vSphere inventory objects. See Associate Your Workflows with vSphere Inventory Object Types.

1. In the vSphere Client home page, select **Global Inventory Lists** .
2. From the left navigation pane, select an inventory category.
3. Right-click the object that you want to run the workflow on, and click **VCF Operations orchestrator** > **Run Workflow**.
   A dialog box appears.
4. From the drop-down menu, select the workflow that you want to run.

   Note:
   If you cannot find the expected workflows, you might have to associate them to the specified vSphere inventory object.
5. Provide the required workflow parameters.
6. Click **Run**.

Schedule Your Workflows on vSphere Inventory Objects

You can automate management tasks in vSphere by scheduling VCF Operations orchestrator workflows directly on objects from the vSphere inventory.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.
- Verify that you have workflows associated with the vSphere inventory objects. See Associate Your Workflows with vSphere Inventory Object Types.

1. In the vSphere Client home page, select **Global Inventory Lists** .
2. From the left navigation pane, select an inventory category.
3. Right-click the object that you want to run the workflow on, and click **VCF Operations orchestrator** > **Schedule Workflow**.

   A dialog box appears.
4. In the **Task name** text box, enter the name of the scheduled task.
5. Optional: In the **Description** text box, enter a description of the scheduled task.
6. Schedule the date and time of the workflow run.
7. Optional: Specify the end date.
8. Optional: From the **Schedule** drop-down menu, select a recurrence option.
9. Click **Next**.
10. From the drop-down menu, select the workflow that you want to run.

    Note:
    If you cannot find the expected workflows, you might have to associate them to the specified vSphere inventory object.
11. Provide the required workflow parameters.
12. Click **Finish**.

Scheduling Workflows from the VCF Operations orchestrator view in the vSphere Client

From the VCF Operations orchestrator view in the vSphere Client, you can create tasks to schedule workflows, edit scheduled tasks, suspend scheduled tasks, and resume suspended scheduled tasks.

Schedule a VMware Cloud Foundation Operations orchestrator Workflow

In the vSphere Client, you can schedule a VMware Cloud Foundation Operations orchestrator workflow to run at a specified time. You can also set the recurrence for a scheduled workflow.

Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestratorplug-in for the vSphere Client, see the Workload Orchestration documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.

2. Click **Workflows**.
3. Select the workflow that you want to schedule and click **Schedule**.
4. In the **Task name** text box, enter the name of the scheduled task.
5. Optional: In the **Description** text box, enter a description of the scheduled task.
6. Schedule the date and time of the workflow run.
7. Optional: Specify the end date.
8. Optional: From the **Schedule** drop-down menu, select a recurrence option.
9. Click **Next**.
10. Provide the required workflow parameters.
11. Click **Finish**.

Edit the Schedule of Your VMware Cloud Foundation Operations orchestrator Workflow

In the vSphere Client, you can modify the schedule of a VMware Cloud Foundation Operations orchestrator workflow and set it to run at an earlier or later time.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.
2. Click **Scheduled workflows**.

   A list of the scheduled workflows appears.
3. Select the workflow whose schedule you want to edit and click **Edit**.
4. Modify the parameters of the scheduled workflow and click **Finish**.

Suspend a Scheduled VMware Cloud Foundation Operations orchestrator Workflow Run

In the vSphere Client, you can suspend a VMware Cloud Foundation Operations orchestrator scheduled task for a workflow run. You can also resume suspended scheduled tasks.

1. Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.
2. Click **Scheduled workflows**.

   A list of the scheduled workflows appears.
3. Select a workflow and click **Pause**.

   The workflow schedule is suspended.

The state of the scheduled task changes to Suspended.

Resume a Suspended Scheduled VMware Cloud Foundation Operations orchestrator Workflow Run

In the vSphere Client, you can resume a scheduled VMware Cloud Foundation Operations orchestrator workflow run that has been suspended.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.

2. Click **Scheduled workflows**.

   A list of the scheduled workflows appears.

3. Select a workflow and click **Resume**.

   The workflow schedule is resumed from suspension.

The state of the scheduled task changes to Pending.

View Information About Your VCF Operations orchestrator Workflow Runs

In the vSphere Client, you can view information about the workflow runs for the connected VCF Operations orchestrator server. The available information includes the workflow name, start and end date, state of the workflow, and the user who started the workflow.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.
- Run a VCF Operations orchestrator workflow.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.

2. Click **Workflow Runs**.

   The list of workflow runs appears.

You can review the list of workflow runs, cancel a running workflow, delete a workflow run, or respond to a workflow that requires interaction.

View Information About the Runs of a Specific Workflow

In the vSphere Client, you can view information about the runs of a single VMware Cloud Foundation Operations orchestrator workflow such as start and end date, state of the workflow, and user who has started the workflow.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.
- Run the specific VCF Operations orchestrator workflow at least once.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.

2. Click **Workflows**.

   A list of the available workflows appears.

3. Click the name of a workflow, and click the **All Runs** tab.

   A list of workflow runs appears.

You can review the list of workflow runs, cancel a running workflow, or respond to a workflow that requires interaction.

View Workflows That Are Waiting for User Input

In the vSphere Client, you can view the VMware Cloud Foundation Operations orchestrator workflows that are waiting for user input.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.

2. Click **Waiting for input**.

A list of workflows that are waiting for user input appears.
You can provide values for the required parameters of workflows that are waiting for user input. For example, the user might have to provide an approval or further details about the workflow.

Find a VCF Operations orchestrator Workflow

You can browse for workflows in the inventory of the VCF Operations orchestrator server or filter the available workflows by a search keyword to find a particular workflow. In vSphere environments with many available workflows, filtering provides a quick way to navigate through the list of workflows.

- Verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.

1. In the object navigator, click **VCF Operations Orchestrator**.

   Depending on your environment and the integration between vCenter and VMware Cloud Foundation Operations orchestrator, the name of the interface control might be **VCF Operations Orchestrator**.

2. Click **Workflows**.
3. In the filter text box, enter a search term or the name of the workflow that you want to find.

   You can see a list with the workflows that contain the search term in the workflow name or description.

Workflows for Managing Your vSphere Inventory Objects

The vCenter plug-in workflow library contains VCF Operations orchestrator workflows that you can use to run automated processes related to the vCenter and host management.

To access workflows in the vSphere Client, verify that you have configured the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client. For information about configuring the VMware Cloud Foundation Operations orchestrator plug-in for the vSphere Client, see the *Workload Orchestration* documentation.

The default workflows for managing vSphere inventory objects are the workflows included in the vCenter plug-in workflow library.

> **Note:**
> Only a predefined set of vCenter workflows are available by default in the context menu. You can associate additional workflows with each vSphere object. See Associate Your Workflows with vSphere Inventory Object Types.

For more information about the workflows available in the vCenter plug-in workflow library, see *vCenter Plug-In Workflow Library* in the *Using VMware Cloud Foundation Operations orchestrator Plug-Ins* documentation.

Working with Headless Systems

ESX supports the detection and configuration of headless systems.

A headless system is a system that can be operated without a monitor, keyboard, or mouse. Network Appliance boxes do not have Video Graphics Array (VGA), the primary interface is a single serial port. You can set up your existing headless systems to use ESX. You can add ESX appliances to a data center where virtual machines are managed with vCenter. All existing ESX features can be used with a headless system that is configured with either embedded flash or minimal local storage. ESX allows for dynamic switching between different serial modes, which is useful for diagnosing and debugging problems. You can switch between modes to view or modify system parameters.

How to Detect a Headless System

ESX automatically detects headless systems.

ESX automatically redirects the DCUI over a serial port connection to improve headless detection. When ESX automatically detects a headless system, ESX will set up the serial port as COM1, 115200 baud, and redirects the DCUI over this serial port. The specific settings of com port and baud rate are read from the Serial Port Console Redirection (SPCR) table, if it exists. This behavior can be deactivated using new boot parameters if the default settings are not acceptable. You can set the `headless` flag in the ACPI FADT table to mark a system as headless.

Serial Mode Dynamic Switching

ESX supports dynamic switching between four different serial port modes.

ESX supports serial mode dynamic switching to provide maximum platform flexibility, and to allow debugging and supportability in the text box. ESX examines the input characters for any serial port mode and switches the modes based on the input key sequence. DCUI, Shell, GDB, and Logging modes are supported. If you have two serial ports, only one of the four modes is allowed on each port. Two serial ports cannot be in the same mode. If you attempt a dynamic switch to a mode in use by the other serial port, the request is ignored. Dynamic switching eliminates the need to interrupt the boot process manually or to create a custom image to redirect to a serial port. It also addresses supportability issues regarding headless systems that only have one serial port, by making it possible to switch the serial port between different modes of operation.

What Serial Port Modes Does ESX Support

ESX supports four serial port modes — logging mode, GDB mode, Shell mode, and DCUI mode.

There are four serial port modes in ESX:

Logging mode – Logging mode is the default mode in a debug build. Logging mode sends the `vmkernel.log` over the serial port.

GDB mode – Use GDB mode for dedicated debugging.

Shell mode – Shell mode is the shell port access, which is similar to SSH.

DCUI mode – DCUI mode is a Direct Console User Interface. This is the user interface that is displayed when you boot ESX using a monitor.

> **Note:**
>
> Only COM1 and COM2 ports are supported. USB serial or PCI serial cards are not supported.

ESX Keystrokes for Dynamic Serial Mode Switching

ESX includes a unique keystroke sequence that allows dynamic serial mode switching.

Dynamic Switching Keystrokes

After the correct keystroke sequence is entered, the system switches the serial port to the desired mode.

Logging mode: `Ctrl+G, Ctrl+B, 1`

Shell mode: `Ctrl+G, Ctrl+B, 2`

DCUI mode: `Ctrl+G, Ctrl+B, 3`

GDB mode: `Ctrl+G, Ctrl+B, ?`

> **Note:**
> Once in GDB mode, you cannot switch modes again using a key sequence. You must use the CLI to switch modes.

How Do You Switch Serial Modes Through the ESX CLI

You can switch serial modes using the CLI.

Dynamic Switching Using the CLI

Use esxcfg-advcfg to set the current mode to **none**. Then set the new desired mode using the CLI.

Logging mode: `esxcfg-advcfg -s com1 /Misc/LogPort`

Shell mode: `esxcfg-advcfg -s com1 /Misc/ShellPort`

DCUI mode: `esxcfg-advcfg -s com1 /Misc/ConsolePort`

GDB mode: `esxcfg-advcfg -s com1 /Misc/GDBPort`

Example

If the serial mode is set to logging mode, enter these two commands to switch it to DCUI mode.

```
§. > esxcfg-advcfg –s none /Misc/LogPort
§. > esxcfg-advcfg –s com1 /Misc/ConsolePort
```

What Are the Keystrokes for Controlling the Serial DCUI

You can use alternate keystrokes to control the DCUI over a serial port. These alternate are useful when F2 or other function keys cannot be used.

Controlling the Serial DCUI

Alternate keystroke mappings for DCUI mode:

- Esc + 1 -> F1
- Esc + 2 -> F2
- Esc + 3 -> F3
- Esc + 4 -> F4
- Esc + 5 -> F5
- Esc + 6 -> F6
- Esc + 7 -> F7
- Esc + 8 -> F8
- Esc + 9 -> F9
- Esc + 0 -> F10
- Esc + ! -> F11
- Esc + @ -> F12

Troubleshooting Overview

The Troubleshooting section in the vCenter and Host Management documentation is a collection of common troubleshooting scenarios and solutions for problems that you might encounter when you manage vCenter and ESX hosts in a vSphere environment.

The section introduces a systematic methodology for effective troubleshooting, including how to gather diagnostic information, identify symptoms, and define the problem space before you apply fixes.

The section covers three main areas:

- **Troubleshooting with vCenter logs** — explains how to troubleshoot by using vCenter logs, which are located in the /var/log/vmware/ directory and record the activity of services and agents in your implementation. For more information, see Troubleshooting with vCenter Logs.
- **Troubleshooting vCenter and ESX host certificates** — addresses certificate-related problems, including the scenario where vCenter cannot connect to managed hosts after you replace default certificates and restart the system. For more information, see Troubleshooting vCenter and ESX Host Certificates.
- **Troubleshooting ESX hosts** — covers host-specific problems, such as resolving vSphere HA host states that indicate an error condition and can prevent vSphere HA from fully protecting the virtual machines on the host. For more information, see Troubleshooting ESX Hosts .

Guidelines for Troubleshooting Your Implementation of vSphere

To troubleshoot your implementation of vSphere, identify the symptoms of the problem, determine which of the components are affected, and test possible solutions.

Identifying Symptoms	A number of potential causes might lead to the under-performance or nonperformance of your implementation. The first step in efficient troubleshooting is to identify exactly what is going wrong.
Defining the Problem Space	After you have isolated the symptoms of the problem, you must define the problem space. Identify the software or hardware components that are affected and might be causing the problem and those components that are not involved.
Testing Possible Solutions	When you know what the symptoms of the problem are and which components are involved, test the solutions systematically until the problem is resolved.

Identifying Symptoms

Before you attempt to resolve a problem in your implementation, you must identify precisely how it is failing.

The first step in the troubleshooting process is to gather information that defines the specific symptoms of what is happening. You might ask these questions when gathering this information:

- What is the task or expected behavior that is not occurring?
- Can the affected task be divided into subtasks that you can evaluate separately?
- Is the task ending in an error? Is an error message associated with it?
- Is the task completing but in an unacceptably long time?
- Is the failure consistent or sporadic?
- What has changed recently in the software or hardware that might be related to the failure?

Defining the Problem Space

After you identify the symptoms of the problem, determine which components in your setup are affected, which components might be causing the problem, and which components are not involved.

To define the problem space in an implementation of vSphere, be aware of the components present. In addition to VMware software, consider third-party software in use and which hardware is being used with the VMware virtual hardware.

Recognizing the characteristics of the software and hardware elements and how they can impact the problem, you can explore general problems that might be causing the symptoms.

- Misconfiguration of software settings
- Failure of physical hardware
- Incompatibility of components

Break down the process and consider each piece and the likelihood of its involvement separately. For example, a case that is related to a virtual disk on local storage is probably unrelated to third-party router configuration. However, a local disk controller setting might be contributing to the problem. If a component is unrelated to the specific symptoms, you can probably eliminate it as a candidate for solution testing.

Think about what changed in the configuration recently before the problems started. Look for what is common in the problem. If several problems started at the same time, you can probably trace all the problems to the same cause.

Testing Possible Solutions

After you know the problem's symptoms and which software or hardware components are most likely involved, you can systematically test solutions until you resolve the problem.

With the information that you have gained about the symptoms and affected components, you can design tests for pinpointing and resolving the problem. These tips might make this process more effective.

- Generate ideas for as many potential solutions as you can.
- Verify that each solution determines unequivocally whether the problem is fixed. Test each potential solution but move on promptly if the fix does not resolve the problem.
- Develop and pursue a hierarchy of potential solutions based on likelihood. Systematically eliminate each potential problem from the most likely to the least likely until the symptoms disappear.
- When testing potential solutions, change only one thing at a time. If your setup works after many things are changed at once, you might not be able to discern which of those things made a difference.
- If the changes that you made for a solution do not help resolve the problem, return the implementation to its previous status. If you do not return the implementation to its previous status, new errors might be introduced.
- Find a similar implementation that is working and test it in parallel with the implementation that is not working properly. Make changes on both systems at the same time until few differences or only one difference remains between them.

Troubleshooting with vCenter Logs

You can often obtain valuable troubleshooting information by looking at the logs provided by the various services and agents that your implementation is using.

Most logs are located in `/var/log/vmware/<service_name>` for vCenter deployments.

Common Logs

The following logs are common to all vCenter deployments.

Table 102: Common Log Directories

Log Directory	Description
`../firstboot`	Stores first boot logs
`applmgmt` and `applmgmt-audit`	Stores logs related to the VMware Appliance Management Service
`cloudvm`	Stores logs for allotment and distribution of resources between services
`rhttpproxy`	Stores logs for the VMware HTTP Reverse Proxy service
`vapi`	Stores logs for the VMware vAPI Endpoint service
`vmafdd`	Stores logs for the VMware Authentication Framework - LDAP service
`vmdird`	Stores logs for the VMware Directory Service - LDAP service
`vmon`	Stores logs for the VMware Service Lifecycle Manager service

Management Node Logs

The following logs are available if a management node deployment is selected.

Table 103: Management Node Log Directories

Log Directory	Service
`rbd`	VMware vSphere Auto Deploy
`content-library`	VMware Content Library Service
`eam`	VMware ESX Agent Manager

Log Directory	Service
netdumper	VMware vSphere ESX Dump Collector
perfcharts	VMware Performance Charts Service
vmcam	VMware vSphere Authentication Proxy
vmdird	VMware Directory Service - LDAP
vmware-sps	VMware vSphere Profile-Driven Storage Service
vpxd	VMware vCenter
vpostgres	VMware Postgres service
vcha	VMware vCenter High Availability service

Troubleshooting vCenter and ESX Host Certificates

Certificates are automatically generated when you install vCenter. These default certificates are not signed by a commercial certificate authority (CA) and might not provide strong security. You can replace default vCenter certificates with certificates signed by a commercial CA. When you replace vCenter and ESX certificates, you might encounter errors.

New vCenter Certificate Does Not Appear to Load

After you replace default vCenter certificates, the new certificates might not appear to load.

When you install new vCenter certificates, you might not see the new certificate.

Existing open connections to vCenter are not forcibly closed and might still use the old certificate.

To force all connections to use the new certificate, use one of the following methods.

- Restart the network stack or network interfaces on the server.
- Restart the vCenter service.

vCenter Cannot Connect to Managed Hosts

After you replace default vCenter certificates and restart the system, vCenter might not be able to connect to managed hosts.

vCenter cannot connect to managed hosts after server certificates are replaced and the system is restarted.

Log into the host as the root user and reconnect the host to vCenter.

Troubleshooting ESX Hosts

The host troubleshooting topics provide solutions to potential problems that you might encounter when using your vCenter and ESX hosts.

Troubleshooting vSphere HA Host States

vCenter reports vSphere HA host states that indicate an error condition on the host. Such errors can prevent vSphere HA from fully protecting the virtual machines on the host and can impede vSphere HA's ability to restart virtual machines after a failure. Errors can occur when vSphere HA is being configured or unconfigured on a host or, more rarely, during normal operation. When this happens, you should determine how to resolve the error, so that vSphere HA is fully operational.

vSphere HA Agent Is in the Agent Unreachable State

The vSphere HA agent on a host is in the Agent Unreachable state for a minute or more. User intervention might be required to resolve this situation.

vSphere HA reports that an agent is in the Agent Unreachable state when the agent for the host cannot be contacted by the primary host or by vCenter. Consequently, vSphere HA is not able to monitor the virtual machines on the host and might not restart them after a failure.

A vSphere HA agent can be in the Agent Unreachable state for several reasons. This condition most often indicates that a networking problem is preventing vCenter or the primary host from contacting the agent on the host, or that all hosts in the cluster have failed. This condition can also indicate the unlikely situation that vSphere HA was deactivated and then reactivated on the cluster while vCenter could not communicate with the vSphere HA agent on the host, or that the ESX host agent on the host has failed, and the watchdog process was unable to restart it. In any of these cases, a failover event is not triggered when a host goes into the Unreachable state.

Determine if vCenter is reporting the host as not responding. If so, there is a networking problem, an ESX host agent failure, or a total cluster failure. After the condition is resolved, vSphere HA should work correctly. If not, reconfigure vSphere HA on the host. Similarly, if vCenter reports the hosts are responding but a host's state is Agent Unreachable, reconfigure vSphere HA on that host.

vSphere HA Agent is in the Uninitialized State

The vSphere HA agent on a host is in the Uninitialized state for a minute or more. User intervention might be required to resolve this situation.

vSphere HA reports that an agent is in the Uninitialized state when the agent for the host is unable to enter the run state and become the primary host or to connect to the primary host. Consequently, vSphere HA is not able to monitor the virtual machines on the host and might not restart them after a failure.

A vSphere HA agent can be in the Uninitialized state for one or more reasons. This condition most often indicates that the host does not have access to any datastores. Less frequently, this condition indicates that the host does not have access to its local datastore on which vSphere HA caches state information, the agent on the host is inaccessible, or the vSphere HA agent is unable to open required firewall ports. It is also possible that the ESX host agent has stopped.

Search the list of the host's events for recent occurrences of the event `vSphere HA Agent for the host has an error`. This event indicates the reason for the host being in the uninitialized state. If the condition exists because of a datastore problem, resolve whatever is preventing the host from accessing the affected datastores. If the ESX host agent has stopped, you must restart it. After the problem has been resolved, if the agent does not return to an operational state, reconfigure vSphere HA on the host.

> **Note:**
> If the condition exists because of a firewall problem, check if there is another service on the host that is using port 8182. If so, shut down that service, and reconfigure vSphere HA.

vSphere HA Agent is in the Initialization Error State

The vSphere HA agent on a host is in the Initialization Error state for a minute or more. User intervention is required to resolve this situation.

vSphere HA reports that an agent is in the Initialization Error state when the last attempt to configure vSphere HA for the host failed. vSphere HA does not monitor the virtual machines on such a host and might not restart them after a failure.

This condition most often indicates that vCenter was unable to connect to the host while the vSphere HA agent was being installed or configured on the host. This condition might also indicate that the installation and configuration completed, but the agent did not become a primary host or a secondary host within a timeout period. Less frequently, the condition is an indication that there is insufficient disk space on the host's local datastore to install the agent, or that there are insufficient unreserved memory resources on the host for the agent resource pool. Finally, for ESX 5.x hosts, the configuration fails if a previous installation of another component required a host reboot, but the reboot has not yet occurred.

When a Configure HA task fails, a reason for the failure is reported.

Reason for Failure	Action
Host communication errors	Resolve any communication problems with the host and retry the configuration operation.
Timeout errors	Possible causes include that the host crashed during the configuration task, the agent failed to start after being installed, or the agent was unable to initialize itself after starting up. Verify that vCenter is able to communicate with the host. If so, see vSphere HA Agent Is in the Agent Unreachable State or vSphere HA Agent is in the Uninitialized State for possible solutions.

Reason for Failure	Action
Lack of resources	Free up approximately 75MB of disk space. If the failure is due to insufficient unreserved memory, free up memory on the host by either relocating virtual machines to another host or reducing their reservations. In either case, retry the vSphere HA configuration task after resolving the problem.
Reboot pending	If an installation for a 5.0 or later host fails because a reboot is pending, reboot the host and retry the vSphere HA configuration task.

vSphere HA Agent is in the Uninitialization Error State

The vSphere HA agent on a host is in the Uninitialization Error state. User intervention is required to resolve this situation.

vSphere HA reports that an agent is in the Uninitialization Error state when vCenter is unable to unconfigure the agent on the host during the Unconfigure HA task. An agent left in this state can interfere with the operation of the cluster. For example, the agent on the host might elect itself as primary host and lock a datastore. Locking a datastore prevents the valid cluster primary host from managing the virtual machines with configuration files on that datastore.

This condition usually indicates that vCenter lost the connection to the host while the agent was being unconfigured.

Add the host back to a vCenter instance (version 5.0 or later). The host can be added as a stand-alone host or added to any cluster.

vSphere HA Agent is in the Host Failed State

The vSphere HA agent on a host is in the Host Failed state. User intervention is required to resolve the situation.

Usually, such reports indicate that a host has failed, but failure reports can sometimes be incorrect. A failed host reduces the available capacity in the cluster and, in the case of an incorrect report, prevents vSphere HA from protecting the virtual machines running on the host.

This host state is reported when the vSphere HA primary host to which vCenter is connected is unable to communicate with the host and with the heartbeat datastores that are in use for the host. Any storage failure that makes the datastores inaccessible to hosts can cause this condition if accompanied by a network failure.

Check for the noted failure conditions and resolve any that are found.

vSphere HA Agent is in the Network Partitioned State

The vSphere HA agent on a host is in the Network Partitioned state. User intervention might be required to resolve this situation.

While the virtual machines running on the host continue to be monitored by the primary hosts that are responsible for them, vSphere HA's ability to restart the virtual machines after a failure is affected. First, each primary host has access to a subset of the hosts, so less failover capacity is available to each host. Second, vSphere HA might be unable to restart an FT Secondary VM after a failure. See also *vSphere Availability* troubleshooting.

A host is reported as partitioned if both of the following conditions are met:

- The vSphere HA primary host to which vCenter is connected is unable to communicate with the host by using the management (or VMware vSAN™) network, but is able to communicate with that host by using the heartbeat datastores that have been selected for it.
- The host is not isolated.

A network partition can occur for a number of reasons including incorrect VLAN tagging, the failure of a physical NIC or switch, configuring a cluster with some hosts that use only IPv4 and others that use only IPv6, or the management networks for some hosts were moved to a different virtual switch without first putting the host into maintenance mode.

Resolve the networking problem that prevents the hosts from communicating by using the management networks.

vSphere HA Agent is in the Network Isolated State

The vSphere HA agent on a host is in the Network Isolated state. User intervention is required to resolve this situation.

When a host is in the Network Isolated state, there are two things to consider -- the isolated host and the vSphere HA agent that holds the primary role.

- On the isolated host, the vSphere HA agent applies the configured isolation response to the running VMs, determining if they should be shut down or powered off. It does this after checking whether a primary agent is able to take responsibility for each VM (by locking the VM's home datastore.) If not, the agent defers applying the isolation response for the VM and rechecks the datastore state after a short delay.
- If the vSphere HA primary agent can access one or more of the datastores, it monitors the VMs that were running on the host when it became isolated and attempts to restart any that were powered off or shut down.

A host is network isolated if both of the following conditions are met:

- Isolation addresses have been configured and the host is unable to ping them.
- The vSphere HA agent on the host is unable to access any of the agents running on the other cluster hosts.

> **Note:**
> If your vSphere HA cluster has vSAN enabled, a host is determined to be isolated if it cannot communicate with the other vSphere HA agents in the cluster and cannot reach the configured isolation addresses. Although the vSphere HA agents use the vSAN network for inter-agent communication, the default isolation address is still the gateway of the host. Hence, in the default configuration, both networks must fail for a host be declared isolated.

Resolve the networking problem that is preventing the host from pinging its isolation addresses and communicating with other hosts.

Configuration of vSphere HA on Hosts Times Out

The configuration of a vSphere HA cluster might time out on some of the hosts added to it.

When you enable vSphere HA on an existing cluster with a large number of hosts and virtual machines, the setup of vSphere HA on some of the hosts might fail.

This failure is the result of a time out occurring before the installation of vSphere HA on the host(s) completes.

Set the vCenter advanced option config.vpxd.das.electionWaitTimeSec to value=240. After this change is made, the time outs do not occur.

Authentication Token Manipulation Error

When you try to create a password that does not meet the authentication requirements of the ESX host, an error occurs.

When you create a password on the host, the following fault message appears: `A general system error occurred: passwd: Authentication token manipulation error`.

The following message is included: `Failed to set the password. It is possible that your password does not meet the complexity criteria set by the system.`

The host checks for password compliance using the default authentication plug-in, `pam_passwdqc.so`. If the password is not compliant, the error appears.

When you create a password, include a mix of characters from four character classes: lowercase letters, uppercase letters, numbers, and special characters such as an underscore or dash.

> **Note:**
> An uppercase character that begins a password does not count toward the number of character classes used. A number that ends a password does not count toward the number of character classes used.

Your user password must meet the following length requirements.

- Passwords containing characters from three character classes must be at least eight characters long.
- Passwords containing characters from all four character classes must be at least seven characters long.

When the PAM module determines if the password consists of dictionary words, the module might treat some numbers as letters and might reject a password which seems to meet the complexity requirements. For example, a password such as *P4$$w0rd* might be rejected because it is based on a dictionary word.

If the module rejects your password, you can transfer the password to the /bin/pwqcheck application on the ESX Shell, change some numbers or letters, and check if it is accepted.

For more information, see the *vSphere Security* documentation.

Managing Host and Cluster Lifecycle

Managing Host and Cluster Lifecycle provides information about configuring and using VMware®vSphere Lifecycle Manager to manage the ESX hosts and clusters in your environment.

Managing Host and Cluster Lifecycle provides instructions for configuring vSphere Lifecycle Manager, working with the vSphere Lifecycle Manager depot, and using baselines and images to install, update, or upgrade the software and firmware running on your ESX hosts.

Managing Host and Cluster Lifecycle also provides detailed guidelines about using vSphere Lifecycle Manager recommended images and performing hardware compatibility checks on single hosts or clusters. It also describes how you can configure and use the Update Manager Download Service (UMDS) to download software updates in deployments with no access to the Internet.

At VMware, we value inclusion. To foster this principle within our customer, partner, and internal community, we create content using inclusive language.

Intended Audience

This information is intended for experienced system administrators who are familiar with data center operations and virtual machine technology.

Client Interface

The instructions in this guide reflect the HTML5-based vSphere Client.

What is vSphere Lifecycle Manager

VMware vSphere Lifecycle Manager enables centralized and simplified lifecycle management for VMware ESX hosts by using images.

Lifecycle Management in vSphere

Lifecycle management refers to the process of installing software, maintaining it through updates and upgrades, and decommissioning it.

In the context of maintaining a vSphere environment, your clusters and hosts in particular, lifecycle management refers to tasks such as installing ESX and firmware on new hosts, and updating or upgrading the ESX version and firmware when required.

vSphere Lifecycle Manager Overview

vSphere Lifecycle Manager is a service that runs in vCenter. Upon deploying the vCenter appliance, the vSphere Lifecycle Manager user interface becomes automatically enabled in vSphere Client.

vSphere Lifecycle Manager encompasses the functionality that Update Manager provides in earlier vSphere releases and enhances it by adding new features and options for ESX lifecycle management at either a cluster or a standalone host at vCenter level.

In vSphere releases earlier than 7.0, Update Manager provides you with the ability to use baselines and baseline groups for host patching and host upgrade operations. Starting with vSphere 7.0, vSphere Lifecycle Manager introduces the option of using vSphere Lifecycle Manager images as the preferred way to manage the lifecycle of the hosts and clusters in your environment. You can also upgrade the virtual machine hardware and VMware Tools versions of the virtual machines in your environment.

Starting in VCF 9.1 and vSphere Foundation 9.1, vSphere Lifecycle Manager relies on the Software depot component that is part of the VCF management services. The VCF software depot centralizes the download of VMware ESX base images, vendor add-ons, components, and ESX patches and updates from Broadcom.

In air-gapped or secured networks without direct Internet access, vSphere Lifecycle Manager works with VCF software depot offline mode, the VCF download tool, or manually imported offline ZIP bundles. Direct configuration or editing of public Broadcom depot URLs in vCenter is no longer supported in vSphere 9.1 and is automatically managed by VCF software depot.

vSphere Lifecycle Manager Operations

The basic vSphere Lifecycle Manager operations are related to maintaining an environment that is up-to-date and ensuring smooth and successful updates and upgrades of the ESX hosts.

Operation	Description
Compliance Check	An operation of scanning ESX hosts to determine their level of compliance with a baseline attached to the cluster or with the image that the cluster uses. The compliance check does not alter the object.
Remediation Pre-Check	An operation that you perform before remediation to ensure that the health of a cluster is good and that no issues occur during the remediation process.
Remediation	An operation of applying software updates to the ESX hosts in a cluster. During remediation, you install software on the hosts. Remediation makes a non-compliant host compliant with the baselines attached to the cluster or with the image for cluster.
Staging	An operation that reduces the time ESX hosts spend in maintenance mode. When you stage an image or baseline to an ESX host, vSphere Lifecycle Manager downloads the respective bulletins or components from the vSphere Lifecycle Manager depot to the host without applying them immediately. Staging makes the components, patches, and extensions available locally on the hosts. You can choose to remediate the hosts at a later time, not immediately after staging.

The vSphere Lifecycle Manager Depot

Several components make up vSphere Lifecycle Manager and work together to deliver the vSphere Lifecycle Manager functionality and coordinate the major lifecycle management operations that it provides for. The vSphere Lifecycle Manager depot is an important component in the vSphere Lifecycle Manager architecture, because it contains all software updates that you use to create vSphere Lifecycle Manager images and baselines. In VCF 9.1, the vSphere Lifecycle Manager depot is populated and synchronized automatically through the VCF software depot. In addition to the VCF software depot, the vSphere Lifecycle Manager depot can consume third-party partner depots (for example, Nvidia, Mellanox), OEM partner depots (Dell, HPE, Lenovo, Cisco), and local offline ZIP bundles containing ESX patches and base images.

You can use vSphere Lifecycle Manager only if the vSphere Lifecycle Manager depot is populated with components, add-ons, base images, and legacy bulletins and patches.

For more information about software updates and how they are distributed, see Software Packaging Units That vSphere Lifecycle Manager Can Consume.

For more information about the vSphere Lifecycle Manager depot, see The vSphere Lifecycle Manager Depot.

Secure Hashing and Signature Verification in vSphere Lifecycle Manager

vCenter performs an automatic SHA-256 hash check on all software retrieved through the VCF software depot whether synchronized online, loaded from an offline VCF download tool patch store index, or imported directly as an offline ZIP bundle. The hash check verifies the SHA-256 checksum of the downloaded software to ensure its integrity. During remediation, before vSphere Lifecycle Manager installs any software on a host, the ESX host checks the signature of the installable units to verify that they are not corrupted or altered during the download.

When you import an ISO image into the vSphere Lifecycle Manager depot, vCenter performs an MD5 hash check on the ISO image to validate its MD5 checksum. During remediation, before the ISO image is installed, the ESX host verifies the signature inside the image.

If an ESX host is configured with UEFI Secure Boot, the ESX host performs full signature verification of each package that is installed on the host every time the host boots. For more information, see the *vSphere Security* documentation.

vSphere Lifecycle Manager Scalability

For information about the scalability that vSphere Lifecycle Manager supports, visit the VMware Configuration Maximums Matrix at https://configmax.broadcom.com/home.

The vSphere Lifecycle Manager User Interface in the vSphere Client

After you deploy the vCenter appliance, vSphere Lifecycle Manager becomes immediately visible in the vSphere Client.

The vSphere Lifecycle Manager user interface has two main views, which for convenience this guide calls the home view and the compliance view.

vSphere Lifecycle Manager Home View

The vSphere Lifecycle Manager home view is where you configure and administer the vSphere Lifecycle Manager instance that runs on your vCenter system. You go to the vSphere Lifecycle Manager home view to configure how vSphere Lifecycle Manager images and baselines work and to view all images used in a vCenter system.

You do not need any special privilege to access the vSphere Lifecycle Manager home view.

To access the vSphere Lifecycle Manager home view in the vSphere Client, select **Menu** > **Lifecycle Manager**.

In the vSphere Lifecycle Manager home view, you specify the vSphere Lifecycle Manager instance that you want to administer by selecting a vCenter system from the drop-down menu at the top of the **Lifecycle Manager** pane.

In the **Lifecycle Manager** pane, you have the following top-level tabs:

- If your vCenter instance is of version vSphere 9.0 and above, you have **Image Library**, **Software Depot**, **Updates**, **Baselines**, and **Settings**.
- If your vCenter instance is of version vSphere 8.0 Update 3 and earlier, you have **Software Depot**, **Updates**, **Imported ISOs**, **Baselines**, and **Settings**.

You use the **Image Library** and **Software Depot** tabs when you work with vSphere Lifecycle Manager images. You use the **Updates** and **Baselines** tabs when you work with vSphere Lifecycle Manager baselines. For more information about the **Software Depot** and **Updates** tabs, see Browsing the vSphere Lifecycle Manager Depot.

The **Settings** tab is where you configure all vSphere Lifecycle Manager remediation settings and download sources. You use the **Settings** tab with both vSphere Lifecycle Manager images and baselines. For more information about how to configure the vSphere Lifecycle Manager settings, see vSphere Lifecycle Manager Remediation Settings.

In the vSphere Lifecycle Manager home view, you can perform the following tasks:

- Browse the vSphere Lifecycle Manager depot.
- Create, import, and store vSphere Lifecycle Manager images that can be assigned to clusters and standalone hosts in the vCenter instance.
- Trigger the synchronization of updates with the configured online depots.
- Trigger the synchronization of hardware compatibility data.
- Import offline depots manually.
- Create and manage baselines and baseline groups.
- Configure the default vSphere Lifecycle Manager download source.
- Add a URL to an online depot to the list of download sources.
- Allow or disallow downloading from a download source.
- Configure host remediation settings.
- Configure virtual machine rollback settings.

vSphere Lifecycle Manager Compliance View

The vSphere Lifecycle Manager compliance view is where you perform the major vSphere Lifecycle Manager operations - checking the compliance of ESX hosts against an image or a baseline, staging, remediation pre-checks, remediation, and so on.

You go to the vSphere Lifecycle Manager compliance view to actually use the vSphere Lifecycle Manager images and baselines on your clusters and hosts.

To access the vSphere Lifecycle Manager compliance view in the vSphere Client, you must have the **View Compliance Status** privilege.

The vSphere Lifecycle Manager compliance view is on the **Updates** tab for a selected object.

Depending on the selected object, its product version, and whether you use images or baselines to manage the object, you access the vSphere Lifecycle Manager compliance view in two different ways. You create new clusters or add standalone hosts to a data center or folder only by assigning an image to these objects.

- To access the vSphere Lifecycle Manager compliance view for a cluster or a standalone host that you manage with an image, go to the **Updates** tab for the object and select **Image**.
  - If you select a vCenter instance, a data center, or a folder, in the **Images** card of the vSphere Lifecycle Manager compliance view, you can perform the following tasks:
    - Assign an image to one or many clusters or standalone hosts.
    - Check the compliance status of the ESX hosts in the cluster or the standalone host against the assigned image.
    - Run a remediation pre-check with the image associated with the cluster or the standalone host to ensure successful remediation. You can run remediation pre-checks on a single or many clusters or standalone hosts in the selected inventory object.
    - Stage an image to one or many clusters or standalone hosts to speedup the remediation process.
    - Remediate one or many clusters or standalone hosts with the image associated with them.
  - If you select a cluster or a standalone host, in the **Image** card of the vSphere Lifecycle Manager compliance view, you can perform the following tasks:
    - Export, import, and edit the image that the cluster or the standalone host are associated with.
    - Assign an image to the cluster or standalone host from the images currently available in the Image Library.
    - Upgrade the firmware of the ESX hosts in the cluster or the standalone host in case you have a hardware support manager configured.
    - Check for and view recommended images for the cluster or the standalone host.
    - Check the hardware compatibility for a selected ESX version against vSAN HCL.
    - Check the compliance status of the ESX hosts in the cluster or the standalone host against the image.
    - Run a remediation pre-check to ensure successful remediation.
    - Remediate the ESX hosts against the image that the cluster or the standalone host use.
- To access the vSphere Lifecycle Manager compliance view for a host or a cluster of ESX 8.x hosts that you manage with baselines, go to the **Updates** tab for the object and select **Baselines**.

  In the **Baselines** card of the vSphere Lifecycle Manager compliance view, you can perform the following tasks:
  - Check the compliance status of ESX hosts and clusters against baselines or baseline groups.
  - Attach and detach baselines and baseline groups to hosts and clusters.
  - Generate a remediation pre-check report that lists recommended actions to ensure successful remediation.
  - Stage patches or extensions to hosts.
  - Remediate hosts against baselines and baseline groups.
  - Remediate hosts that are part of a vSAN cluster against system-managed baselines.

On the **Updates** tab, you can also perform other tasks.

- Under **Hosts**, select **Hardware Compatibility** to check the hardware compatibility of a host against the Broadcom Compatibility Guide.
- Under **Hosts**, select **VMware Tools** or **VM Hardware** to check the status of virtual machines and upgrade the VMware Tools version or the virtual hardware version of the virtual machines.

vSphere Lifecycle Manager and vCenter Single Sign-On Domain

If your vCenter system is part of a vCenter Single Sign-On domain, you can access the settings for each vSphere Lifecycle Manager on a connected vCenter instance from a single page. Go to the vSphere Lifecycle Manager home view and from the **Lifecycle Manager** drop-down menu select a vCenter instance. The individual vSphere Lifecycle Manager instances do not share settings or objects and must be configured independently.

Using vSphere Lifecycle Manager with VMware vSphere®Distributed Services Engine™

vSphere Distributed Services Engine provides you with the ability to offload some of the network operations from your server CPU to a data processing unit, or the so-called DPU device on the server. You can use vSphere Lifecycle Manager images and all vSphere Lifecycle Manager operations to manage the life cycle of the software and firmware that runs on the DPU devices of your servers.

Using DPU devices for network acceleration frees up the CPU capacity for business-critical workloads. Besides accelerating networking performance, using DPU devices provides security and compression acceleration.

What Is a DPU Device?

A DPU device is a high-performance network interface card, with added embedded CPU cores, memory, and a hypervisor running on the device independently from the ESX hypervisor installed on the server. DPU devices are like limited-resource servers with multiple general-purpose compute cores.

The ESX hypervisor that runs on the DPU device is a fully functional hypervisor, but it can only run on ARM CPU architectures. You do not use ESX on the DPU to run and provision virtual machines and workloads. The hypervisor that runs on DPU devices is a trimmed version of the ESX hypervisor that runs on your servers. This trimmed ESX version is optimized for I/O activities, such as packet offloads, external management, and so on.

From vSphere perspective, the DPU device is a pre-configured device that you can start using without any further configuration or customizations.

You cannot manage DPU devices separately from managing your ESX hosts. All lifecycle operations that you use to manage the lifecycle of the software and firmware on your hosts are used to also manage the software and firmware lifecycle of DPU devices in a DPU-based environment.

The DPU devices that VCF 9.1 supports are from NVIDIA and AMD, and server designs from Dell, HPE, Lenovo, and Fujitsu.

How Do I Start Using a Server with a DPU Device?

To take advantage of the vSphere Distributed Services Engine, your server must include a supported DPU device. You cannot purchase a DPU device separately and insert it into a legacy non-DPU server.

To start utilizing the DPU device on a server to offload network services, you must perform a fresh ESX installation on the server. During installation, ESX is installed both on the server and on the DPU device. The ESX image contains VIBs for both the ESX version to be installed on a host and the ESX version to be installed on the DPU device on that host.

Managing the Lifecycle of the ESX and Firmware on a DPU Device

You use vSphere Lifecycle Manager to upgrade the ESX version and firmware on a DPU device. The VIBs that are needed to upgrade the DPU device are included in the base ESX images that VMware distributes and that you have in the vSphere Lifecycle Manager depot. You do not need to take care of the software and firmware on a DPU device separately. For example, during remediation vSphere Lifecycle Manager updates ESX both on the host and on the DPU device.

You can have a vSphere Distributed Services Engine installation with 2 DPUs, see High Availability with VMware vSphere Distributed Services Engine. vSphere Lifecycle Manager operations happen in parallel on both DPU devices for hosts with dual DPU setup.

vSphere Lifecycle Manager operations are compatible with DPU-based environments. However, keep the following operations in mind:

- Recommendation generation

- Hardware compatibility checks work only if the cluster does not contain a mix of DPU and non-DPU enabled hosts.

Solutions Interoperability with vSphere Distributed Services Engine

NSX is the only solution that is allowed to push VIBs to ESX on the server, on the DPU, or both. Currently, no other solutions can work together with the vSphere Distributed Services Engine.

System Requirements for Using vSphere Distributed Services Engine

- ESX 8.0 or later
- vCenter 8.0 or later

Limitations to Using vSphere Lifecycle Manager for a DPU-Backed Cluster

- The vSphere Distributed Services Engine works for clusters and standalone hosts that you manage with a vSphere Lifecycle Manager image. You cannot add a host with a DPU device to a cluster that you manage with baselines.
- A host can have one or two DPU devices. If a host has two DPU devices, they must run the same firmware and hardware revisions.
- Each host in the DPU-based cluster must have a DPU device.
- All hosts must have DPU devices from the same vendor and of the same model. The DPU generation might vary.

Software Packaging Units That vSphere Lifecycle Manager Can Consume

VMware and other software vendors create and package their software updates into specific units that vSphere Lifecycle Manager can consume. The smallest packaging construct is the component. Components can be further grouped into larger software units, such as add-ons and base images.

vSphere Lifecycle Manager uses software from VMware, original equipment manufacturers (OEMs), and third-party software providers.

- OEMs are VMware partners, such as, Dell, HPE, Lenovo.
- Third-party software providers are providers of I/O filters, device drivers, CIM modules, and so on.

What Is a vSphere Installation Bundle (VIB)?

The VIB is the basic building block for the creation of installation packages for ESX hosts. A VIB is a software package that contains metadata and a binary payload, which represents the actual piece of software to be installed on an ESX host. The VIB does not represent an entire feature, but just a single module of the feature. So, the VIB is the smallest installable software unit that VMware and other software vendors ship.

A VIB can install software on either the ESX running on the host or the ESX running on a DPU device on the host. Alternatively, a single VIB can carry updates for both the ESX versions on the host and on the DPU device.

Table 104: VIB Terminology

Term	Definition
VIB Metadata	An XML file (`descriptor.xml`) that describes the contents of the VIB. It also contains dependency information, textual descriptions, system requirements, and information about bulletins.
Standalone VIB	A VIB that is not included in a bulletin or component.

vSphere Lifecycle Manager does not consume and work with individual VIBs. VIBs must be further packaged into a higher-level construct, such as a base image, an add-on, and so on.

What Is a Bulletin?

The bulletin is a grouping of one or more VIBs. Bulletins are defined within the metadata of the VIB. You use bulletins, and not individual VIBs, to create vSphere Lifecycle Manager baselines, which you attach to inventory objects and use to update and upgrade ESX hosts.

Table 105: Bulletin Terminology

Term	Definition
Patch	A small software update that provides bug fixes or enhancements to the current version of the software. A patch groups one or more VIBs together to address a particular issue or to provide enhancements to the current version of the software.
Roll-up Bulletin	A collection of patches that are grouped to facilitate downloads and deployment.
Extension	A bulletin that defines a group of VIBs for adding an optional component to an ESX host. An extension is usually provided by a third party. The third-party provider is also responsible for providing patches and updates for the extension.

What Are Software Components?

The component is the basic packaging construct for VIBs. VMware, OEMs, and third-party software providers deliver software in the form of components. The component is a bulletin with additional metadata specifying the name and the version of the component. Unlike the bulletin, the component is a logical grouping of VIBs that provides you with a complete and visible feature upon installation. Components can contain VIBs for the ESX version on the server, ESX version the DPU device of the server, if the server is DPU-backed, or for both of them.

VMware and OEMs do not deliver components independently. VMware bundles components together into fully functional and bootable ESX base images. OEMs bundle components together into vendor add-ons. Third-party software vendors create and ship software, for example, drivers or adapters, as independent components.

What Is a Base Image?

The base image is an ESX image that VMware provides with every release of ESX. Base images are not provided by the original equipment manufacturers (OEMs).

The base image is a collection of components that is complete and cannot be modified. The base image is the immutable base building block of the vSphere Lifecycle Manager image. It can boot up a server.

Base images have a user-readable name and a unique version that is updated with every major or minor release of ESX.

The version of a base image corresponds to an ESX release and uses the following naming format:

Release Type	Base Image Naming Example
General Availablity release	ESX 9.0.0.0, ESX 9.1.0.0, ESX 8.0
Update release	ESX 9.0.1.0, ESX 9.0.2.0, ESX 8.0 U1, ESX 8.0 U2, and so on
Patch release	ESX 9.0.1.0100, ESX 9.0.1.0200, ESX 8.0a, ESX 8.0sa, and so on

Base images can contain components and VIBs applicable to the ESX version running on a DPU device. So, a single base image can contain software updates for both ESX on the server and ESX on the DPU device.

Base images are hosted and available in the VMware online depot. Additionally, you can download an ESX installer ISO file and an offline bundle (ZIP file) that contains the ESX version from the Broadcom Support Portal.

What Is a Vendor Add-On?

OEMs pack one or multiple components into a unit called an add-on. You use vendor add-ons to customize an ESX image with OEM content and drivers.

The add-on is a collection of components that does not represent a complete, bootable image. You cannot use vendor add-ons on their own. To customize an ESX release, you must add the vendor add-on to an ESX base image. The combination of a vendor add-on and an ESX base image is practically identical to the custom image that OEMs provide.

When combined with an ESX base image, the add-on can add, update, or remove components that are part of the ESX base image. In vSphere Client, for each add-on available in the depot, you can view the list of components that it adds to an ESX base image. Similarly, you can find information about the components that it removes from a base image.

In addition to custom ISO images used only for baselines and offline bundles, OEMs release ZIP files that contain only the vendor add-on - the delta between the custom image and the ESX base image. OEMs can release such add-on ZIP files at their discretion. The introduction of the concept of add-ons decouples the release cycle of OEMs from the release cycle of VMware. As a result, you can update vendor add-ons independently of updating the ESX version of your hosts. Also, the vendor add-on decouples the OEM customization from the VMware stock image. As a result, you can combine software components more freely.

Vendor add-ons support the ESX software that runs on DPU devices.

Components and Bulletins in the vSphere Lifecycle Manager Depot

vSphere Lifecycle Manager can consume both components and bulletins.

If you use vSphere Lifecycle Manager images to manage hosts and clusters, you can only work with components and the related notions of add-ons and base images. You can find the list of the components, add-ons, and ESX base images on the **Software Depot** tab in the vSphere Lifecycle Manager home view.

If you use baselines and baseline groups to update hosts and clusters, vSphere Lifecycle Manager reads and lists the software updates that are available in the vSphere Lifecycle Manager depot as bulletins. You can find the list of available bulletins on the **Updates** tab in the vSphere Lifecycle Manager home view.

vSphere Lifecycle Manager Images and Baselines

vSphere Lifecycle Manager enables you to manage ESX hosts and clusters with images.

vSphere Lifecycle Manager images and vSphere Lifecycle Manager baselines are different in their essence, the way they work, and the features they support.

> **Important:**
>
> Starting with vSphere 9.0, upgrading to the latest version of ESX is only possible using vSphere Lifecycle Manager images. Baseline support was deprecated in vSphere 8.0 and removed in 9.0. For more information, see KB 379388.

You use vSphere Lifecycle Manager images to perform the following tasks.

- Install a desired ESX version on all hosts in a cluster or on a standalone host.
- Install and update third-party software on all ESX hosts in a cluster or on a standalone host.
- Update and upgrade the ESX version on all hosts in a cluster or on a standalone host.
- Update the firmware of all ESX hosts in a cluster or of a standalone host.
- Generate recommendations and use a recommended image for your cluster or host.
- Check the hardware compatibility of hosts and clusters against the VMware Compatibility Guide and the vSAN Hardware Compatibility List.

In vSphere 9.x, you use vSphere Lifecycle Manager baselines and baseline groups to perform only the following tasks.

- Update and patch ESX hosts only of version 8.x.
- Update third-party software on ESX hosts.

vSphere Lifecycle Manager Images

You use vSphere Lifecycle Manager images to apply software and firmware updates to the ESX hosts in a cluster. Using an image to manage all hosts in a cluster ensures a consistent, declarative state.

You can use various methods and tools to deploy ESX hosts and maintain their software lifecycle. For example, you can upgrade hosts by using vSphere Image Builder, ESXCLI, vSphere Auto Deploy. The different deployment and upgrade choices involve different workflows and require you to use different ESX image formats. When you use vSphere Lifecycle Manager images, you follow one workflow and use the same ESX image format for all software lifecycle-related operations: install, upgrade, update, and patching, which significantly simplifies the lifecycle management process.

Understanding vSphere Lifecycle Manager Images

A vSphere Lifecycle Manager image represents a desired software specification to be applied to the hosts in a cluster. When you set up a vSphere Lifecycle Manager image, you can define the full software stack that you want to run on the hosts in a cluster: the ESX version, additional VMware software, vendor and third-party software, for example, firmware and drivers.

A vSphere Lifecycle Manager image can consist of the following four elements:

- ESX base image
  The base image contains an image of VMware ESX Server and additional components, such as drivers and adapters that are necessary to boot a server. The base image is the only mandatory element in a vSphere Lifecycle Manager image. All other elements are optional.
- Vendor add-on
  The vendor add-on is a collection of software components that OEMs create and distribute. The vendor add-on can contain drivers, patches, and solutions.
- Firmware and drivers add-on
  The firmware and drivers add-on is a special type of vendor add-on designed to assist in the firmware update process. The firmware and drivers add-on contains firmware for a specific server type and corresponding drivers. To add a firmware and drivers add-on to your image, you must install the hardware support manager plug-in provided by the hardware vendor for the hosts in the respective cluster.
- Independent components
  The component is the smallest discrete unit in an image. The independent components that you add to an image contain third-party software, for example drivers or adapters.

You can set up a composite image on a cluster that has hosts from different vendors or from the same vendor but different generations, family, or model. A composite image contains one default image and one or many alternative images. All images in a composite image contain the same base image and solutions but may require different vendor or firmware and driver add-ons.

You must set up or assign a vSphere Lifecycle Manager image for a cluster during the creation of the cluster or the addition of the standalone host to the data center or folder.

> **Note:**
>
> If you switch to using images, you cannot revert to using baselines for that cluster or standalone host. If you move a host out of a cluster managed with an image, the lifecycle of the standalone host is now managed by the image which is derived from the cluster's image. You cannot add this host to a cluster managed with baselines.

The Desired State Model

The concept of images that vSphere Lifecycle Manager introduces is based on the Desired State model for managing ESX hosts and clusters.

The desired state of an ESX host represents both the target software and target configuration for the host as opposed to the software and configuration that it currently runs. The Desired State model is the idea of managing hosts and clusters by defining and applying a desired state instead of listing and following steps to change the current state.

vSphere Lifecycle Manager Baselines and Baseline Groups

You can use baselines and baseline groups only to update or patch the ESX hosts of version 8.x in your environment. You must use images to update and upgrade the hosts of version vSphere 8.0 and later in your environment.

Note:

Upgrading to the latest version of ESX is only possible by using vSphere Lifecycle Manager images. Baseline support was deprecated in vSphere 8.0 and removed in 9.0 and later. For more information, see Broadcom knowledge base article 379388.

If you still have clusters or standalone hosts that use baselines, you must transition them to clusters and standalone hosts that use images to be able to upgrade to ESX version 9.0 and later. See Transition a Cluster or a Host That Uses Baselines Into a Cluster or a Host That Uses Images.

Baselines

A baseline is a grouping of multiple bulletins. You can attach a baseline to an ESX host and check the compliance of the host against the associated baseline.

Baselines can be classified according to different criteria.

- Depending on the type of content, baselines are patch baselines and extension baselines. Patch and extension baselines contain bulletins of the respective kind.
- Depending on how the update content is selected, baselines are fixed and dynamic.
- Depending on how they are created and managed, baselines are predefined, recommendation, or custom baselines.

Baseline Groups

A baseline group is a collection of non-conflicting baselines. You can attach the entire baseline group to an inventory object to check the compliance status of the object against all the baselines in the group as a whole.

You can combine custom baselines with any of the predefined baselines to create baseline groups.

Host baseline groups can contain various patch and extension baselines.

To update ESX hosts by using baselines or baseline groups, you must first attach the baselines or baselines group to an inventory object.

Although you can attach baselines and baseline groups to individual objects, a more efficient method is to attach them to container objects, such as folders, vApps, clusters, and data centers. Individual vSphere objects inherit baselines attached to the parent container object. Removing an object from a container removes the inherited baselines from the object.

For more information about creating and managing baselines and baseline groups, see Types of vSphere Lifecycle Manager Baselines and Baseline Groups.

What Is the Difference Between vSphere Lifecycle Manager Images and Baselines

A vSphere Lifecycle Manager image is a combination of components, vendor add-on, and an ESX base image. A vSphere Lifecycle Manager baseline is a collection of bulletins. Some differences exist between the operations that you can perform on clusters that you manage with a vSphere Lifecycle Manager image and the operations on clusters that you manage with vSphere Lifecycle Manager baselines.

Operation	Images	Baselines
Distribution	Base image, vendor add-ons, and components are distributed through online depots and as offline bundles.	Bulletins are distributed through online depots and as offline bundles.
Validation	Supported. You can validate a vSphere Lifecycle Manager image to check if it is applicable to all hosts in the cluster. You can also perform a remediation pre-check.	Not supported. You do not validate a baseline before applying the updates to the hosts. You can only perform a remediation pre-check.

Operation	Images	Baselines
Import/Export	You can export an image and can use it to manage other clusters in the same or in a different vCenter instance. Images are portable across vCenter instances. You can export an image as an ISO, ZIP, or JSON file, but you can only import images that are in a JSON format when you create an image or add an image to Image Library.	You can create a custom baseline and can attach it to different objects in the same vCenter instance. You cannot export baselines and cannot distribute them across vCenter instances.
Compliance checks	With vSphere Lifecycle Manager images, you can check the compliance of the hosts against an image. To check the compliance against another image, you can use an image from the Image Library or set up a new image.	With baselines, you can check the compliance of an object against a single or against multiple baselines.
Staging	Supported. You can stage an image to a cluster or a host in the cluster before remediation. Staging reduces ESX downtime.	Supported. You can stage updates to the hosts before actually installing them.
Remediation	With vSphere Lifecycle Manager images, you can add, remove, or modify the components in the image that you use for a cluster. When you remediate the hosts against the new image, all modified components are applied to the host. So, you can upgrade and patch a host with a single remediation operation. vSphere Lifecycle Manager images define the precise image to be applied to the hosts after remediation. No deviation from the defined image is possible after remediation. vSphere Lifecycle Manager does not allow solutions to push VIBs to the hosts.	With vSphere Lifecycle Manager baselines, you can remediate an object against a single baseline or against multiple baselines. So, with a single operation, you can patch and update a host. However, vSphere Lifecycle Manager baselines list the updates to be applied to hosts, but the remediation result is not always predictable, because ESX image on the hosts might change after remediation.
Firmware updates	Supported. With vSphere Lifecycle Manager images, firmware updates are carried out through firmware and drivers add-ons, which you add to the image that you use to manage a cluster. Updating firmware with images requires an OEM-provided hardware support manager (HSM) plug-in, which integrates with vSphere Lifecycle Manager. **Note:** In VCF 9.1, vSphere Lifecycle Manager validates the currently installed firmware version for a given device against the vSAN HCL when you do not configure a hardware support manager. This check ensures that the current firmware remains compatible after the upgrade since the system does not update firmware during this process. Both vCenter and ESX must run version 9.1 or later to generate this hardware compatibility report for homogeneous or heterogeneous clusters.	Not supported.
Hardware compatibility checks	Supported You can check the hardware compatibility of the hosts in a cluster against the Broadcom Compatibility Guide (BCG). You can also check the compatibility of all hosts in a vSAN-enabled cluster against the vSAN Hardware Compatibility List (vSAN HCL).	Not supported.
Software recommendations	Supported. Based on the hardware of the hosts in the cluster, you get recommendations about available and applicable ESX updates or upgrades.	Limited support. Software recommendations are only available for vSAN clusters in the form of recommendation baselines.
vCenter /Data center-level operations	With vSphere Lifecycle Manager images, you can trigger all main image operations at a vCenter or data center level.	With vSphere Lifecycle Manager baselines, you can trigger any of the main operations at the vCenter or data center level.

Operation	Images	Baselines
Virtual machine management	You can upgrade the VMware Tools and virtual hardware versions of the virtual machines in a cluster that you manage with vSphere Lifecycle Manager images.	Supported.
VCF Download Tool	Supported.	Not supported.
Remote Office/Branch Offices (ROBO) support	Supported. With vSphere Lifecycle Manager images, use VCF software depot to manage and distribute software depots centrally across remote locations. If a specific remote cluster requires an alternate local HTTP mirror outside of VCF software depot, you can optionally configure a depot override. For more information, see Manage Depot Overrides for a Cluster or a Standalone Host.	Not supported. Although no specific optimization exists for ROBO deployments, you can still use baselines and baseline groups with ROBO clusters.
REST APIs	Available.	Not available.
Support for DPU devices	Supported. To manage a cluster of DPU-backed hosts, you can only use vSphere Lifecycle Manager images. All vSphere Lifecycle Manager operations that work for updating the ESX version on the host also deliver updates to the ESX version on the DPU device on the host.	Not supported. You cannot use baselines for clusters that contain hosts with DPU devices.
ESX Live Patching	Supported. To deploy patches with resolved security and functional issues to all ESX hosts in a cluster managed with an image with minimal disruption to your workloads. See Configuring for Live Patches.	Not supported.

What Are the Requirements for Using vSphere Lifecycle Manager

You must comply with a set of requirements to use images for software lifecycle management. To achieve your goals, you must also know the specifics in behavior and limitations that vSphere Lifecycle Manager has.

Important:

Upgrading to the latest version of ESX is only possible using vSphere Lifecycle Manager images. Baseline support was deprecated in vSphere 8.0 and removed in 9.0. For more information, see KB 379388.

Table 106: Requirements for Using vSphere Lifecycle Manager

Scenario	Requirements
Using an image to manage a cluster.	• All ESX hosts in the cluster must be of version 8.0 and later. • All ESX hosts in the cluster must be stateful. A stateful installation is one in which the host boots from a disk or from a vCenter-level UEFI HTTP(s) boot URL by using Zero Touch Provisioning. **Note:** In a vCenter instance of version 9.0 and later, you can assign vSphere Lifecycle Manager images to clusters with stateless hosts and standalone stateless hosts but only in specific cases. See Managing Stateless Hosts with an Image. • ESX hosts in the cluster can be from different vendors or from the same vendor but different generations or models. Different generations and models of servers may need different software drivers. When a vendor requires different VIBs for different models, you must set up a composite image to manage each generation or model. In vSphere 9.0 and later, you can use a composite vSphere Lifecycle Manager image to manage a heterogeneous cluster that has hosts from different vendors. You can remediate a cluster with a single or composite image depending on the homogeneity of the hosts in the cluster. vSphere Lifecycle Manager does not detect the hardware differences between the hosts in the cluster so you need to match the alternative images with the hosts on which you want them to be applied. • If you want to use DPU devices for network acceleration, all hosts in the cluster must have a DPU device from the same vendor and of the same model. You cannot add a host without a DPU device to a cluster of DPU-backed hosts. • The cluster must include only integrated components. For example: – VMware vSAN™ – VMware vSphere® High Availability (HA) – vSphere IaaS Control Plane – NSX
Using an image to manage a standalone host.	• The standalone ESX host must be of version 8.0 and later. • The standalone ESX host must be stateful. A stateful installation is one in which the host boots from a disk or a vCenter-level UEFI HTTP(s) boot URL (using Zero Touch Provisioning). vSphere Lifecycle Manager images can be assigned to standalone stateless hosts of version 9.0 and later but only in very specific cases. See Managing Stateless Hosts with an Image. • You manage the lifecycle of a standalone host only using a single image. • The host must include only integrated solutions. For example, the witness host for a vSAN stretch cluster must be a standalone host. For more information, see the *vSAN Planning and Deployment* documentation and vSAN Clusters and vSphere Lifecycle Manager.

Scenario	Requirements
Using baselines and baseline groups to update a cluster or a host.	• To use baselines for ESX host patching operations, vSphere Lifecycle Manager works only with ESX hosts of version 8.x. • vCenter 9.0 and later does not support baselines for ESX host upgrade operations.
Switching from using baselines to using an image to manage a cluster or a host.	• The cluster or the standalone host must meet the requirements for using an image. • The cluster or the standalone host must be eligible for the transition. For more information about the **Check cluster's eligibility to be managed with an image** and **Check host's eligibility to be managed with an image** tasks, see Cluster or Standalone Host Eligibility to Use vSphere Lifecycle Manager Images.
Upgrading virtual machine hardware and VMware Tools	For VMware Tools and virtual machine hardware upgrade operations, vSphere Lifecycle Manager works with ESX 9.x.

Required Privileges for Using vSphere Lifecycle Manager

To configure vSphere Lifecycle Manager settings and to use successfully vSphere Lifecycle Manager images and baselines, you must have the proper privileges.

You can assign vSphere Lifecycle Manager privileges to different roles in vSphere Client.

vSphere Lifecycle Manager Privileges For Using Images

When you use vSphere Lifecycle Manager images, you need a different set of privileges for each task.

Table 107: vSphere Lifecycle Manager Privileges For Using Images

Task	Privilege in vSphere Client	Privilege in the API
Set Up an Image	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Write** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read**	• `VcIntegrity.lifecycleSoftwareSpecification.Read` • `VcIntegrity.lifecycleSoftwareSpecification.Write` • `VcIntegrity.lifecycleSettings.Read`
Import an Image	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Write** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read** • **VMware vSphere Lifecycle Manager > Upload File > Upload upgrade images and offline bundles**	• `VcIntegrity.lifecycleSoftwareSpecification.Read` • `VcIntegrity.lifecycleSoftwareSpecification.Write` • `VcIntegrity.lifecycleSettings.Read` • `VcIntegrity.FileUpload.com.vmware.vcIntegrity.ImportFile`
Export an Image	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Read**	• `VcIntegrity.lifecycleSoftwareSpecification.Read`

Task	Privilege in vSphere Client	Privilege in the API
Edit an Image	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Write** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read**	• `VcIntegrity.lifecycleSoftwareSpecification.Read` • `VcIntegrity.lifecycleSoftwareSpecification.Write` • `VcIntegrity.lifecycleSettings.Read`
Work with Recommendations	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Write** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read**	• `VcIntegrity.lifecycleSoftwareSpecification.Read` • `VcIntegrity.lifecycleSoftwareSpecification.Write` • `VcIntegrity.lifecycleSettings.Read`
Work with Depots	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Write**	• `VcIntegrity.lifecycleSoftwareSpecification.Read` • `VcIntegrity.lifecycleSoftwareSpecification.Write`
Manage Depot Overrides	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Write**	• `VcIntegrity.lifecycleSoftwareSpecification.Read` • `VcIntegrity.lifecycleSoftwareSpecification.Write`
Check Compliance	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Read**	• `VcIntegrity.lifecycleSoftwareSpecification.Read`
Run Remediation Pre-Check	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: General Privileges > Read** • **VMware vSphere Lifecycle Manager > ESXi Health Perspectives > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Remediation Privileges > Read**	• `VcIntegrity.lifecycleGeneral.Read` • `VcIntegrity.lifecycleHealth.Read` • `VcIntegrity.lifecycleSoftwareRemediation.Read`
Remediate Against an Image	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: General Privileges > Read** • **VMware vSphere Lifecycle Manager > ESXi Health Perspectives > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Remediation Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Remediation Privileges > Write** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read**	• `VcIntegrity.lifecycleGeneral.Read` • `VcIntegrity.lifecycleHealth.Read` • `VcIntegrity.lifecycleSoftwareRemediation.Read` • `VcIntegrity.lifecycleSoftwareRemediation.Write` • `VcIntegrity.lifecycleSettings.Read`

Task	Privilege in vSphere Client	Privilege in the API
Edit Remediation Settings	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Write**	• `VcIntegrity.lifecycleSettings.Read` • `VcIntegrity.lifecycleSettings.Write`
Update Firmware	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Read** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Privileges > Write** • **VMware vSphere Lifecycle Manager > Lifecycle Manager: Settings Privileges > Read**	• `VcIntegrity.lifecycleSoftwareSpecification.Read` • `VcIntegrity.lifecycleSoftwareSpecification.Write` • `VcIntegrity.lifecycleSettings.Write`
View Hardware Compatibility	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Hardware Compatibility Privileges > Access Hardware Compatibility**	• `VcIntegrity.HardwareCompatibility.Read`
Stage an Image	• **VMware vSphere Lifecycle Manager > Lifecycle Manager: Image Remediation Privileges > Write**	• `VcIntegrity.lifecycleSoftwareRemediation.Write`

For more information about managing users, groups, roles, and permissions, see the *vSphere Security* documentation.

vSphere Lifecycle Manager Privileges For Using Baselines

Each of the vSphere Lifecycle Manager privileges that you need to use baselines and baseline groups covers a distinct functionality.

Table 108: VMware vSphere Lifecycle Manager Privileges For Using Baselines

Task	Privilege in vSphere Client	Privilege in the API	Description
Configure	**VMware vSphere Lifecycle Manager > Configure > Configure Service**	`VcIntegrity.General.com.vmware.vcIntegrity.Configure`	Configure the vSphere Lifecycle Manager service and the scheduled patch download task.
Manage Baseline	**VMware vSphere Lifecycle Manager > Manage Baselines > Attach Baseline**	`VcIntegrity.Baseline.com.vmware.vcIntegrity.AssignBaselines`	Attach baselines and baseline groups to objects in the vSphere inventory.
	VMware vSphere Lifecycle Manager > Manage Baselines > Manage Baselines	`VcIntegrity.Baseline.com.vmware.vcIntegrity.ManageBaselines`	Create, edit, or delete baselines and baseline groups.
Manage Patches and Upgrades	**Manage Patches and Upgrades > Remediate to Apply Patches, Extensions, and Upgrades**	`VcIntegrity.Updates.com.vmware.vcIntegrity.Remediate`	Remediate virtual machines and hosts to apply patches, extensions, or upgrades. In addition, this privilege allows you to view the compliance status of objects.

Task	Privilege in vSphere Client	Privilege in the API	Description
	VMware vSphere Lifecycle Manager > **Manage Patches and Upgrades** > **Scan for Applicable Patches, Extensions, and Upgrades**	`VcIntegrity.Updates.com.vmware.vcIntegrity.Scan`	Scan virtual machines and hosts to search for applicable patches, extensions, or upgrades.
	VMware vSphere Lifecycle Manager > **Manage Patches and Upgrades** > **Stage Patches and Extensions**	`VcIntegrity.Updates.com.vmware.vcIntegrity.Stage`	Stage patches or extensions to hosts. In addition, this privilege allows you to view the compliance status of hosts.
	VMware vSphere Lifecycle Manager > **Manage Patches and Upgrades** > **View Compliance Status**	`VcIntegrity.Updates.com.vmware.vcIntegrity.ViewStatus`	View baseline compliance information for an object in the vSphere inventory.
Upload File	**VMware vSphere Lifecycle Manager** > **Upload File** > **Upload upgrade images and offline bundles**	`VcIntegrity.FileUpload.com.vmware.vcIntegrity.ImportFile`	Upload upgrade images and offline patch bundles.

For more information about managing users, groups, roles, and permissions, see the *vSphere Security* documentation.

The vSphere Lifecycle Manager Depot

The vSphere Lifecycle Manager depot is the source of software updates for vSphere Lifecycle Manager. Starting in VMware Cloud Foundation 9.1 and VMware vSphere Foundation 9.1, vCenter populates the depot through the integrated VCF software depot, replacing direct depot URL configuration.

The vSphere Lifecycle Manager depot is a local depot on the vCenter appliance. This local depot contains software updates that vSphere Lifecycle Manager downloads through the VCF software depot. You can also manually import updates into the vSphere Lifecycle Manager depot.

vSphere Lifecycle Manager manages software updates exclusively for VMware ESX hosts, including ESX base images, vendor add-ons, I/O device drivers (VIBs), async VMware Tools, and host patches. You can work with vSphere Lifecycle Manager only if the vSphere Lifecycle Manager depot contains software packages.

On March 31, 2025, Broadcom transitioned to a unified software depot (`dl.broadcom.com`) for all VCF and vSphere Foundation binaries. Access to this depot is managed centrally by the VCF software depot rather than by customer-specific token URLs configured directly in vSphere Lifecycle Manager.

Starting in VCF 9.1 and vSphere Foundation 9.1, the vSphere Lifecycle Manager depot authentication and synchronization are delegated to the VCF software depot, which runs in VCF Operations. Direct customer token URLs configured in vCenter are deprecated and replaced by centralized activation codes (see Broadcom knowledge base article 443647) in VCF Operations. UMDS is officially deprecated in 9.1 and replaced by the VCF software depot for online synchronization and the VCF download tool (VCFDT) for offline patch store generation.

In environments without access to the Internet, you can use the VCF download tool for downloading software from the Broadcom online depot and configure an offline depot (web server) for storing the downloads. Alternatively, you can use offline depots (offline bundles) to import updates into the vSphere Lifecycle Manager depot manually.

How Do Software Updates Reach the vSphere Lifecycle Manager Depot

In vSphere 9.1, vSphere Lifecycle Manager no longer connects directly to the Broadcom online depot. Instead, vCenter populates the depot through the integrated VCF software depot. The VCF software depot handles authorization with `dl.broadcom.com` by using activation codes that are configured in VCF Operations, and retrieves ESX metadata, VIBs, and compatibility bundles into the vSphere Lifecycle Manager depot.

When VCF software depot is registered, vSphere Lifecycle Manager automatically configures the service as the depot source and removes legacy direct Broadcom URLs. Administrators manage depot activation codes in VCF Operations,

not in vSphere Lifecycle Manager. Manually editing Broadcom depot URLs in vSphere Lifecycle Manager is not supported and can disrupt the VCF software depot integration.

For information about activation codes, see Broadcom knowledge base article 443647.

VCF Software Depot

In VCF 9.1 and later, the VCF software depot operates alongside SDDC Manager to coordinate depot downloads. In vSphere Foundation 9.1 and later, VCF software depot runs directly within VCF Operations as a standalone component without SDDC Manager.

VCF software depot supports three operating modes for populating the vSphere Lifecycle Manager depot, depending on the network connectivity of the environment:

- For environments with Internet access, VCF software depot communicates directly with `dl.broadcom.com`, appending the required authentication headers based on the activation code configured in VCF Operations.
- For environments without direct Internet access, VCF software depot downloads updates from an offline depot server, which an administrator prepares by using the VCF download tool.
- For fully isolated environments, VCF software depot delivers software metadata and packages from a local depot store that an administrator populates by using the VCF download tool.

vSphere Lifecycle Manager interacts with VCF software depot seamlessly regardless of the Internet access.

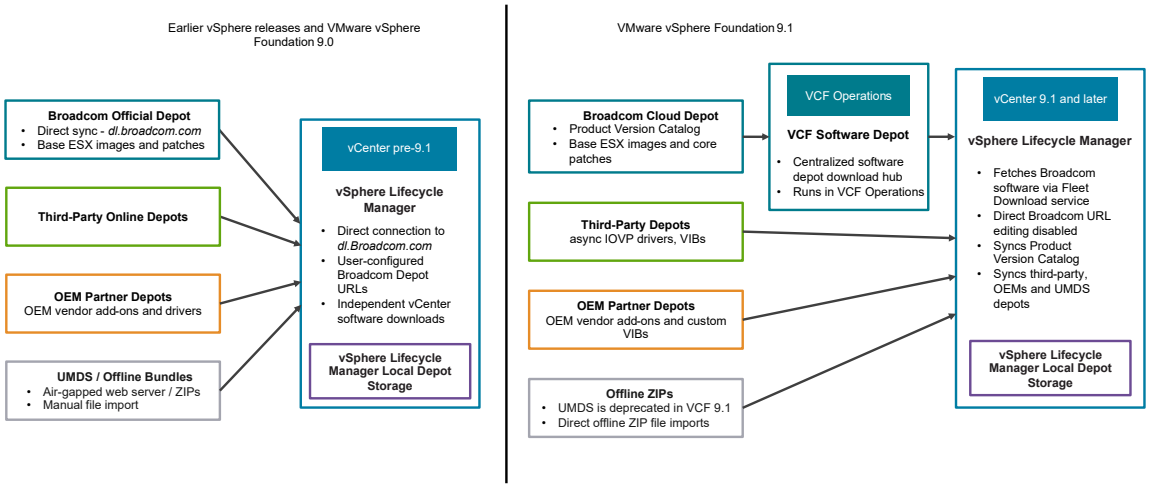
What Is an Online Depot and What Is the Default Broadcom Online Depot

VMware, OEMs, and third-party software providers create and ship their software updates in a well-defined XML file structure, which is called a software depot. Depending on the distribution format of the updates, software depots can be online and offline.

An online depot is the hosted version of the software updates that VMware, OEMs, and third-party software providers ship. In vSphere 9.1, vSphere Lifecycle Manager accesses the online depot through the VCF software depot, which handles authentication automatically by using the configured activation codes.

The Broadcom Online Depot

The unified software depot that Broadcom provides hosts ESX base images, vendor add-ons, ESX-compatible I/O device drivers certified by VMware, and async VMware Tools releases. All software that you need for installing, updating, or customizing your hosts is now centralized in the unified Broadcom software depot. You do not need to work with separate online depots to access OEM and third-party software updates.



Note:
Firmware updates are not hosted in the Broadcom depot. To perform firmware updates, you must install the hardware support manager plug-in that your hardware vendor provides. The plug-in gives you access to depots that contain the necessary firmware and related drivers updates.

You can configure vSphere Lifecycle Manager to also access and use other online depots besides the Broadcom unified depot, for example, third-party depots that contain additional components such as CIM modules. However, working with

additional third-party depots and independent components is rarely necessary. In most cases, the vendor add-ons that are available in the official Broadcom depot provide full OEM customization for ESX.

Synchronization Synchronization is the process during which vSphere Lifecycle Manager downloads the contents of the online depots that you configure it to use to the local vSphere Lifecycle Manager depot. During synchronization, only software metadata is downloaded. The actual payloads are downloaded when they are needed, for example, during staging or remediation. When you deploy vCenter, vSphere Lifecycle Manager synchronizes with the official VMware online depot automatically. After the initial synchronization, you can schedule a download task to run at regular intervals or you can initiate a download task manually.

What Is an Offline Depot

An offline depot, also called an offline bundle, is a ZIP file that you download from the Internet or copy from a media drive and you save on a local or a shared network drive. You then can import the offline bundle to the vSphere Lifecycle Manager depot.

All software updates hosted in the unified Broadcom depot are also available as offline bundles, which you can download from the Broadcom Support Portal Downloads site. You can also download offline bundles from the websites of third-party vendors.

In addition to distributing an `offline.zip` file, or offline bundle, and a custom ISO image, OEMs distribute an `Add-on.zip` file that contains the delta between the OEM custom image and the respective base image that VMware provides. For more information about OEM add-ons, see Software Packaging Units That vSphere Lifecycle Manager Can Consume.

Import Import is the operation through which you upload the contents of an offline bundle into the vSphere Lifecycle Manager depot. During an import operation, both the software metadata and the actual payloads are downloaded into the vSphere Lifecycle Manager depot.

In vCenter 9.0 and 9.1, importing ISO images to the vSphere Lifecycle Manager depot is no longer supported, and the **Imported ISOs** tab has been removed. Upgrades to ESX 9.x can only be performed using vSphere Lifecycle Manager images. Baselines in 9.1 cannot perform host upgrades and are restricted exclusively to minor patching of legacy ESX 8.x hosts using offline ZIP bundles.

You cannot use an ISO image for clusters that you manage with a vSphere Lifecycle Manager image.

Software Deliverables and Their Corresponding Distribution Formats

Software Vendor	Software Deliverable	Software Distribution Formats
VMware / Broadcom	ESX base images and host patches	• Unified Broadcom Online Depot (VCF software depot) • VCF download tool patch store • Offline bundles (ZIP files) imported manually
OEMs (Dell, HPE, Lenovo, etc.)	Vendor Add-ons and Custom Drivers	• Unified Broadcom Online Depot / OEM Online Depots • Offline bundles (ZIP files / Add-on ZIPs)
Third-Party Vendors	Components (I/O Drivers, VIBs)	For device drivers that are certified by VMware: • Offline bundles (ZIP files) For other third-party software that is verified and certified by OEMs, for example I/O filters, CIM module: • Third-Party Online Depots • Offline bundles (ZIP files)

vSphere Lifecycle Manager Download Sources

The vSphere Lifecycle Manager download source is the place from which vSphere Lifecycle Manager downloads software updates.

In vSphere Foundation 9.1, the default download source for vSphere Lifecycle Manager is VCF software depot. The VCF software depot manages the connection to the Broadcom online depot by using the configured activation codes. You do not need to manually configure Broadcom depot URLs in vSphere Lifecycle Manager.

VCF Download Tool Shared Repository

For environments without access to the Internet, you can configure vSphere Lifecycle Manager to use a VCF Download Tool shared repository as its download source. When you configure vSphere Lifecycle Manager to use a VCF Download Tool repository, the synchronization of update metadata is not triggered immediately. The metadata is downloaded according to the configured download schedule or when you initiate the download. When you use a VCF Download Tool repository as a download source for vSphere Lifecycle Manager, only the metadata of the updates is downloaded and stored in the vSphere Lifecycle Manager depot. The actual payload is downloaded during staging or remediation.

You can configure the VCF Download Tool repository to download and store the compatibility data bundle. See Recommended Images.

Cluster Depot Overrides (ROBO Deployments)

In Remote Office / Branch Office (ROBO) environments, use the VCF software depot to centrally manage and distribute software depots to remote sites. If a remote cluster must download updates from a local web server instead of VCF software depot, you can configure a depot override for that cluster. A depot override configures vSphere Lifecycle Manager to use a local depot with updates for a particular cluster instead of the depot that all clusters in that vCenter instance use by default. For more information, see Manage Depot Overrides for a Cluster or a Standalone Host.

Browsing the vSphere Lifecycle Manager Depot

You can use vSphere Client to view and browse the contents of the vSphere Lifecycle Manager depot.

You can view the vSphere Lifecycle Manager depot in the vSphere Lifecycle Manager home view. The contents of the vSphere Lifecycle Manager depot are displayed on two different tabs: **Software Depot** and **Updates**.

Software Depot

On the **Software Depot** tab, you can view all VMware base images, vendor add-ons, and components that are available in the vSphere Lifecycle Manager depot.

You can use the **ESXi Versions**, **Vendor Addons**, and **Component** links at the top of the tab for easier navigation through the lists.

The **ESXi Versions** list contains all base images available in the depot together with information about the version, release date, and category for each image. When you select an image from the list, an information panel appears on the right. The panel displays a list of all components that the base image applies to a host upon remediation.

The **Vendor Addons** list contains all vendor add-ons available in the depot together with information about the version, release date, and category for each add-on. When you select an add-on from the list, an information panel appears on the right. The panel displays information about the components that the add-on applies to the host and the components that the add-on removes from a host upon remediation.

The **Component** list contains all components that are available in the depot together with information about the version, release date, and category for each component. When you select a component from the list, an information panel appears on the right. The panel displays information about the VIBs that the component contains.

You can filter the **Component** list so that it displays only independent components or all components available in the vSphere Lifecycle Manager depot. Independent components are components that are not part of a vendor add-on.

You use the ESX images, vendor add-ons, and components visible on the **Software Depot** tab to set up images that you can use to manage hosts in clusters collectively. You store the setup images in the vSphere Lifecycle Manager Image Library. See Working with Image Library.

Updates

On the **Updates** tab, you can see all components available in the vSphere Lifecycle Manager depot as bulletins. You can use the **Filter by Baseline** drop-down menu to view only the bulletins that are part of a particular baseline.

When you select a bulletin from the list, additional information appears below the bulletins list. In the bottom pane, you see information about the baselines that include the selected bulletin.

You use the bulletins visible on the **Updates** tab to create baselines and baseline groups.

Because the official Broadcom depot hosts certified partner content in addition to VMware content, the **Updates** tab displays a broader set of OEM bulletins, for example vendor add-ons and VMware-certified device drivers. Some of these bulletins might have dependencies that must be pulled into the baselines that you create, so that the remediation against those baselines is successful. As a best practice, always consult the KB article for an individual bulletin to find information about its deployment specifics and required dependencies before including the bulletin in your baselines.

Changes are also introduced in the way VMware content is packaged. As a result, you might see additional bulletins on the **Updates** tab at patch and update releases. Those bulletins are usually of the Enhancement or BugFix category. When you include those bulletins in a baseline, you might need to also include a base ESX bulletin in that baseline. As a best practice, to ensure successful application of patches and updates, always include the appropriate rollup bulletin into your baselines. You can use the **Show only rollup updates** toggle switch that is on the **Updates** tab to filter the list of bulletins.

Working With the vSphere Lifecycle Manager Depot

The vSphere Lifecycle Manager synchronizes to its download source regularly and automatically. But you can change the contents of the vSphere Lifecycle Manager depot by manually importing or deleting updates or ISO images or by triggering synchronization at a convenient time.

Import Updates to the vSphere Lifecycle Manager Depot

You can use an offline bundle in ZIP format and import updates to the vSphere Lifecycle Manager depot manually. When you import offline bundles, you add both the update metadata and actual payload to the vSphere Lifecycle Manager depot.

- Verify that the updates that you import are in ZIP format.
- Required privileges: **VMware vSphere Lifecycle Manager** > **Upload File** > **Upload File**.

You use the import option to populate the vSphere Lifecycle Manager depot with updates from an offline bundle. Apart from the legacy patches and extensions, an offline bundle can also contain an ESX base image, a vendor add-on, or third-party software, for example, asynchronous drivers specific to the OEM hardware requirements. For more information about base images, vendor add-ons, and components, see Software Packaging Units That vSphere Lifecycle Manager Can Consume.

If you want to use vSphere Lifecycle Manager baselines, you can import offline bundles that contain patches and extensions for hosts that run ESX 8.0 and later. In that case, you can use the contents of the offline bundle only for host patching operations. If you import an OEM offline bundle that contains an ESX image of a version earlier than 8.0, you cannot use the image for upgrade operations.

If you want to use vSphere Lifecycle Manager images, you can import offline bundles that contain software for hosts that run ESX 8.0 and later. In that case, you can use the contents of the offline bundle to set up vSphere Lifecycle Manager images, which you can use to upgrade a standalone host or multiple ESX hosts collectively.

1. Navigate to the vSphere Lifecycle Manager home view.
   a) In vSphere Client, select **Menu** > **Lifecycle Manager**.
   b) Select a vCenter system from the **Lifecycle Manager** drop-down menu.

      The drop-down menu is available only when multiple vCenter systems are connected by a common vCenter Single Sign-On domain. By selecting a vCenter system, you specify which vSphere Lifecycle Manager instance you want to administer.
2. Select **Actions** > **Import Updates** at the top of the vSphere Lifecycle Manager home view.

   The **Import Update Resources** dialog box opens.

3. Enter a URL or browse to an offline bundle in ZIP format on your local machine.

   If the upload fails, check whether the structure of the ZIP file is correct and whether the vSphere Lifecycle Manager network settings are set up correctly.

4. Click **Import**.

   The Import updates task appears in the **Recent Tasks** pane.

You imported updates to the vSphere Lifecycle Manager depot. vSphere Lifecycle Manager automatically generates new image recommendations for the clusters or hosts that already have generated recommended images. However, if the imported updates are solution components only, vSphere Lifecycle Manager does not generate new recommendations automatically.

You can view the imported patches, extension, and base image on the **Updates** and **Software Depot** tabs in the vSphere Lifecycle Manager home view.

You can view the imported ESX images, vendor add-ons, and additional components on the **Software Depot** tab in the vSphere Lifecycle Manager home view.

Synchronize the vSphere Lifecycle Manager Depot

Instead of waiting for the predefined download task to run as scheduled, you can update your local vSphere Lifecycle Manager depot immediately.

At regular configurable intervals, vSphere Lifecycle Manager downloads updates through the VCF software depot. VCF software depot retrieves content from the Broadcom online depot in online mode, or from a VCF download tool shared repository in offline mode.

Regardless of the download schedule, you can initiate synchronization between the vSphere Lifecycle Manager depot and the configured download sources. Similar to scheduled synchronization, when you initiate synchronization manually, vSphere Lifecycle Manager downloads software from the download sources that VCF software depot manages. For more information about configuring the vSphere Lifecycle Manager download sources, see Configuring the vSphere Lifecycle Manager Download Sources.

During synchronization, vSphere Lifecycle Manager downloads only the update metadata, the actual payloads are downloaded during staging or remediation.

1. Navigate to the vSphere Lifecycle Manager home view.
   a) In vSphere Client, select **Menu** > **Lifecycle Manager**.
   b) Select a vCenter system from the **Lifecycle Manager** drop-down menu.

      The drop-down menu is available only when multiple vCenter systems are connected by a common vCenter Single Sign-On domain. By selecting a vCenter system, you specify which vSphere Lifecycle Manager instance you want to administer.

2. Select **Actions** > **Sync Updates** at the top of the vSphere Lifecycle Manager home view.

   The Sync updates task appears in the **Recent Tasks** pane.

You downloaded updates to the vSphere Lifecycle Manager depot. vSphere Lifecycle Manager automatically generates new image recommendations for the clusters that already have generated recommended images. However, if the updates are related to downloading solution components only, vSphere Lifecycle Manager does not generate new recommendations automatically.

You can view the downloaded patches and extension on the **Updates** tab in the vSphere Lifecycle Manager home view.

You can view the downloaded ESX images, vendor add-ons, and components on the **Software Depot** tab in the vSphere Lifecycle Manager home view.

Configuring the vSphere Lifecycle Manager Download Sources

Configure the download source for vSphere Lifecycle Manager. In vSphere 9.1, the VCF software depot is the default download source. For environments without Internet access, configure a VCF download tool shared repository.

In vSphere 9.1, the default download source for vSphere Lifecycle Manager is the VCF software depot. The VCF software depot manages the connection to the Broadcom online depot by using the configured activation codes. You do not need to manually configure Broadcom depot URLs in vSphere Lifecycle Manager. For information about activation codes, see Broadcom knowledge base article 443647.

For environments without access to the Internet, configure a VCF download tool shared repository as the download source. An administrator populates the repository by using the VCF download tool, and the VCF software depot retrieves content from it in offline mode.

vSphere Lifecycle Manager downloads only the metadata and not the actual binary payload of the updates. Downloading the metadata saves disk space and network bandwidth. The availability of regularly updated metadata in the vSphere Lifecycle Manager depot lets you perform compliance checks on hosts at any time.

Whatever the download source, vSphere Lifecycle Manager downloads the following types of information:

- Metadata about all ESX 8.x updates regardless of whether you have hosts of such versions in your environment.

  Note:

  In vSphere 9.x, the vSphere Lifecycle Manager depot contains also the metadata about the I/O Vendor Program (IOVP) program drivers for vSphere 7.x releases.
- Patch recalls for ESX 8x hosts.

  vSphere Lifecycle Manager supports the recall of patches for hosts that are running ESX 8.0 or later. A patch is recalled when it has problems or potential issues. After you scan the hosts in your environment, vSphere Lifecycle Manager alerts you if the recalled patch has been installed on any host. Recalled patches cannot be installed on hosts with vSphere Lifecycle Manager. vSphere Lifecycle Manager deletes all the recalled patches from the vSphere Lifecycle Manager depot. After a patch that fixes the problem is released, vSphere Lifecycle Manager downloads the new patch to its depot.

  If you have already installed the problematic patch, vSphere Lifecycle Manager notifies you that a fix is available and prompts you to apply the new patch.

Downloading host patches from the Broadcom online depot through the VCF software depot is a secure process.

- Patches are cryptographically signed with the VMware private keys. Before you try to install a patch on a host, the host verifies the signature.
- VCF software depot downloads the patch metadata and patch binaries over SSL connections. vSphere Lifecycle Manager verifies both the validity of the SSL certificates and the common name in the certificates. The common name in the certificates must match the names of the servers from which vSphere Lifecycle Manager downloads the patches. vSphere Lifecycle Manager downloads the patch metadata and binaries only after successful verification of the SSL certificates.

Download Sources

If your environment has access to the Internet, VCF software depot uses the default connection settings to download updates to the vSphere Lifecycle Manager depot. VCF software depot manages the connection to the Broadcom online depot automatically. You do not need to manually configure download URLs.

In environments that lack Internet connectivity, you can point vSphere Lifecycle Manager to a shared repository that an administrator creates and maintains by using the VCF download tool. VCF software depot retrieves content from this repository in offline mode.

For more information about VCF download tool, see Setting Up and Using the VCF Download Tool.

The default configuration is for the vSphere Lifecycle Manager to download information directly from the Internet. However, you can change the download source at any time. Changing the download source from a shared repository to the Internet and the reverse is a change in the vSphere Lifecycle Manager configuration. The two options are mutually exclusive. You cannot download updates from the Internet and a shared repository at the same time.

By default, vSphere Lifecycle Manager is configured to use the VCF software depot as the download source. VCF software depot manages the connection to the unified Broadcom online depot. When you deploy vCenter, synchronization through VCF software depot is triggered automatically. When you change the default download source, synchronization to the new download source is not triggered automatically. The synchronization task runs as per its schedule. To download

new data, you must run the **VMware vSphere Lifecycle Manager Update Download** task or trigger synchronization manually.

The **VMware vSphere Lifecycle Manager Update Download** task is a scheduled task that runs at regular intervals. You can change the schedule, and you can also trigger the **VMware vSphere Lifecycle Manager Update Download** task independently of its schedule.

If the **VMware vSphere Lifecycle Manager Update Download** task is running when you apply the new configuration settings, the task continues to use the old settings until it finishes. The next time the download task starts, vSphere Lifecycle Manager uses the new settings.

Using a Proxy Server

vSphere Lifecycle Manager does not manage the proxy configuration for depot downloads independently. VCF software depot uses the proxy settings of the VCF Operations instance or SDDC Manager where it runs.

Configure vSphere Lifecycle Manager to Use the Internet as a Download Source

If your environment has access to the Internet, vSphere Lifecycle Manager downloads ESX images, vendor add-ons, and other components from the Broadcom online depot to the local vSphere Lifecycle Manager depot through the VCF software depot. The VCF software depot manages the connection automatically by using the configured activation codes.

Required privileges: **VMware vSphere Lifecycle Manager** > **Configure**

The Internet is the default download source for vSphere Lifecycle Manager. The VCF software depot operates in online mode and communicates directly with the Broadcom online depot. Downloading takes place at configurable regular intervals. To initiate downloading of updates regardless of the download schedule, see Synchronize the vSphere Lifecycle Manager Depot .

1. Navigate to the vSphere Lifecycle Manager home view.
   a) In vSphere Client, select **Menu** > **Lifecycle Manager**.
   b) Select a vCenter system from the **Lifecycle Manager** drop-down menu.

      The drop-down menu is available only when multiple vCenter systems are connected by a common vCenter Single Sign-On domain. By selecting a vCenter system, you specify which vSphere Lifecycle Manager instance you want to administer.
2. On the **Settings** tab, select **Administration** > **Download Sources**.
3. Click the **Change Download Source** button.

   The **Change Download Source Type** dialog box opens.
4. Select the **Download directly from the internet** option and click **Save**.

Configure vSphere Lifecycle Manager to Use a Shared Repository as a Download Source

When direct Internet access is unavailable, configure vSphere Lifecycle Manager to use a VCF download tool shared repository as the download source for ESX images, vendor add-ons, and additional components. VCF software depot retrieves content from the repository in offline mode.

- Create a shared repository by using VCF download tool and host the repository on a web server or a local disk.
- Verify that VCF download tool is of version compatible with the version of vSphere Lifecycle Manager that you are using. For more information about compatibility, see Setting Up and Using the VCF Download Tool.
- Required privileges: **VMware vSphere Lifecycle Manager** > **Configure**.

You cannot use folders on a network drive as a shared repository. vSphere Lifecycle Manager does not download updates from folders on a network share in the Microsoft Windows Uniform Naming Convention form (such as `\\<server_name>\shared`), or on a mapped network drive (for example, `Z:\`). Repositories must be hosted on an HTTP/HTTPS web server or accessible through a valid Linux file system path on the vCenter appliance.

The downloading of updates takes place at configurable regular intervals. To initiate downloading of updates regardless of the download schedule, see Synchronize the vSphere Lifecycle Manager Depot .

1. Navigate to the vSphere Lifecycle Manager home view.
   a) In vSphere Client, select **Menu** > **Lifecycle Manager**.
   b) Select a vCenter system from the **Lifecycle Manager** drop-down menu.

      The drop-down menu is available only when multiple vCenter systems are connected by a common vCenter Single Sign-On domain. By selecting a vCenter system, you specify which vSphere Lifecycle Manager instance you want to administer.
2. On the **Settings** tab, select **Administration** > **Download Sources**.
3. Click the **Change Download Source** button.

   The **Change Download Source Type** dialog box opens.
4. Select the **Download from a UMDS shared repository** option and enter the path or URL address to the shared repository.
   - Web server (HTTP/HTTPS) - Enter the URL pointing directly to the ESX host patch location in the VCF download tool directory structure.

     Example: `https://<web-server-address>/depotStore/PROD/COMP/ESX_HOST/patch-store/`
   - Local appliance disk/mount - Enter the absolute file system path on the vCenter appliance where the download files or mounted media reside.

     Example: `/storage/updatemgr/depotStore/` or `/mnt/usb/`
5. Click **Save**.

   vCenter validates the URL or path. Upon successful validation, vSphere Lifecycle Manager sets the shared repository as its active download source. If the validation fails, vSphere Lifecycle Manager reports a reason for the failure.

   Important:

   If the updates in the folder that you specify are downloaded with a VCF download tool version that is not compatible with the vCenter version that you use, the validation fails and you receive an error message.

The shared repository is used as the main source for downloading software updates.

Using a Folder or a Web Server as a Shared Repository

You can use a folder or a web server as a shared repository.

- When you use a folder as a shared repository, *`depotStore`* is the path to the top-level directory that stores the patches and notifications copied from the downloaded binaries with the VCF download tool.

  For example, use VCF download tool to download the patches and notifications to a folder `/depotStore/`, then manually copy only the host binaries from the `/depotStore/PROD/COMP/ESX_HOST/patch-store/` to a plugged-in USB device on the physical machine where VCF download tool is installed. Then, plug in the USB device to the physical machine where vSphere Lifecycle Manager runs. The device is mapped as `/mnt/usb` and the folder to configure as a shared repository for vSphere Lifecycle Manager is `/mnt/usb`.
- When you use a web server as a shared repository, *`depotStore`* is the path to the top-level directory on the web server that stores the ESX patches downloaded with the VCF download tool.

  For example, copy the ESX patches and notifications from VCF download tool to `/depotStore`. If the folder is configured on a web server and is accessible from other physical machines at the URL `http://example.com/depotStore/`, the URL to configure as a shared repository in vSphere Lifecycle Manager is `http://example.com/depotStore/PROD/COMP/ESX_HOST/patch-store/`. This URL contains only the ESX patches downloaded with the VCF download tool.

After changing the download source to a shared repository, initiate a manual synchronization task (**Actions** > **Sync Updates**) or run the scheduled **VMware vSphere Lifecycle Manager Update Download** task to populate the local vSphere Lifecycle Manager depot with the new metadata.

Run the VMware vSphere Lifecycle Manager Update Download Task

If you change the download source, you must run the VMware vSphere Lifecycle Manager Update Download task to download any new updates.

1. In the vSphere Client, navigate to a vCenter instance.
2. On the **Configure** tab, select **Scheduled Tasks**.
3. In the **Scheduled Tasks** pane, select the **VMware vSphere Lifecycle Manager Update Download** task and click **Run**.

You can see the running task that is listed in the **Recent Tasks** pane.

Add a New Download Source

You can add a new download source for vSphere Lifecycle Manager by providing a URL to the online depot or the VCF download tool repository that you want to use. Additionally, you can edit or delete a download source. You can also temporarily stop vSphere Lifecycle Manager downloading updates from a particular download source.

Add a New Download Source

If you use the Internet as a download source for updates, you can add URL addresses to third-party online depots. vSphere Lifecycle Manager downloads software updates from all the online depots that you configured it to use. Update metadata are downloaded from the online depots to the local vSphere Lifecycle Manager depot.

- Verify that vSphere Lifecycle Manager is configured to use the Internet or VCF software depot as its download source.
- Required privileges: **VMware vSphere Lifecycle ManagerConfigure**

The default download source for official ESX base images, patches, vendor add-ons, and VMware-certified drivers is automatically managed through the VCF software depot using central activation codes. See Broadcom knowledge base article 443647. You cannot manually add, edit, or delete official Broadcom depot URLs (`dl.broadcom.com`) in vSphere Lifecycle Manager.

Legacy customer token URLs, see Broadcom knowledge base article 390121, are deprecated and automatically cleaned up upon VCF software depot registration.

Downloading updates takes place at configurable regular intervals. To initiate the downloading of updates regardless of the download schedule, see Synchronize the vSphere Lifecycle Manager Depot .

1. Navigate to the vSphere Lifecycle Manager home view.
   a) In vSphere Client, select **Menu** > **Lifecycle Manager**.
   b) Select a vCenter system from the **Lifecycle Manager** drop-down menu.

      The drop-down menu is available only when multiple vCenter systems are connected by a common vCenter Single Sign-On domain. By selecting a vCenter system, you specify which vSphere Lifecycle Manager instance you want to administer.
2. On the **Settings** tab, select **Administration** > **Download Sources**.
3. On the **Internet Download Sources** pane, click **New**.

   The **New Download Source** dialog box opens.
4. Enter a URL address to a new third-party download source..

   vSphere Lifecycle Manager supports both HTTP and HTTPS URL addresses. Use HTTPS URL addresses to download data securely. The URL address that you add must be complete and must point to a valid online depot containing an `index.xml` file that defines the vendor and component index.

   Note:

   Upstream proxy settings configured in vCenter or VCF Operations apply automatically when vSphere Lifecycle Manager connects to custom third-party download sources.

5. Optional: Enter a short description for the download source.
6. Click **Save**.

The new URL location is added to the list of download sources and downloading from it is enabled by default. Metadata is downloaded during the next scheduled download task, or immediately when you initiate a manual **Sync Updates** action.

Modify a Download Source

You can edit or delete a download source from the list of vSphere Lifecycle Manager download sources. You can also allow or disallow vSphere Lifecycle Manager to download updates from a particular download source.

Required privileges: **VMware vSphere Lifecycle Manager** > **Configure**

1. Navigate to the vSphere Lifecycle Manager home view.
   a) In vSphere Client, select **Menu** > **Lifecycle Manager**.
   b) Select a vCenter system from the **Lifecycle Manager** drop-down menu.

      The drop-down menu is available only when multiple vCenter systems are connected by a common vCenter Single Sign-On domain. By selecting a vCenter system, you specify which vSphere Lifecycle Manager instance you want to administer.
2. On the **Settings** tab, select **Administration** > **Download Sources**.
3. In the **Internet Download Sources** pane, select a URL address from the list of download sources and select your task.
   - Click **Edit** to edit the source URL or the description for the selected download source.
   - Click **Enable** or **Disable** to allow or disallow downloading from the selected download source.
   - Click **Delete** to delete the selected download source.

     Note:
     You cannot edit or delete the default VMware download source for ESX updates. You can only allow or disallow vSphere Lifecycle Manager to use it for downloading update metadata from it.

Configure the vSphere Lifecycle Manager Automatic Download Task

Downloading host updates and related metadata is a predefined automatic process that you can modify. The automatic download task is enabled by default and starts immediately after you deploy vCenter. After the initial download, the task runs according to its schedule.

- Verify that the VCF software depot providing software updates to vSphere Lifecycle Manager has access to the Internet or VCF download tool is configured with an offline shared repository.
- Required privileges: **VMware vSphere Lifecycle Manager** > **Configure**.

The default schedule settings ensure frequent checks, but you can change the schedule if your environment requires you to adjust the frequency of the checks.

If you need the latest software updates, you might want to reduce the time interval between the checks for updates. By contrast, if you are not concerned about the latest updates, if you want to reduce the network traffic, or if you cannot access the update servers, you might want to increase the time interval between the checks for updates.

The automatic download of update metadata is enabled by default and the default task name is VMware vSphere Lifecycle Manager Update Download. You can change the configuration of the task.

1. Navigate to the vSphere Lifecycle Manager home view.
   a) In vSphere Client, select **Menu** > **Lifecycle Manager**.
   b) Select a vCenter system from the **Lifecycle Manager** drop-down menu.

      The drop-down menu is available only when multiple vCenter systems are connected by a common vCenter Single Sign-On domain. By selecting a vCenter system, you specify which vSphere Lifecycle Manager instance you want to administer.

2. On the **Settings** tab, select **Administration** > **Automatic Download**.
3. In the **Automatic Download Settings** pane, click the **Edit** button.
   The **Edit Automatic Download Settings** dialog box opens.
4. Select the **Enable Automatic Download** check box and configure the schedule and settings for the download.
   To receive notification emails after the download task finishes, you must configure mail settings for the vSphere Client. For more information, see the *vCenter and Host Management* documentation.
5. Click **Save** to save your changes and close the dialog box.

The automatic download task runs according to the schedule you configured.

Setting Up and Using the VCF Download Tool

In VCF 9.1, the VCF download tool is the command-line utility that you can use to download and manage software binaries and metadata that are required from vSphere Lifecycle Manager.

In VCF 9.1, vCenter no longer connects to the Internet for software depot access. Instead, VCF Operations acts as the egress endpoint, retrieving content from the Broadcom online depot or from a VCF download tool shared repository, based on the configured VCF software depot operating mode.

For security reasons and deployment restrictions, vSphere, including vSphere Lifecycle Manager, might be deployed in a secured or air-gapped network without direct access to the Internet. vSphere Lifecycle Manager requires access to software update metadata and patch information to function properly. In such an environment, you can install VCF download tool on a computer that has Internet access to download upgrades, patch binaries, and patch metadata. You can then export the downloads to a portable media drive on an internal web server so they become accessible as a shared repository.

> **Important:**
>
> The URL of the unified Broadcom online depot is `dl.broadcom.com`. You must include the download activation code, see Broadcom knowledge base article 443647, with your CLI requests when downloading software using the VCF download tool.
